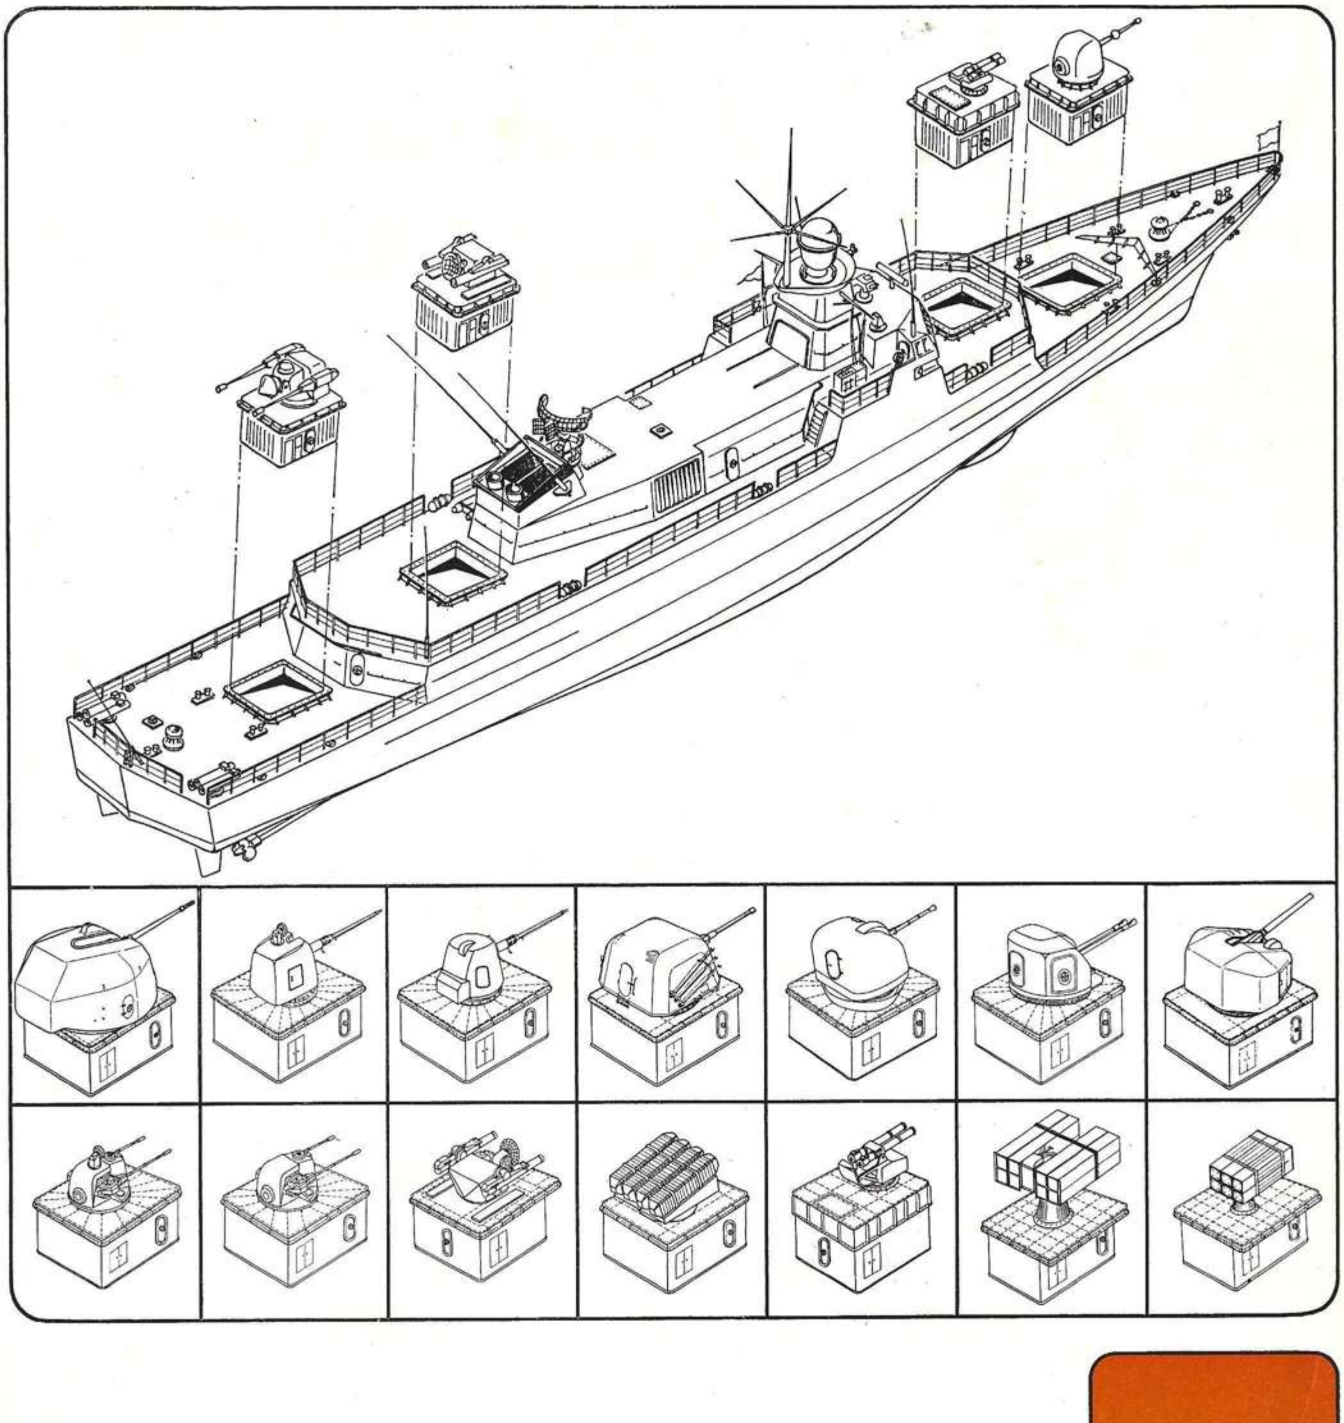
JANE'S WEAPON SYSTEMS 1974-75

Think ahead!

Standardisation of warship design by using the Blohm + Voss system of containerised weapon and electronic systems.



Blohm+Voss

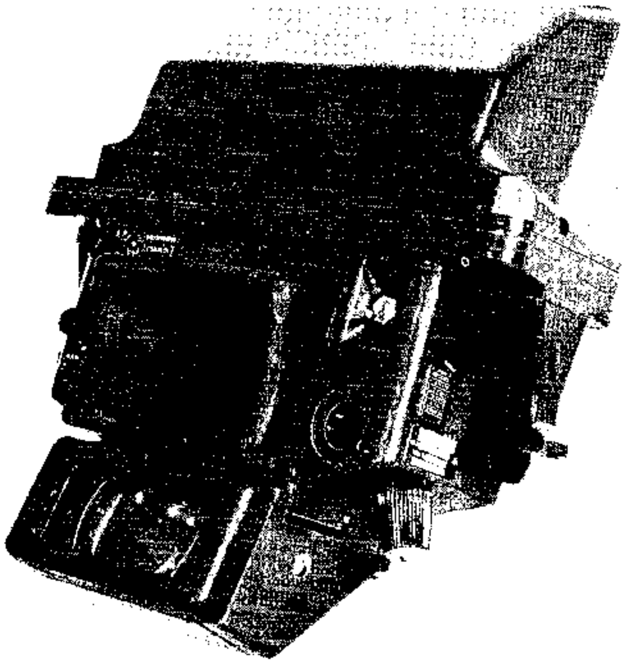
Blohm+Voss AG · 2 Hamburg 1 · P.O. Box 720 · Tel. 040/3061

PASSIVE NIGHT SIGHTS

For:

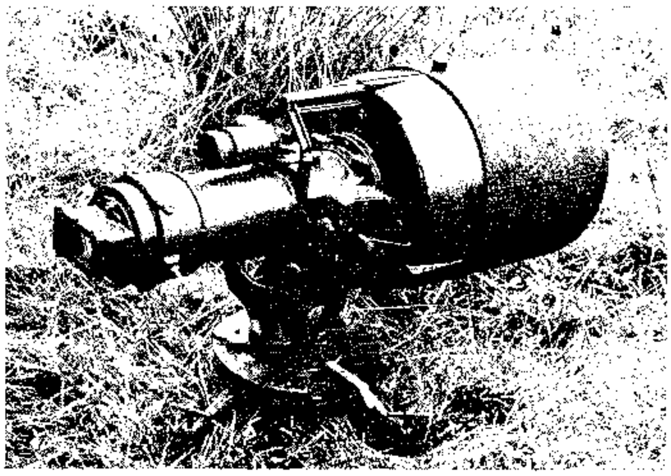
WEAPON AIMING

Small Weapon
Sight—'Trilite'



VEHICLE DRIVING

Passive Driving
periscope for
armoured fighting
vehicles



SURVEILLANCE

Night observation
device for
Artillery observation

For full details of the above and the other night vision equipment in our range:

- Crew served weapon sights.
- Airborne surveillance sights.
- 2nd generation infantry weapon sights.
- 2nd generation night vision lenses.

STRENGTH IN DEFENCE

Sperry Gyroscope is a major Defence contractor and supplies numerous systems and instruments to the navies, armies and air forces of the world.

Typical equipment supplied includes:

- ☐ **Aircraft instruments, nav/attack platforms and data recorders.**
- ☐ **Naval compasses, SINS, lightweight fire control and mine counter measures.**
- ☐ **Omega automatic navigation for ships and aircraft.**
- ☐ **Missile and torpedo guidance and control, safety and arming systems.**
- ☐ **Digital computers, memory storage and message switching systems.**
- ☐ **Navigation and gunfire control systems for fighting vehicles.**

AEROSPATIALE's Tactical Missile Division has designed, developed and delivered more than 350,000 weapon systems, over half of them for export.

First generation, manually guided missiles: ENTAC, SS 11, SS 12M, AS 12, AS 20, AS 30.

Second generation missiles with automatic command to line-of-sight, both simple to operate and highly accurate:

HARPON, AS 30 IR,

ROLAND (surface-to-air), MILAN and HOT (anti-tank), developed jointly with MBB Germany in the EUROMISSILE organization.

EXOCET, surface-to-surface weapon system to arm naval craft of all sizes, from fast patrol boats to cruisers, as well as airplanes and helicopters (tests now underway).

Studies of the submarine-launched EXOCET are going ahead and a coastal defence version is also planned (fixed and mobile missile batteries).

EXOCET has been ordered by the French Navy and many others.

PLUTON, surface-to-surface tactical nuclear missile.

CT 20 target drones and derived systems, used as standard equipment for the testing of surface-to-air missiles.

R 20, battlefield reconnaissance drone (by day and by night).

• CLUSTER BOMBS

The BL 755 Cluster Bomb is highly effective against tanks and other armoured vehicles, aircraft, transport, patrol boats and personnel. It weighs a nominal 273 kg (600 lb), needs only a simple sighting system and can be delivered from tree top level.

• RETARDED BOMBS

Complementary to the cluster weapon No. 117 and 118 Retarding Tails can be fitted to a range of 245-454 kg (500-1000 lb) HE bombs to achieve very low-level attacks against the larger target where concentrated HE is required.

The photograph above shows BL 755 Cluster Bombs and 454 kg (1000 lb) Retarded Bombs on the HS Harrier.

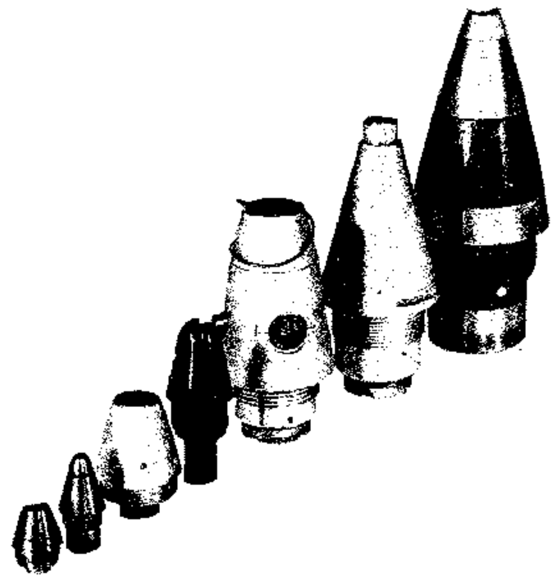
BORLETTI

Fuses for all applications: ground, sea, air



The Borletti Company established in 1896 to manufacture high precision mechanical products, has since 1914 co-operated with the Italian Military Authorities in the development of a number of clock devices for military purposes. Its Ordnance Division has subsequently developed and manufactured timing devices and a wide range of percussion, time and proximity fuses for artillery shells, rockets, land and sea mines, airborne bombs and demolition charges. Design and development facilities are also available to undertake studies on new fuses or timing devices. The Company in past years has been assigned some of the most important fuse contracts under the U.S. Off Shore Procurement programme.

Most NATO and SEATO Services are equipped with Borletti fuses and timing devices.

Manufacturing facilities include up-dated high precision machinery, automatic assembly machines, and full X-Ray services for inspection requirements.

Italian Army Inspection Teams are permanently stationed at the Borletti Ordnance Plants.

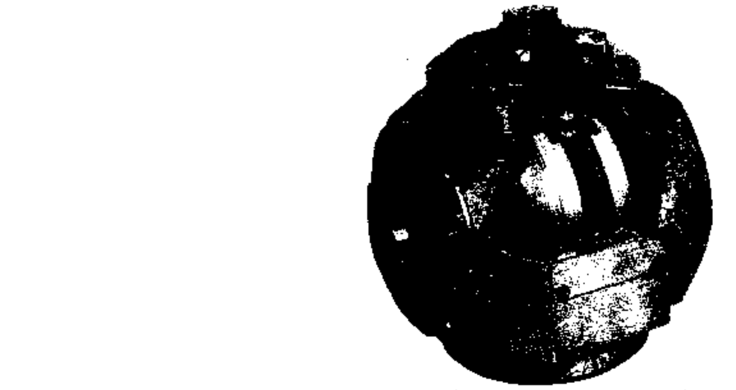
This is the heart



for ships heading and vertical reference systems

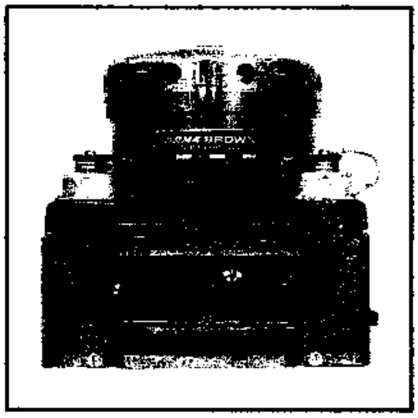
with a proven MTBF in excess of 50,000 hours

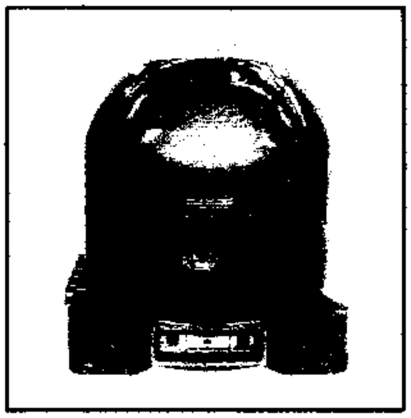
Combined navigation and fire control stabilisation

The Arma-Brown Sensitive Element (also selected for the N.C.S.I.) is used in both the azimuth and vertical reference systems. Integrating the two provides a relatively inexpensive, accurate reference for fire control stabilisation. The compass can function independently to avoid duplication of services.

Arma Brown Gyro Compass MK.1 MOD.5

With remote control unit allowing directional gyro mode to be selected at extreme latitudes and during high speed manoeuvres and Coarse/Fine synchro outputs equally suited for feeding Navigational or Stabilisation systems.



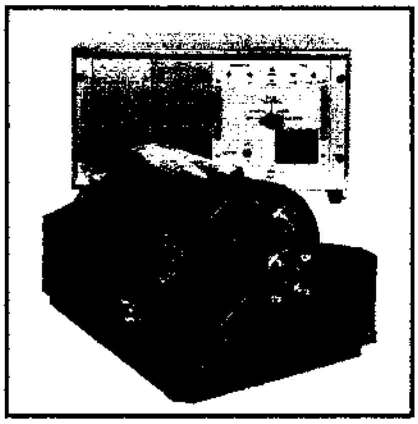


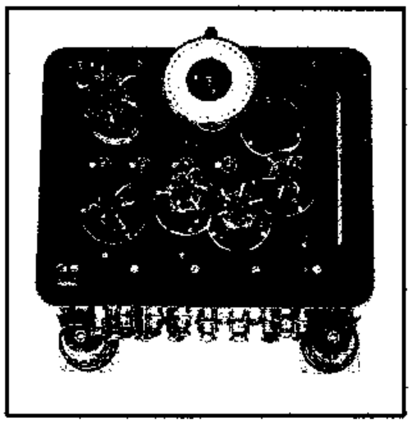
Arma Brown Gyro Compass MK.7

This compass is basically a MK.1 Mod.5 unit in a vertically stabilised gimbal mount offering the same North Seeking/Directional Gyro capability with improved performance in vessels subject to heavy pitch and roll characteristics.

Vertical Reference Gyro

The reference consists of a single gyroscopic element slaved to the vertical by two pendulums with computer corrected errors due to ships motion and earths rotation giving a basic accuracy of ± 3 mins of arc.





Coarse/Fine Retransmission Units

Available with various input configurations and outputs tailored to individual requirements; interfacing with Autopilot, Radar, Sonar, Direction Finder, Roll and Pitch stabilisers and Fire Control systems. Self Alignment ensures maximum state of equipment readiness.

For further information contact the Marketing Manager.

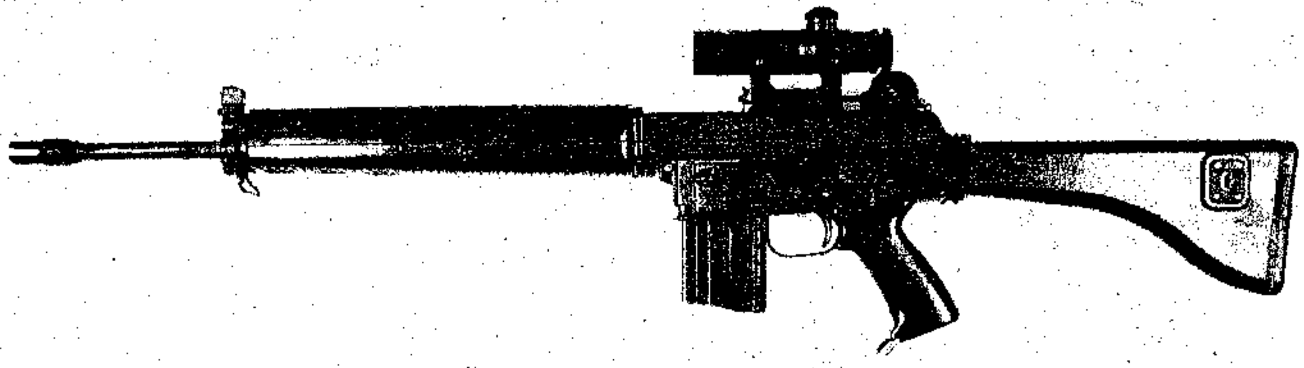
STERLING SUB MACHINE GUN 9 mm MARK 4 (L2A3)

The standard sub machine guns with the British Forces and in service in over 80 countries in the world. Continues to function in the most adverse conditions of mud, sand, snow and ice. Exceptionally accurate and of renowned reliability. Illustrated with optional bayonet. Also available as a police carbine, i.e. semi-automatic fire only.

STERLING PATCHETT SUB MACHINE GUN 9 mm MARK 5 (L34A1)

Developed to meet a requirement for a fully silenced weapon. It retains all the other features of the Mark 4 and uses standard 9mm Parabellum ammunition. The bullet is slowed to sub-sonic speeds by the silencing arrangements giving a truly silent weapon. There is nothing to wear out in the built in silencer and thousands of rounds can be fired without attention except normal cleaning. Also available as a police carbine.



STERLING AR 18 5·56 mm COMBAT RIFLE

(Shown with immediately detachable 3x telescopic sight)

Designed by Armalite Inc. of the U S A who were also responsible for the AR 15 which was re-designated the M16 and made in large quantities for the U S Forces by Colts.
By improving on the best design features of the AR 15, the AR 18 gives outstanding performance and is considerably cheaper to manufacture than the M16 as extensive use is made of pressings and machine turned parts with a design requiring a minimum of close tolerances.
Armalite and Sterling have come to an agreement whereby the AR 18 will be manufactured by Sterling and will be known as the Sterling AR 18.
Also available as a police carbine as the Sterling AR 180.

Why we acquired the best technicians in the world...

When we tackle an area where the most important thing is efficiency we aim at being first in the field; nothing is left to chance, because we will be judged by our results alone.

We employ the most experienced men, no matter what field they specialize in: data processing, aerodynamics, electronics, mechanics.

In our choice of analytic and research methods, as in our choice of goals, we are often ahead of the times.

This is why our 1 500 engineers and technicians are several years ahead in the development of certain missiles.

Our range of missiles, such as the "R 530", the "Crotale", the "Martel", the "R 550", the "Super 530", the "Otomat", is suitable for all types of missions: air-to-air, ground-to-air, air-to-surface, surface-to-surface.

The "R 530": an air-to-air attack missile, all altitudes, under all weather conditions: 2 models: electromagnetic and infra-red: standard production for air force and naval interceptors.

The "Crotale": ground-to-air interceptor missile, low altitude, all weather conditions, completely automatic, used with the Thompson-Houston weapon system.

The "Martel": air-to-ground long range missile developed in collaboration with Hawker Siddeley Dynamic. 2 models: anti-radar and TV guided.

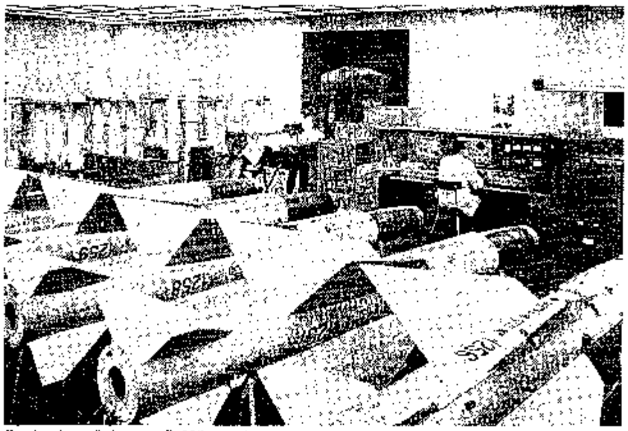
The "R 550": air-to-air missile designed for "dog fight" combat, has the best performance of any missile for short-range and tight manœuvre.

The "Super 530": high altitude, air-to-air interceptor missile for the Mirage F1 weapon system.

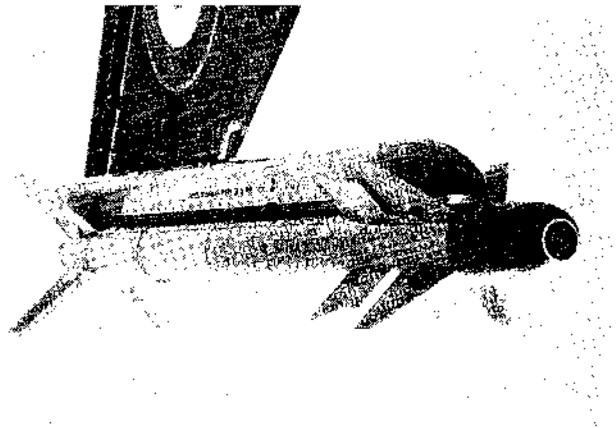
The "Otomat": all-azimuth, anti-ship missile: can be fired from ship, plane or helicopter.

Matra also produces non-guided aeronautical weapons:- rocket-launchers drag-chute bombs, special use bombs.

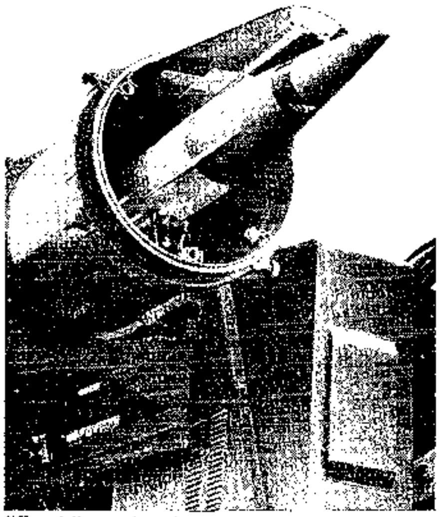
We also undertake Operational Research analyses for French and foreign organizations.



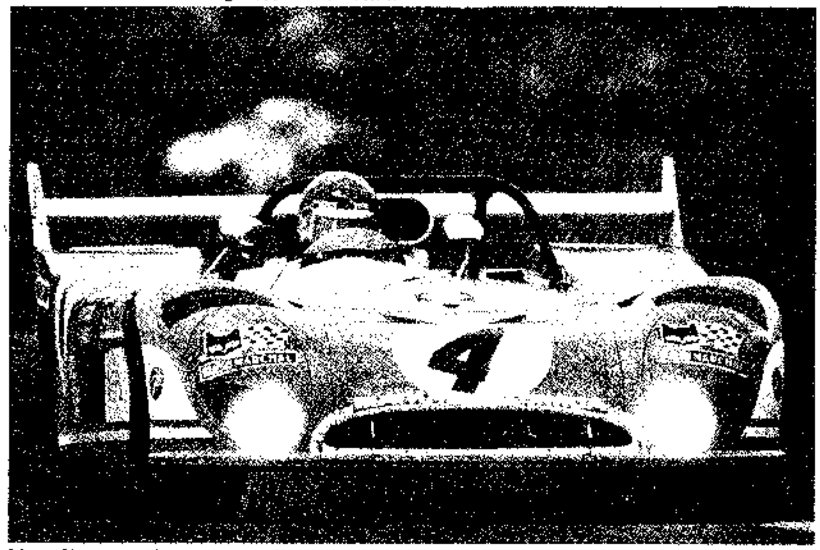
Production of air-to-air R 530 missile.



"Magic" 550 air-to-air missile.



"Crotale" ground-to-air missile.



Matra-Simca: world championship-four makes.

FOREWORD

Much has happened, but little has been achieved, in the world since we wrote the Foreword to the fifth edition of this book. In both military and political contexts (where these are separable) there have been momentous events, many of which created new problems that remain unresolved as we contemplate a new foreword over twelve months later.

Within this short time-span, the government of the UK has been removed from Conservative hands to Socialist and the latter party has won a second mandate only months after ousting their opponents. America, in the same period, underwent the trauma of a Presidential resignation induced by the Watergate scandal. The French President, M. Pompidou, died; while West Germany's Willy Brandt resigned; and surrounding these central changes have been more changes of government—accompanied by varying degrees of violence—in other countries than at any other comparable period that we can recall.

As if these political upheavals alone were not enough to seriously threaten what stability there is, another bloody round has been fought in the Arab/Israeli conflict; there has been war in Cyprus, the Ulster sub-war continues, as does the Vietnamese struggle, and the general level of lawless violence has been sustained by much the same mixture of terrorist-type activities as in the preceeding years.

In the face of such widespread and varied evidence of prevailing instability, it would take an unusually skilled and bold clairvoyant to make a confident prediction of the effect of all this on East-West relations over the next few years.

While feeling that the almost conventional East-versus-West view of world affairs is rapidly becoming too narrow to serve for much longer as the principal fulcrum for debates on world affairs, we are unable to advance proposals for a more suitable approach at this time.

Despite the multiplicity of images crowding our crystal ball, and the limited visibility therein, as it has been our custom to produce some kind of assessment of the present state and likely future trend of international military affairs, we feel we should again attempt this task in order that the reader may relate those hardware developments recorded in this volume to their operational context. We approach this annual venture with more trepidation than usual, and in entreating the indulgence of those more informed than ourselves on this subject we would reiterate that military systems and equipment are the major preoccupation both of ourselves and of this book. More profound or detailed politico-military discussion should be sought elsewhere.

To begin our summary with a glimpse of the obvious, it is evident that there has been no slackening of the arms race between the USA and the Soviet Union; nor is there any sign of a reduction in the Chinese armament effort. It seems apposite to interpose at this point the observation that these efforts—and the armament programmes of other nations, large and small—are being pursued in the face of savage world-wide inflation which seems to defy all efforts to find a cure. Some nations and types of government may be better able than others at forcing through military equipment programmes and projects in the face of inflationary conditions; which injects another parameter to be considered by those attempting to predict the future balance between individual nations or groups of nations.

Returning to the nuclear super-powers, it could indeed be argued that a major outcome of the strategic arms agreements between them has been a considerable increase in the effort devoted to weapon development programmes aimed at circumventing the agreements; and little is now heard of the Pugwash argument, that the development of anti-ballistic missile systems is "de-stabilising", in that it encourages the development of more sophisticated offensive missiles. It is evident that the drive towards greater sophistication is independent of any such encouragement. Details of the new Soviet ICBMs, information on American warhead development and new strategic missile projects which appear in this edition, illustrate the point.

Writing more than two years ago about the 1972 Moscow agreements, we observed that they amounted to little more than a reflection of what both parties had intended to do anyway; and that "little more" could best be summarised as a public declaration that neither dare launch a major nuclear attack on the other, nor create a situation where the other was left with no choice but to launch such an attack.

Much the same, we are sure, is true of the 1974 agreements: the two parties now appear to be content with not much more than a token ABM missile system (and both are almost certainly working on other [cheaper?] defensive techniques); and are now more interested in small-to-middling nuclear warheads than in multi-megaton devices—and in providing these payloads with a better probability of reaching their precise destination; the drive towards improved nuclear missile performance is probably primarily that of maintaining the relative capabilities of the two powers somewhere near the alleged point of balance.

Somewhat further down the scale of nuclear affairs, it is our view that a more dispassionate appraisal of nuclear weapon testing and nuclear weapon proliferation is to be desired. The

STC reports an unusual amount of underwater technology.

STC is actively engaged in equipment for defence.

The world's Navies, for example, depend on the "ears" of dipping and variable depth sonar systems, and for these STC provides the vital cable links.

Dispensing cables for missiles are produced in association with defence experts. And tough STC underwater electric strain cables play an important tactical role in connecting mines and sonarbuoys to their markers.

Some of the STC strategic

developments are still top security. But it doesn't take much fathoming to ascertain that STC has a vital lead in all departments of electric strain technology, from the cables themselves, to sealing glands and terminations.

It could be profitable to consult this depth of experience.

A British Company of ITT

continuation of French tests in the Pacific and the detonation of an Indian nuclear device, during the past twelve months have predictably evinced responses of a different nature. It is hard to deny that the world as a whole would be better off without more nuclear explosions—as indeed it would without many other human malpractices—but in a year in which Britain, China, France, India, Russia and the USA all detonated nuclear devices of some kind—(and Israel declared that nuclear arms were well within her scientific and industrial abilities) it seems less than rational to lambast but two of these nations. Perhaps this really demonstrates either the strength of various nations' predjudices or the relative efficacy of the nuclear nations' respective PR arrangements.

Perhaps the French authorities were a little tactless in their approach to the matter. Perhaps they could have arranged things differently. It seems probable, however, that the reactions of other countries were based to some extent on simple francophobia which in turn probably stems largely from envy of French military independence. The ability of French forces—nuclear and non-nuclear—to deter a potential aggressor can be debated at length; but the fact that France has such forces wholly under her control, backed by an industry which is capable of continuously upgrading them, makes her unique among Western European nations. The British submarine nuclear force is still potentially independent (operationally) and at the present time considerably more potent than the French force; but whereas France has a continuing programme of both submarine and weapon development, the British—although not lacking in either technological manpower or engineering facilities—have a variety of political and psychological obstacles to surmount before they can seriously consider the engineering implications of upgrading the Polaris force.

Again, the British airborne nuclear force—to whatever undisclosed extent it still exists—is also potentially independent; but a modernisation programme would encounter similar obstacles. So far as static and land-mobile missiles are concerned, however, the British forces are dependent—as are all other NATO forces—on American-controlled weapons for their nuclear fire-power.

Many military commentators contend that this is as it should be—that small independent nuclear forces have no rational place in the modern military arena. Hitherto much has been said in favour of the parallel argument that nuclear proliferation is a danger that the world should earnestly seek to avoid. However in the present international situation and having regard to the present and likely future state of weapon development, both arguments seem to us to be of diminishing validity.

In the early days of the NATO alliance there was, on the one hand, a reasonable degree of unanimity among the allies, regarding both the objectives of the alliance as such and the long-term desires of the member nations and, on the other hand, a powerful incentive for the United States to co-operate with Western Europe—the possibility of containing any future conflagration within Europe or at least keeping it away from North America. Today, however, there is little sign of unanimity among the allies—as their reactions to the 1973 Arab-Israeli war, the oil crisis and the Cyprus tragedy have clearly demonstrated; Russian aircraft, submarines and missile developments have caused many responsible Americans to advocate an American withdrawal from Europe. While NATO has an important continuing role in Western defence, as also have many other alliances around the world, no member nation can place absolute reliance on the support of others if its integrity should be threatened.

In these circumstances the arguments in favour of a measure of military self-sufficiency are persuasive.

Short of military intervention there is no way of preventing a nation from arming itself with whatever weapons it is willing and able to beg, borrow, buy or build. If the Indian Government, for example, is determined to make India a nuclear power, can obtain the necessary raw materials and can persuade the Indian electorate to support it, there is very little in practical terms that the rest of the world can do to change the course of events. To argue, as some have, that India cannot afford such a development (or ought not to try to afford it) is futile; the question of a country's "affording" any such activity arises only to the extent to which external purchases are involved: internally, the question is simply one of tailoring the national organisation and standard of living to the fulfilment of national military aspirations. If Britain, for example chooses to seek an improved standard of living while maintaining four times as many men and women in national and local government service as it does in its armed forces, it may well be difficult for the nation to spare much money for defence; but few other countries regard so lavish a bureaucracy as either necessary or desirable, and many have to make do with living standards lower than that which the British have already achieved.

In the Middle East, full scale war broke out again so soon after the foreword to the last edition was written—indeed our speculation upon an oil crisis and its effects appeared in print just as the crisis occurred—that any comments that we might now make on the 1973 Arab-Israeli war would be unlikely to add much of value to the many columns of comment that have already been published.

Much information on Russian weapons emerged from that conflict and has been incorporated in the main text of this edition. So far as the general political scene is concerned,

the observations that we made two years ago are reasonably representative of our current views. The replacement of President Nixon by President Ford in the United States may well lead to modification of American Middle East policy at some time in the future, but any major change appears unlikely while Dr. Kissinger remains in the role of the "Flying Doctor/Arbitrator". This said, it must be recorded with regret, that more than a year after this latest and mostly costly renewal of Arab-Israeli fighting, a lasting solution seems less likely than a further resort to arms.

Before moving on from the Yom Kippur war of 1973, we feel that comment should be made briefly upon one aspect of this conflict which has not been stressed in any of the analyses presented to us. In short, our concern is to draw attention to the severe equipment attrition rates which both sides suffered. The actual figures for tanks, artillery, aircraft, transport and so on are still contested in the columns of military journals, but that these figures were extremely high is not disputed. In addition to losses of equipment, there is some evidence to suggest that the consumption of expendable stores—ammunition and guided weapons, especially—was also at a high level. This in turn prompts us to offer for consideration the proposition that the extraordinary rapidity of hardware depletion suffered by the combatants, and the uncertainties of resupply by their respective armament suppliers, frightened both sides into a more ready acceptance of a ceasefire than purely political or military consideration would have dictated. We presume that the lessons of this feature of the Yom Kippur war will not pass unnoticed by the military authorities of other nations.

It is perhaps too naïve, or too simplistic (in the newer jargon), but one is drawn to ponder the question, "What with soaring attrition rates, and inflation worldwide, who can *afford* a war?" In reply to this rhetorical question we are forced reluctantly to observe that there is no record of a war having been cancelled purely on grounds of cost. And which nation, large or small, denies its citizens the best defence forces and equipment which can be obtained at a cost to the exchequer which is broadly acceptable to the populace? Here we have to admit that some styles of government are better than others at influencing the level of acceptability, but the net result is the same.

If, for the sake of argument, we accept the idealistic concept that in global terms all expenditure on arms represents a waste of the world's resources, until Man changes his nature dramatically it is likely to continue. However, it is our view (and that of others more eminent and more directly involved) that in NATO—and probably elsewhere—our methods of procurement are in themselves wasteful; and while it may not be feasible to halt the grand-scale wastage, we can and should tackle the lesser problem of inefficient equipment procurement.

One trouble is that while NATO arrives at most of its decisions internationally, most operative decisions relating to specific hardware are taken at a national level by individual governments. Discussions leading to the latter decisions are sometimes conducted with incomplete or erroneous ideas of the true circumstances. For example, one can read in the defence debates of various NATO governments, views relating to the various shares of the overall NATO burden shouldered by individual nations—mostly to the effect that 'they' don't do enough and 'we' are doing more than our share.

Most of this argument is sterile, if not actual political humbug; national debate can determine that nation's contribution to NATO but has no mandate in respect of any other nation. Conversely, each NATO member-nation has to live with the decisions of its partners. If this were more widely realised and accepted, in our view NATO would regain some of its earlier strength and unity of purpose. The situation is admirably summarised by the Norwegian Minister of Defence, Alv Jakob Fostervoll, in an article which appeared in the *NATO Review*: "I have often thought that much of the pressure for US troop reductions (in Europe), which the present US Administration has so far successfully resisted, has been the result of lack of information. This picture is based on two fundamental misconceptions—that the US presence in Europe is solely for the benefit of Europe and that the European contribution to defence is negligible." Hastening to add that the US Administration does not share those misconceptions, the Minister went on to quote the Congressional (Randall) Committee of 1972: "It should not be forgotten that the nations of the NATO Alliance constitute the principal world market for US industry outside the United States. In co-operating to ensure the success of NATO, we are, among other things, providing a security for crucially important American interests."

He later cites statistics given by Dr Schlesinger in his Annual Defense report for 1974/75, when the US Secretary of Defense stated, "Of the peacetime forces deployed in the European area, our allies contribute approximately 90 per cent of NATO's ground forces, 80 per cent of the ships and 75 per cent of the aircraft." To supplement this information, Mr Alv Fostervoll wrote, "On a global basis the US and Canada have some 2.2 million men under arms compared with NATO Europe's 3.3 million, in each case one per cent of the population. Moreover, the UK maintains some 17 per cent of its forces outside its national boundaries, and Belgium as much as 33 per cent compared with 11 per cent of US Forces stationed in and around the continent of Europe. There has also been a noticeable shift in the sharing of the defence burden over the last ten years. The Europeans are now providing a greater share of NATO's total defence spending than they were in 1963—and let us remember in this connection that you get more soldiers for any given sum of money in Europe than you would for the same amount in the US."

As we have already said, these figures do not tell the whole story and we have not repeated them here for the simple effect of comparison. Rather, it is our aim to suggest that it is pointless to attempt to make simple comparisons between the constituent parts of what is, or should be, a united entity. In a later issue of *NATO Review* the Deputy Director of the Institute for International Affairs in Rome, Sgr Stefano Silvestri, outlined the impossibility of making such direct comparisons, with some more figures. He wrote, "Everyone knows that defence is also a problem of resources, these vary greatly from country to country. The US Defence Budget (1973-74) provides for an expenditure of 85.2 billion dollars, almost double Holland's GNP, and more than half Britain's GNP. The USA alone supplies about two-thirds of the Alliance's total defence budget (about 126 billion dollars, between Europeans and Americans). These impressive figures deserve careful consideration: there can be no possible comparison between the contribution the Americans can make and the contribution of each single European country. The only acceptable comparison would be between the American budget and the budget of the European countries as a whole. However, while the former is a reality, the latter is still a statistical fiction.

"Concealed behind these European figures there are in fact very different realities." Among them are the numbers of men under arms, the sums spent on equipment, and so on, but defence budgets are not the only elements that divide the allies. One of the most significant other factors is the non-standardisation of armaments—and readers of *Jane's Weapon Systems* will soon be able to call to mind their own favourite example(s) of this feature of life in NATO.

After describing the difficulties of reconciling differences between industry, the Armed Forces, Government, and between partner nations, as affecting the attempts to bring about a greater measure of commonality in defence equipment procurement, Sgr. Silvestri goes on to write:

"The Atlantic Alliance, given its very nature, has to take these national divergences into account. NATO and the various specialised Committees of the Atlantic Alliance which deal with these questions are strictly inter-governmental and they cannot therefore oblige or propose choices that go beyond the limits dictated by the single national policies. The integration of the armed forces is therefore bound to remain more theoretical than real, existing only at the level of the High Commands, (whose function is to plan in peacetime and who would only become operational in wartime) whilst logistics remain a national responsibility. The absence of common policy on defence budgets impedes the overcoming of these limitations. . . . It is not likely that the solution of these problems can ignore certain choices. The existence of a conflict, at times open and at times latent, between the establishment of an actual European weapons industry (and therefore also a certain degree of protectionism) and the interests of the vast American industry, is, for example, evident. Short term costs and efficiency favour the great American industry and bilateral agreements between single European national industries and American corporations. Such a choice, however, condemns NATO to a continuation of the present troubles since it contrasts with a rationalisation at the European level. . . . Until now, the Alliance has not dealt with these questions explicitly. Thus, for example, there has been no official or unofficial reaction to the proposals of rationalisation and concentration of European industries, such as in the case of computers and aeronautics advanced recently by the Commission of the European Economic Community. The Commission's proposals were absurdly limited only to 'civilian sectors' of the industries considered, as if it were really possible to separate the civilian and military sectors when dealing with problems such as the dimensions of an industry, while the organisation in charge of the military sector, that is, NATO, avoids taking a stand or advancing suggestions because of political sensitivity.

"In the near future these problems will become increasingly urgent. From the armed forces' point of view, we are approaching the threshold of amazing technological changes. The enormous developments in electronics and missiles, the development of 'smart' weapons, the progressive relative decline of systems such as the main battle tank or the fighter bomber, the growing electronic warfare environment in which weapons systems must survive to carry out their missions, the appearance of semi-automatic battlefields, of new bomblets and minelets anti-tank systems, etc., signal a real tactical and possibly even strategic revolution. Armed forces that wish to maintain their conventional credibility cannot ignore these developments."

Battle

The great new magazine from Ian Allan that looks at the Armed Services — Land, Sea and Air—Worldwide, Today, Yesterday and Tomorrow

Features include

- **Latest weapon systems**
- **Service and unit news**
- **Analysis of defence policy and strategy**
- **The tasks and responsibilities handled by today's service personnel**
- **Famous ordnance, past and present**
- **Great battles of history**
- **New books on military matters reviewed**
- **Readers opinions, an outspoken correspondence column**

* On sale monthly at all booksellers 40p

Some outstanding Ian Allan titles for your bookshelf

The Pictorial Histories of Major Weapons

Pictorial History of the Machine Gun	Maj. F. W. A. Hobart	£3.45
Pictorial History of the Sub Machine Gun A Military Book Society Selection	Maj. F. W. A. Hobart	£4.95
Pictorial History of the Rifle	G. W. P. Swenson	£2.70
Pictorial History of Swords & Bayonets	R. J. Wilkinson-Latham	£3.50

◄ Mini-Nightviewer Model 4001

The Mini-Nightviewer Model 4001 is a passive image intensifier night vision and night photography device using an 18 mm first generation three-stage cascade intensifier tube with ABC oscillator (automatic brightness control).
Main Features are:

- Miniature in size
- Light in weight
- 25 hours normal operating time per battery
- Fully automatic brightness control and easy focusing plus standard "C" lens mount, make this instrument usable without special instruction
- A large range of commercial lenses; a photo relay lens; a binocular viewer; tripod or pistol grip; give the MINI-NIGHTVIEWER a large mission range with low costs
- It can also be used as a night rifle sight, up to 7.62 mm (with special front lens)

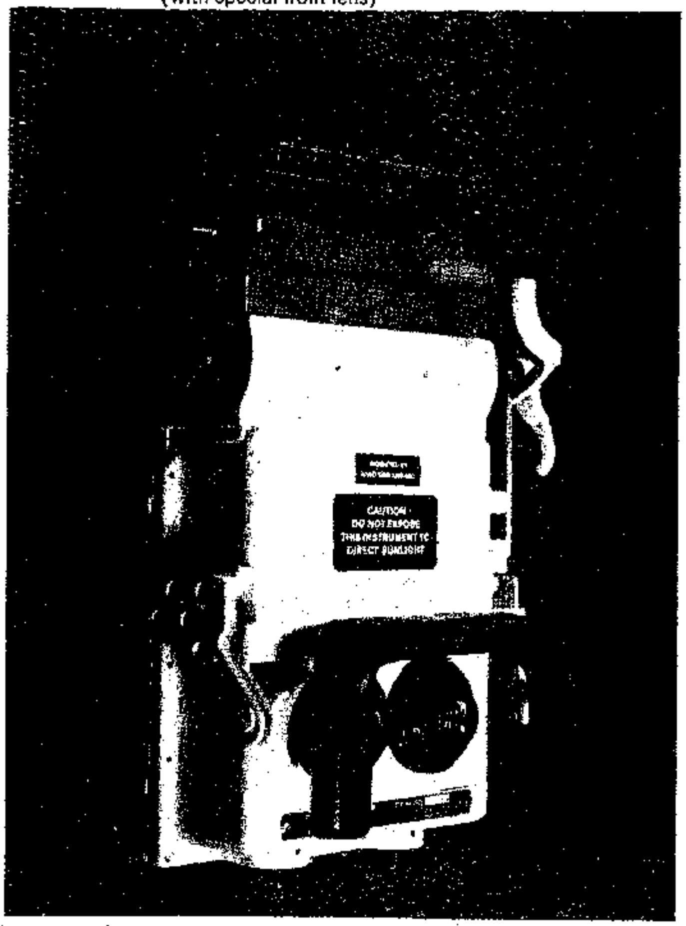
M24P Drivers Periscope ►

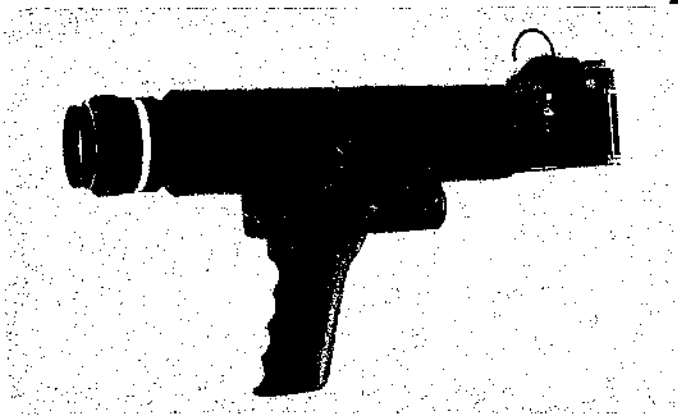
The ICW Passive Night Vision Driving Periscope is suitable for most medium tanks provided with the standard rectangular vision block port This unit is also applicable to all forms of driving, convoy, and light armoured personnel carriers etc., and gives driving and observation down to starlight conditions. No infra red search light is needed as the system is passive.

We also convert the M24IR Drivers Periscope to produce a similar unit.

M24P suitable for the following tanks, M47, M48, M48B, M60, M103, M113

Technical Spec Optical	Magnification 6x Eye Piece
	Diopter adjustment $\pm$ 4
	Eye relief adjustable on Forehead rest
Electrical	Tubes 18 mm three stage ABC
	Gain 30-50,000
	Centre resolution 40 1p/mm
	Edge resolution 7 mm from centre 35 1p/mm
Power Source	28
	24
	12
	6 volts DC at 75 ma or as a portable unit with 2 off batteries life 24 hours.





◄ Midi-Nightviewer Type 105 & Type 106

The Midi-Nightviewer is a passive image intensifier night vision system based on a 25 mm electronic image intensification tube and a configuration suitable for both observation and gun sighting. There are two versions available and in essence they perform the same function, however, the 106 is specially designed to meet the more rugged and exacting specifications of a military device. The 105 can only accept commercial lenses, but the 106 can accept military lenses and therefore can be used as a fully operational military unit with special military lenses. The 106 can also be used as a high grade commercial unit with commercial lenses, however the action of fitting a commercial lens destroys part of the environmental engineering against water and humidity. The Midi-Nightviewer may be hand-held, overhead slung, tripod mounted, rail mounted or carriage mounted, and used with military eyepiece, binocular "large screen" viewer or with any commercial reflex still or motion picture camera.
A range of specially designed lenses will be available as will a whole host of other accessories including a novel camera attachment device which allows the operator to maintain full vision even with a camera fitted.

Specification
Optical

Characteristics with standard 85 mm. F/17

SECTION ONE – SYSTEMS

MISSILE SYSTEMS

DATA ACQUISITION & COUNTERMEASURE SYSTEMS

STRATEGIC SURFACE-TO-SURFACE MISSILES

2200.111

INTRODUCTION:

This section is concerned with current and proposed land-based strategic missile systems. Only five nations have so far seriously attempted the construction of such systems; and one, the United Kingdom, abandoned the attempt at an early stage. Of the others, the USA and the USSR have developed and are developing many different systems and possess large numbers of several different types of operational missile; in France a single land-based strategic missile system has been developed and a version of it with a more powerful warhead is in hand; and in the Chinese People's Republic missile systems are certainly being developed, but little information is available.

It is worth noting that such information as has been published concerning the Chinese missile programme has come from official sources in the USA as does most of the information on Russian missiles. Of the four national strategic missile programmes, therefore, the only one on which significant information is available from sources other than the USA is the French, and even in this case little has been said by the French authorities. While it is only reasonable to expect the information freely available from American or French sources to be less than the total that is in the possession of the authorities concerned, it should be remembered that the information on, say, Minuteman that is withheld for security reasons is not necessarily of the same kind as that which could be, but is not, published concerning, say, the Russian SS-9 missile.

All performance figures quoted for these weapons should, therefore, be treated with some reserve. For the major intercontinental missiles the stated maximum ranges are probably reasonably close to the true values; because if the true performance were markedly less, the missiles would not have the deterrent capability that appears to be accepted as real by those against whom it is directed. With the reconnaissance and related facilities available nowadays to such powers as the USA and the USSR it seems most unlikely that a major deception in this respect could be maintained for long. On the other hand, it may be assumed with some confidence that the published information on developments in multiple warheads and in devices for overcoming or confusing anti-missile defences falls far short of the whole truth.

Although the distinction between "strategic" and "tactical" weapons is commonly encountered in North American and Western European descriptions and discussions of nuclear armaments, it is worth remembering that the distinction, in this form, is essentially American in origin. In the USSR a distinction is made between strategic and other *forces*; and it happens that the Russian strategic rocket forces are primarily equipped with what the USA and its allies now call strategic *weapons*; but the inclusion of some of the smaller Russian missiles in the "strategic" category and the exclusion of some quite large other missiles is essentially arbitrary.

While some well-known missile systems, such as Minuteman and Scarp, can obviously be properly described as strategic surface-to-surface weapons, defining the boundaries of any such classification must to some extent be an arbitrary process. For purposes of selection for inclusion in this section, a strategic surface-to-surface missile has been defined as one that satisfies three criteria. First, its destructive power must be such as to pose a threat either to the strategic missile installations of a potential enemy or to his major population centres. In practical terms, of course, this means that it must carry a nuclear warhead rated in excess of 100 kilotons. Warheads of this order of destructive power are, however, also carried by some of the larger "tactical" nuclear weapons.

Secondly, the operational range of the missile coupled with that of any vehicle from which it can be launched must be such that the missile can be used to threaten a potential enemy's installations or population from a point outside the periphery of the enemy's territory. For a land-based missile the range capability that will enable it to satisfy this criterion obviously depends on the geographical situation; some Russian missiles of quite modest range performance, but capable of carrying large nuclear warheads, are included in this section because they could be used strategically against any of the countries that border the USSR. The third criterion is that the weapon must have been designed for use in such a strategic role.

The terms **intercontinental ballistic missile** (ICBM), **medium-range ballistic missile** (MRBM) and **intermediate range ballistic missile** (IRBM) are used fairly indiscriminately in the literature to describe missiles that are – almost invariably – strategic missiles. It has been suggested that the MRBM description covers missiles with a range capability of up to about 2,500 km. (and we have arbitrarily selected a bottom limit of 1,000 km, thus excluding the American Pershing missile and the Russian Scaleboard – both of which are generally regarded as tactical missiles although they could be said to meet the strategic criteria) the ICBM those capable of travelling more than 6,000 km and the IRBM those in between; but different interpretations are often encountered. Probably the nearest approach to consistency in terminology is the description as an ICBM of any missile capable of covering the distance between the USA and the USSR – and latterly China – in either direction.

For some years these three categories have covered all the surface-launched strategic missiles in operational service in the world. Earlier, a fourth category, the **strategic cruise missile** figured in the US armoury (and the USSR still deploys cruise missiles with nuclear warheads and ranges of several hundreds of kilometres, but they are classed as tactical weapons) but these were withdrawn from service when ICBM deployment in the USA had reached an advanced stage. Cruise missiles have the disadvantage, relative to ballistic missiles, of being easier to intercept and destroy: on the other hand they require much less elaborate launch facilities.

Recently, for reasons which are set out in the discussion of the SALT agreements below, there has been a revival of interest in cruise missiles in the USA. The proposals under consideration at present relate to submarine-launched and air-launched missiles but it is by no means impossible that a land-based version should be added.

Two abbreviations commonly used in strategic-weapons literature are MIRV and MRV – standing for Multiple Independently Targeted Re-entry Vehicle and Multiple Re-entry Vehicle respectively. A missile with an MRV warhead arrangement houses in its final stage a number of warheads which separate before re-entry and reach the ground some distance apart from each other: the pattern of these impacts cannot readily be varied, however, and the extent to which it can be varied at all is strictly limited. With an MIRV system, on the other hand, the multiple warheads contained in the final stage of the missile can be separated out at times and in ways that give not only a wide range of choice of impact pattern but also the opportunity to vary this choice with little difficulty. In principle, MRV and MIRV techniques can be applied to almost any reasonably large missile: in practice, however, since the separate packaging of the individual warheads involves considerable loss of total explosive power, use of the techniques is restricted to the larger land-based missiles and to submarine-launched ballistic missiles.

A third abbreviation – less well-established than the first two but gaining currency – is MARV. This stands for Manoeuvrable Re-Entry Vehicle and is used to denote a re-entry vehicle equipped with means of propulsion and a navigation system which together enable the vehicle to execute limited manoeuvres, after re-entry, to improve system accuracy.

SALT

On 26th May, 1972, three documents were signed, in Moscow, representing the first formal agreements in the Strategic Arms Limitation Talks (SALT) which had been in progress between the USA and the USSR since November 1969. One of these documents was a treaty limiting anti-ballistic missile (ABM) systems: the effects of this are noted later in this section of the book: the second and third documents were respectively an interim agreement on offensive strategic missiles and a protocol defining the effect of this agreement on submarine-launched missiles. These documents are not the only ones that are currently relevant to the strategic balance or imbalance between the two powers: and the dialogue between them continues; at the present time, however, and for the purposes of this introduction, it is sufficient to consider the general effect of the interim agreement and protocol.

Although this section is concerned with land-based strategic missiles, it is necessary in summarising the effect of the Moscow agreement to make reference also to submarine-launched ballistic missiles (SLBM) because the two are treated in the documents as being to some extent interchangeable. The interim agreement, which is intended to remain in force for five years, requires that the total of ICBM and SLBM *launchers* for each country shall be based on the numbers operational or in course of construction on 26th May, 1972, for SLBM, and 1st July, 1972, for ICBM. Beyond the totals at the latter date no further large

Shown in public for the first time in the Moscow parade on November 7th 1973, these large missile containers are believed to be for the new generation of Russian intercontinental ballistic missiles (Novosti) modern ICBM (by which is understood missiles of the size of the Russian SS-9 missile described in entry number **2962.111** below) are to be deployed; but subject to this reservation modernisation and replacement of missiles, launchers and submarines is not restricted. Furthermore, ICBM launchers and launchers on older submarines may be exchanged for an equal number of new SLBM launchers.

The protocol, which has the same duration as the agreement, interprets part of the agreement as meaning that the USA may have not more than 710 SLBM launchers and not more than 44 modern ballistic missile submarines and that the comparable figures for the USSR are 950 launchers and 62 submarines. The distinction between 'older' and 'modern' submarines is not, however, very precise.

Generally, it appears that the effect of the two documents is to permit the USA to maintain a force of 1,710 strategic missile launchers distributed at will in the ranges 1,000 to 1,054 ICBM, 656 to 710 SLBM and 41 to 44 ballistic missile submarines. Similarly the USSR may select options for a total of 2,358 launchers within the ranges 1,408 to 1,618 ICBM, 740 to 950 SLBM and 56 to 62 missile submarines.

Various attempts have been made to translate these options into figures of merit that demonstrate the relative actual and potential strengths of the two forces. Such an assessment, however, borders on the impossible: apart from the options implicit in the figures just given, each country has a wide choice of actual missile types that may be deployed without contravening the agreement: subject to the limitation on the large missiles each may replace its less effective missiles with more modern types. These choices are further complicated by MRV and MIRV possibilities which may be further elaborated at will: on the other hand the effect of maintenance requirements on all types of missiles and the impossibility of keeping all missile submarines permanently on station must be taken into account. Finally, in the total strategic analysis, it has to be remembered that the SALT agreements have not so far covered airborne nuclear missiles at all.

All the avenues of further strategic missile development left open by the agreements are currently being explored by the US authorities and all available evidence suggests that the same is true of the USSR. If anything the level of activity seems to have risen since the agreements were signed. So far as land-based missiles are concerned, available information on these developments is set out in the pages immediately following this introduction: mention should also be made here, however, of the revived US interest in cruise missiles noted above and of suggestions for the air-launching of large ballistic missiles – a technique which, like that of using cruise missiles, is not prohibited by the SALT agreements.

CHINA (PEOPLE'S REPUBLIC)

2048.111
CHINESE ICBM

There is no available detailed information on Chinese intercontinental ballistic missiles. That they have made substantial progress towards the creation of an ICBM force, however, is evidenced by the seriousness with which the US authorities are viewing this development. At a press conference in February 1970 the US Director of Defence Research and Engineering, Dr John S. Foster, reported that during the preceding year the Chinese had been rebuilding their ICBM launching installations and appeared to have reached the point where they were ready to conduct ICBM launches.

Earlier reports had suggested that the whole Chinese missile programme had been delayed – particularly between 1966 and 1968 – possibly because of political harassment of the small group of scientists engaged on the programme. Nevertheless, the US Secretary of Defence, Melvin R. Laird, in his statement on the 1971 defence programme to the House Armed Services Committee in March 1970, said that the start of ICBM flight testing was expected during 1970; and that, although at least three years must almost certainly elapse before such a system could become operational, the Chinese might have as many as 10-25 intercontinental ballistic missiles, with a range of around 10,000 km, in 1975.

These figures were based on the assumption that the Chinese would continue with the development of missiles with liquid-fuelled motors. Although the construction of a solid-propellant manufacturing establishment had been completed it was thought that a solid-propellant ICBM would not be ready for deployment before 1975.

In his statement on the 1972 programme, a year later, Mr Laird told the Committee that the pace of Chinese ICBM development appeared to have been slightly retarded by a shift of emphasis towards the development of IRBMs or MRBMs and nuclear-armed aircraft. Nevertheless he still regarded 10-25 missiles by 1975 as possible with maximum effort. As a part of the programme, it appeared that there had been a limited-range (c. 3,000 km) ICBM shot within China (from north-west Manchuria to western Sinkiang) late in 1970. More recent information, however, suggests that an ICBM test firing could scarcely have occurred as early as this, and that the shot is more likely to have been an IRBM – possibly the second of the two types described in **2049.111** below.

By the Spring of 1973 the US authorities were making some fairly definite pronouncements on the ICBM programme. These may be summarised thus:

(a) A test firing of a missile with a range of some 6,500 km was expected during 1973. The missile would be fired from Lop Nor in Sinkiang.
(b) In its final form this liquid-fuelled missile was expected to have three or four stages, a thermonuclear 3MT warhead and a range of about 11,000 km. Storable liquid propellants would be used and the missile would be a large one – perhaps even longer than the Russian SS-9 (**2962.111**).
(c) Missile deployment was expected to start in 1974/75 and to reach a total of 20 missiles on launchers by 1975/76.
(d) A second-generation solid-propellant ICBM was believed to be in development. This could be deployed in hardened silos towards the end of the 1970s.

The range of 11,000 km suggested in this forecast would make it possible for the weapons to be targeted on cities in the USA. At present, however, it seems that the driving force behind the Chinese ballistic missile programme is the desire to get on terms with the Russian nuclear striking force.

In this connection it is worth noting that, according to reports from the USA, a very large phased-array radar antenna has been constructed in Western China. It is thought that this would provide notice of an attack from about nine-tenths of the Russian ICBM/IRBM force. The purpose of such warning is fairly evidently retaliatory – as was the American BMEWS – and there has as yet been no suggestion that the Chinese are building an ABM system.

Since the American forecast set out above was made there has been little in the way of definite information on Chinese ICBM progress; and American statements have suggested that the programme may have slipped again – possibly by as much as a year. On the other hand if the Chinese have indeed developed a large phased array radar it can reasonably be inferred that they have made substantial progress in military electronics development – notably in high-speed computers and integrated circuits. They may therefore be further advanced technologically than earlier estimates – which put them five years behind the Russians and ten behind the Americans – had suggested. All forecasts of Chinese development progress should therefore be treated with reserve.

2049.111
CHINESE IRBM

Although the Chinese IRBM and MRBM programmes have been subject to delays similar to those that appear to have affected their ICBM programme, it seems fairly clear that there has been a small-scale (15-20) deployment in China of a single-stage IRBM using a storable liquid propellant. This missile is understood to be similar to the first stage of the rocket which launched the first Chinese satellite in April, 1970 and its range has been estimated as lying between 2,500 and 4,000 km. A multi-stage IRBM, also using storable liquid propellants, is said to be in development and may have been deployed: its range is expected to be about 5,500 km – which would enable it to reach Moscow.

Thermonuclear warheads are believed to be carried by some of these MRBM and it is thought that their destructive power is in the region of 2-3MT.

2010.111
CHINESE MRBM

Liquid-fuelled medium-range ballistic missiles similar to the Russian SS-4 MRBM (**2952.111**) have been operational in north-eastern and north-western China since 1970. Like the SS-4, these missiles have a range of about 1,800 km; and it is understood that some 50 are currently deployed – possibly rising to 100 by 1975. The first operational warheads are believed to be smaller than those carried by the Russian missile; a figure of 20 KT has been suggested; but a larger warhead may be fitted to some: in particular it is probable that those which have been most recently deployed carry thermonuclear warheads similar to those carried by the IRBM.

At one time it was thought that this missile would either be deployed in large members or be replaced by solid-fuel missiles. It now seems rather more likely, however, that the Chinese will put the majority of their effort into the ICBM and IRBM programmes; and restrict the MRBM deployment to the minimum consistent with posing a significant threat to Russia while the other missiles are being deployed.

FRANCE

2145.111
SSBS INTERMEDIATE-RANGE BALLISTIC MISSILE TYPE S-2

DESCRIPTION:

SSBS (Sol-Sol-Balistique-Stratégique) is a medium-range two-stage solid-propellant missile, with nuclear warhead, which is stored in and launched from an underground silo. It is maintained in a state of readiness, and preparation for firing and firing are automatic without human intervention in the launch area. Shortly after the firing order is given the silo door is ejected, permitting launching of the missile.

Launch areas are dispersed and hardened to reduce the effects of an enemy attack. Each includes the silo in which the missile is maintained in operational readiness and an annexe housing the automatic launching equipment and servo mechanisms.

DEVELOPMENT:

The government agency concerned is the Direction Techniques des Engins, and the main contractor is the Division Systèmes Balistiques et Spatiaux of Aérospatiale (SNIAS).

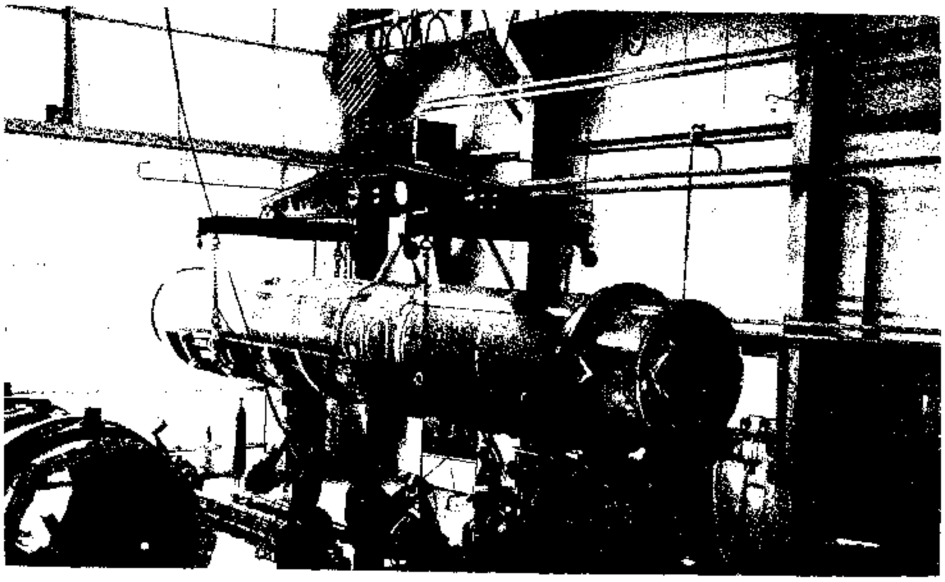
The present production version of the missile is known as the S-2 and is the culmination of study research and development programmes that can be traced back to 1959, first experimental launches having taken place in 1965/66.

STATUS:

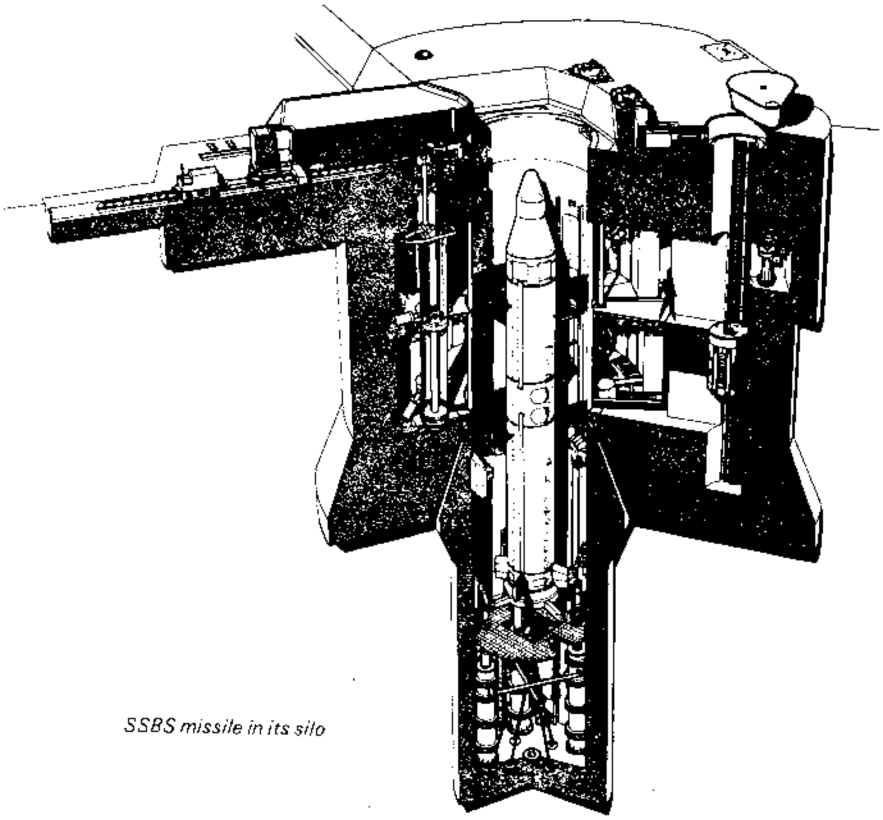
Two groups of nine launch areas have now been established on the Plateau d'Albion. Each group is commanded by a heavily protected, subterranean Central Fire Control Room. These are linked to Strategic Air Force Headquarters by attack proof communications networks. The first of these groups became operational in the summer of 1971 and the second in 1972.

The St Christol Air Base provides the necessary logistical support facilities: emergency and routine repairs, training centre, vector and warhead assembly and storage, etc.

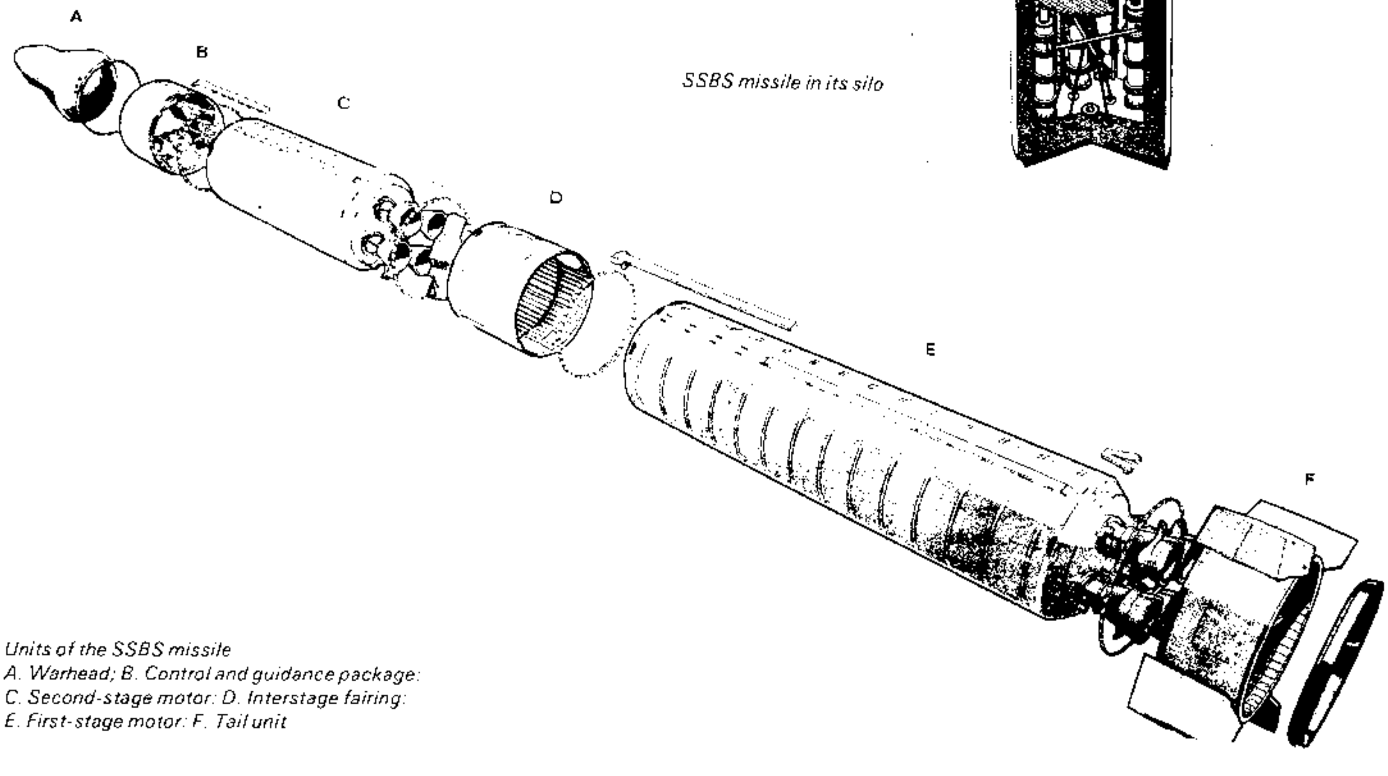
The operational sites cannot be used for experiments and trials. These take place from the Centre d'Essais des Landes near Biscarrosse towards a target area in the Azores.



Assembly of S-2 SSBS missile



SSBS missile in its silo



Units of the SSBS missile
A. Warhead; B. Control and guidance package; C. Second-stage motor; D. Interstage fairing; E. First-stage motor; F. Tail unit

CHARACTERISTICS:

Type: Intermediate-range, silo-launched ballistic missile

Guidance: Inertial

Propulsion:

First Stage: SEP Type 902 motor in maraging metal rolled and welded casing containing 16 metric tons of solid propellant. Four gimballed nozzles for control. Thrust about 55,000 kg.

Second Stage: SEP Type 903 motor with flow-turned Vascojet 1,000 casing containing 10 metric tons of solid propellant. Four gimballed nozzles for control. Thrust about 45,000 kg.

Warhead: Nuclear. 150 kilotons

Dimensions: Length: 14.80 metres
Diameter: 1.50 metres

Launch Weight: approximately 30 metric tons

Range: Approx 1,700 nm (c. 2,750 km)

MANUFACTURERS:

S-2 SSBS missile launch

2163.111
SSBS INTERMEDIATE RANGE BALLISTIC MISSILE TYPE S-3

DESCRIPTION:

In 1973 a new French IRBM programme was initiated to develop the second-generation SSBS S-3 Weapon Systems. This programme entails the deployment of the new missile in a third group of 9 silos, which are to be operational by the end of the decade, and the renovation of the first two groups of S-2 silos (**2145.111**).

The S-3 missile will have a higher performance than the S-2 and will be equipped with a megaton-range thermonuclear warhead and penetration aids.

Improvements to the silos will include both equipment modernisation and system modifications to increase reliability and reduce maintenance costs.

CHARACTERISTICS:

Type: Intermediate-range silo-launched, ballistic missile

Guidance: Inertial

Propulsion:

1st Stage: SEP Type 902 motor (same as S 2)

2nd stage: SEP RITA II motor in wound fibreglass casing containing 6 metric tons of solid propellants. Thrust c. 30,000 kg. Thrust vector control by 4 freon injectors into a single fixed nozzle

Warhead: Thermonuclear (c. 1 MT)

Dimensions: Length: 14 m
Diameter: 1.5 m

Range: c. 1,850 nm (c. 3,000 km)

MANUFACTURERS:

Missile:

Structures —Aérospatiale
Equipment Bay —Aérospatiale
Motors: —G2P

2709.111
ABRES-ADVANCED BALLISTIC RE- ENTRY SYSTEMS

DESCRIPTION:

ABRES is the acronym describing a continuing programme of work on advanced systems sponsored by the USAF's Space and Missile Systems Organisation on behalf of all three US Services. The programme was initiated in 1962 but absorbed some relevant projects that had been started before then.

Obviously the work carried out on the programme is part of a coherent system of investigations planned by the sponsoring body. Equally obviously, the detail of this plan has not been made public; and the information that has seeped out does not present the complete picture – or indeed indicate to which picture some of the pieces belong.

Broadly speaking, however, it can be said that within the total framework of possible operations in the post-ballistic phases of the trajectory of an offensive exo-atmospheric missile there are five main areas of interest:

(a) *Concealment techniques.* Techniques designed to delay detection of the re-entry vehicle by the defence forces by reducing radar cross-section or by using depressed trajectory attack.

(b) *Confusion techniques.* Techniques designed to make it difficult for the defence forces to locate or identify the significant elements of the attacking force. They include radar blackout and saturation devices, such as chaff, and force saturation devices such as decoys. Active ECM may also be included under this heading.

(c) *Evasion techniques.* Techniques designed to make it difficult for the defenders to intercept an incoming warhead even when it has been correctly located and identified. The principal technique here is a form of manoeuvre that invalidates the defence's computation of future position to an extent that makes it difficult, if not impossible, for an ABM missile to be vectored onto a successful intercept course.

(d) *Re-entry techniques*. Constructional techniques aimed at increasing the speed of penetration without loss of accuracy or impairment of function and at increasing the accuracy of the penetration trajectory.

(e) *Target-seeking techniques*. Techniques of manoeuvre during and after re-entry that enable the incoming warhead either to improve its overall accuracy or to regain accuracy after evasive manoeuvres.

The first four groups are generally classified under the heading of "penetration aids" (or "penaids"). Work on such aids has been going on for a long time and operational systems have been deployed in both ICBMs and SLBMs. The ABRES programme, therefore, has not embraced all the work in this field but some of the work forms part of the ABRES programme.

It should also be noted that the work on multiple re-entry vehicles (MRV and MIRV) necessarily involves consideration of some of these techniques. Such work is by no means exclusively concerned with re-entry and post-re-entry manoeuvres, however; indeed a large part of the process of separating and guiding a multiplicity of warheads necessarily occurs during the exo-atmospheric phase of a missile's flight. Although there is some overlap, therefore, the ABRES programmes are not entirely mutually dependent.

It will be evident that there is a close relationship between the third and fifth groups of techniques. Any manoeuvre carried out during the re-entry phase of a missile's flight necessarily introduces possibilities of unforeseeable departures from the planned trajectory resulting from random variations in atmospheric density, winds or turbulence. These random possibilities exist in any case, of course, and, together with imperfections in geodetic surveying, constitute an important source of missile inaccuracy: if the missile is caused to manoeuvre, however, the effects are likely to be accentuated. Not much has been said about the ways in which these difficulties can be overcome: clearly some form of homing technique is required; but equally clearly the simple forms of homing guidance lend themselves too readily to countermeasures. Some discussion of known techniques will be found in the MARV entry below (**2719.111**).

PROJECTS:

Available information on the general nature of some of the component projects and groups of projects of the ABRES programme is listed below, together with names of manufacturers concerned where these are known. Reference should also be made to re-entry vehicle data in entries **2708.111** and **2719.111** below.

A-ball One of the projects taken over by ABRES in 1962 and subsequently renamed BGRV.

ABC Advanced Ballistic Concepts. General title covering several re-entry vehicle projects.

ACE Advanced Control Equipment. USAF project, involving McDonnell Douglas, on manoeuvrable re-entry vehicles. At least two test flights have taken place.

BGRV Hypersonic Boost Glide Re-entry Vehicle. Formerly known as A-ball, this is an early manoeuvrable re-entry vehicle project by McDonnell Douglas, believed to have been first tested in 1967.

DRADS Degradation of Radar Defence Systems. An active ECM homing and jamming project. Raytheon and TRW.

ECM Projects. Numerous active and passive ECM techniques have been covered and have involved Philco-Ford, Raytheon, RCA, Sanders Associates, Sperry Rand and TRW. One Sperry project reported has been the development of noise jamming techniques suitable for use against the Dog House (**2864.153**) central discrimination and handling radars of the Moscow ABM defences (**2945.181**).

FATE Fusing, Arming, Test and Evaluation. A programme co-ordinated by Philco-Ford's Space and Re-entry Systems Division and Stanford Research Institute and covering the functions specified for each new type of re-entry vehicle.

Lapdog An early re-entry vehicle project subsequently re-named MBRV.

LORV Low Observable Re-entry Vehicle. Reduced radar cross-section project by Avco Corporation.

MBRV Manoeuvrable Ballistic Re-entry Vehicle. One of the earlier re-entry vehicle projects undertaken by General Electric. Formerly known as Lapdog it is believed to have been roughly contemporary with A-ball/BGRV.

Optical Countermeasures. Various techniques aimed at altering or camouflaging the signatures of re-entry vehicles.

Re-entry Vehicles. So far as is known, no complete operational re-entry vehicle has been developed under the ABRES umbrella. Major contributions have, however, been made to the Mk 11, 11A, 11B, 11C and 12 re-entry vehicles and some contribution has also been made to the Mk 3 (300 ?) vehicle. Available details of these vehicles are set out in entry **2708.111** below.

REST Re-entry Environment and Systems Technology. Investigations concerning fluid mechanics, flow fields round re-entry vehicles, stability and advanced heat shields. Avco Corporation.

SEE Small Evader Experiment: A recent manoeuvrable re-entry vehicle project by General Electric. Believed to be the latest in this sequence of projects.

MANUFACTURERS:

Twenty-three manufacturers were involved in the ABRES programme when it was first set up but over the years the number has increased to fifty-six. Among these, AVCO, Bendix, Chrysler, General Dynamics, General Electric, General Precision, Hughes, McDonnell Douglas, MIT, Philco-Ford, Raytheon, RCA, Sanders Associates, Sperry Rand, Stanford Research Institute and TRW are known to have been involved in various projects.

2708.111
BALLISTIC MISSILE RE-ENTRY VEHICLES

DESCRIPTION:

Although details of some ballistic missile re-entry vehicles (RV) are given in the entries describing the missiles in which they are used, the following annotated list – although not exhaustive – may be helpful.

Mk 3 See Mk 300 below.

Mk 5 Single-warhead RV with single target capability and yield reported as 1 MT. No penetration aids (penaids). Used on Minuteman I, LGM-30A (**2710.111**).

Mk 6 Large RV with single multi-megaton warhead and three-target selection capability and elaborate penaids. Made by General Electric and used on Titan II (**2826.111**).

Mk 11 Single-warhead RV with two-target capability and yield of about 1 MT. No penaids. Made by AVCO and used on Minuteman I, LGM-30B (**2715.111**).

Mk 11A Single-warhead RV similar to Mk 11 but may differ in warhead yield. Use as Mk 11.

Mk 11B Single-warhead RV with 1-2 MT yield and eight-target selection capability. Incorporates penaid canister, made by Tracor, designated Mk 1 or Mk 1A – difference not known but penaid believed to be mainly if not entirely chaff ("window") and Mk 1A may reflect improvements in dispensing techniques. RV is made by Avco and used on Minuteman II (**2716.111**).

Mk 11C Single-warhead RV similar to Mk 11B but improved and hardened against nuclear weapon effects.

Mk 12 Three-warhead MIRV with yield of 200 KT for each warhead. Complete system including penaids contracted to General Electric and used on Minuteman III (**2717.111**). Post-boost propulsion and control by Bell Aerosystems package.

Mk 12A Currently proposed modified version of Mk 12. Improvements are understood to be aimed at improved capability against hardened targets for Minuteman III (**2717.111**). RV improvements generally will presumably be the responsibility of General Electric; there will also be work for the Atomic Energy Commission in upgrading the nuclear warheads.

Mk 17 Large multimegaton RV with a high degree of accuracy. Cancelled because of funding clash with Mk 12 but also because its evident first-strike potential was out of keeping with the US strategic posture at the time. Originally planned for Poseidon (**1132.411**) as well as Minuteman III (**2717.111**).

Mk 18 RV with multiple unguided RVs for super-saturation. Stemmed from Avco and General Electric/Atomic Energy Commission research and the CRESS (Combined Re-entry Effort in Small Systems) programme. In its early stages the project was known as SWARMS. Project cancelled in favour of Mk 12 and the RV for the Poseidon missile (**1132.411** and see Mk 300 below).

Mk 19 High-yield, high accuracy system first proposed in 1972 but rejected as inconsistent with the spirit of SALT as a result of public and Congressional pressure. Now believed to be on the point of reinstatement because of the increasingly evident need for a hard-target capability in the ICBM force.

Mk 20 High-yield warhead intended ultimately to replace the Mk 12/Mk 12A warheads. For use with Minuteman III it will probably have the same number of warheads as the earlier RVs but will have an improved yield/weight ratio. Not yet in development.

(Mk 100 ?) RV for Polaris A-1 and/or A-2 (**1130.411**). Single thermonuclear warhead with a yield of some 800 KT.

(Mk 200 ?) RV for later model of Polaris A-3 missile (**1131.411**). Three 200 KT MRV thermonuclear warheads.

(Mk 300 ?) Usually referred to as Mk 3 but apparently in separate series from, e.g. Mk 11. RV for Poseidon missile (**1132.411**). Capacity for 14 RVs with or without warheads: currently deployed with 10 MIRV 50 KT thermonuclear warheads plus penaids. Essentially a resurrection of the SWARMS concept with guidance: to some extent based on the Lockheed Agena reconnaissance satellite programme using the restart capability of the Bell Model 8048 engine and using vernier jets for altitude adjustment.

Mk 400 Ballistic RV being developed by Lockheed for the MIRV system of the Trident missile (**2840.411**).

Mk 500 Manoeuvrable RV (MARV) being developed by General Electric for the Trident missile programme.

STATUS:

As indicated for each RV in the above list. In addition to the entry references noted above the ABRES (**2709.111**) and MARV (**2719.111**) entries may also be found useful.

MANUFACTURERS:

Some contractors are named above. Many other companies have played important parts in the specification, development and testing of these vehicles.

2719.111
MARV (MANOEUVRABLE RE-ENTRY VEHICLE) SYSTEMS

INTRODUCTION:

Work on manoeuvrable re-entry vehicles (MARV) for ballistic missiles has been in progress for some time in the USA. Some of this work has been done as part of the general ABRES programme (**2709.111**); but there is also a separate MARV programme for the Mk 500 re-entry vehicle for the US Navy's Trident missile (**2840.411** and see also **2708.111**). Of the two programmes, that associated with ABRES is the more fundamental, since it is concerned with the general problems of RV manoeuvres, whereas the Trident programme is aimed at providing a specific capability for a specific missile.

MARV systems can be used for two quite distinct purposes. On the one hand they can introduce an unpredictable element into the movement of the RV, thus making it more difficult for the defence system to make a successful interception, alternatively they can be used to improve the overall effectiveness of the missile system by providing a terminal guidance function. The two purposes are in one sense mutually opposed, since evasive manoeuvres will tend to diminish system accuracy; but this tendency can be corrected – provided sufficient time and power are available – by following the evasion phase of the re-entry by a terminal guidance phase.

In the recent past MARV development emphasis has been more on evasion techniques for improved penetration than on terminal guidance. The reason for this is that terminal guidance has maximum relevance to attacks on hard targets – "counterforce" operations – whereas during the relevant period the US strategic policy has been one of "assured destruction" and the ICBM force has been assigned to a "countervalue" role and targeted mainly on soft targets. In line with this policy it has been felt that the development of systems that might enable US missiles to destroy Russian missiles in their silos would be dangerously provocative – "destabilising" as the jargon has it. Although some suitable techniques have been known for a decade, therefore, little effort had been applied to using them before the Autumn of 1973.

This situation has now changed. Presumably because of the evident intention of the Russian authorities to press ahead with ICBM/MIRV developments, the US Defence Department included in its FY1975 budget proposals an item for "advanced development of a terminally guided MARV for possible retrofit into both ICBMs and SLBMs" and proposed the allocation of $20 million, to start this programme, out of a total of $120 million for ABRES ($30 million more than the FY1974 total).

DESCRIPTION:

A MARV differs from a non-manoeuvring re-entry vehicle in the provision of a propulsion system, some form of guidance or navigation system and the mechanical wherewithal to convert the commands of the guidance/navigation system into actual RV movements.

It is important to distinguish between the various propulsion systems which may now be incorporated in an advanced ICBM. Minuteman III (**2717.111**), for example, has three solid-propellant rocket stages whose function is to accelerate the payload to the required velocity and place it accurately, using the missile-borne inertial navigation system, on the required trajectory. In that payload, which is a MIRV system, there is a fourth propulsion stage, comprising a main propulsion motor and several peripheral attitude control motors; this system is controlled by a complete guidance package and causes the payload "bus" to make excursions from its initial ballistic trajectory so that the independently targeted warhead RVs can be set on their separate ballistic trajectories. If one or more of these RVs is a MARV then each such MARV will require a further propulsion and guidance system – a fifth stage of propulsion and a third guidance system.

It will readily be apparent that since the MIRV guidance package is referenced to the trajectory established by the main vehicle propulsion and guidance system any inaccuracies introduced by the two guidance systems will be additive; so that – quality for quality – a MIRV system is intrinsically less accurate than a single warhead system. Similarly, a MARV system which executes only evasive manoeuvres and does not incorporate terminal guidance is also intrinsically less accurate than a non-manoeuvring warhead.

Inaccuracies in the main propulsion process and subsequent MIRV operation and evasive manoeuvring can be corrected only by a guidance system which is referenced to something other than a trajectory established in an earlier phase of the missile's flight; and in practical military terms the only suitable type of reference will be some invariant characteristic of the target or its surroundings – some physical feature which cannot readily be altered, disguised or simulated by the enemy. One characteristic which is likely to be suitable in many instances is the physical configuration of the terrain over which the RV must pass on its way to the target.

TERCOM – Terrain Contour Matching

A system which is capable of using physical features in the required manner is known as TERCOM. This is an altitude comparison and pattern recognition system which is used to apply corrections to the inertial navigation system which is carried by the RV and which has otherwise been referenced to the other missile navigation systems as described above.

In TERCOM a radio altimeter is used to measure the true height of the RV above ground level and a pressure altimeter is used to measure pressure altitude. The difference between these two readings gives a measure – though not necessarily an accurate one – of the height of the ground surveyed above some datum level such as sea level. The reading obtained is an average one for a defined area of land beneath the RV. A typical area is a square of side 400 ft (122 m) but larger or smaller areas can be used.

Starting at a point determined by the inertial navigation system, readings for a considerable number – typically 64 – of consecutive contiguous areas of equal size are taken by the system and stored in the system's memory. This chain of readings is then compared with a rectangular matrix of readings for a much larger area of terrain which should include the planned track of the RV and any likely departures from that track. By correlating the measured track with all possible similar tracks in the matrix a track giving the best fit can be discovered and the along-track and cross-track navigation errors can be measured and corrections applied. A single comparison of this type, of course, cannot be expected to give good results but repeated measurements and corrections offer the possibility of satisfactorily accurate navigation.

Since the correlation process is in terms of variations in terrain height above datum rather than absolute height, neither altimeter need be exactly calibrated and the system is substantially independent of variations in barometric pressure. What is important, however, is the preparation of the comparison matrix, this must be prepared beforehand by reconnaissance and in some circumstances this could be difficult.

MAGCOM

TERCOM and systems using similar principles are unusable over long stretches of water (whether liquid or frozen) and may be unsatisfactory over large desert areas. An alternative system, called MAGCOM, uses techniques similar to those of TERCOM but using the contours of the earth's magnetic field for comparison instead of the physical contours of the terrain. Prior reconnaissance for this system is likely to be even more difficult than for TERCOM, but otherwise there seems to be no reason why the system should not function satisfactorily. For the Submarine-Launched Cruise Missile, however, it is understood that the intention is to rely on inertial navigation over water and TERCOM over land – presumably because the whole flight over water will be a single operation controlled by one navigation system the inaccuracy at landfall should not be greater than can be handled by the TERCOM system.

STATUS & MANUFACTURERS:

Development work on TERCOM and MAGCOM has largely been carried out by E-Systems Inc who did some early work on TERCOM-like systems back in the 1960s. It is understood, however, that Boeing, General Dynamics/Electronics and McDonnell Douglas have worked on similar systems more recently. As noted above a TERCOM-type system has been specified for the Submarine-Launched Cruise Missile.

Early studies by Lockheed Missiles & Space recommended a mixed payload for the MIRV of the US Navy's Trident missile (**2840.111**) – consisting partly of non-manoeuvring RVs and partly of MARVs. The two RVs are known as the Mk 400 which is being developed by Lockheed and the Mk 500 – the MARV – which is being developed by General Electric. The future of the latter RV was somewhat uncertain until recently, but it now seems fairly clear that it will be put into service in due course.

Thirdly, as part of the ABRES programme (**2709.111**) McDonnell Douglas have a MARV development in hand. Unlike the other two developments this project is not directly related to a specific missile and its funding, too, has been in some doubt. For the reasons stated in the introductory paragraphs above, however, its future now seems assured – assuming, that is, that the work so far done will be taken as the basis for the MARV development for which provision was made in the FY1975 budget proposals.

2710.111
MINUTEMAN INTERCONTINENTAL BALLISTIC MISSILES

DESCRIPTION:

Minuteman is the general name of a family of a silo-launched solid-propellant intercontinental ballistic missiles now extensively deployed in the USA. Of the four versions of Minuteman that have so far been constructed, three are currently operational with the USAF – Minuteman I (LGM-30B), Minuteman II and Minuteman III. A force modernisation programme which has been in operation since 1964, however, is progressively eliminating Minuteman I, and the 1,000-missile force will, when this programme is complete, consist only of Minuteman II and III 450 of the former and 550 of the latter.

MINUTEMAN I – LGM-30A (**2715.111**) is the original version operational in 1963 but no longer in service

MINUTEMAN I – LGM-30B (**2715.111**) was used to equip the next four wings. It is somewhat longer than the LGM-30A and has a greater range but is otherwise generally similar in design and performance.

MINUTEMAN II – LGM-30F (**2716.111**) became operational with the sixth wing in 1966. This is a more sophisticated weapon with a greater range and more flexible targeting capability than the Minuteman I. It can deliver a heavier payload with greater accuracy. Tracor Mk 1A penetration aids are part of the payload.

MINUTEMAN III – LGM-30G (**2717.111**) incorporates all the Minuteman II improvements and has an improved third stage. It carries the advanced Mk 12 multiple independently targetable re-entry vehicle (MIRV) warhead.

DEVELOPMENT:

Invitations to tender for the original Minuteman contracts were issued early in 1958, and out of fourteen bids made, that of Boeing was accepted in October of that year. In February 1961 the first Minuteman surface launch took place successfully at Cape Kennedy and later in the year the first silo launch was attempted. This was unsuccessful – the missile exploded after first-stage ignition – but the second attempt on November 17th was a success.

Minuteman's production line started to roll in 1962 and the first two flights (20 missiles) were declared operational in Malmstrom AFB, Montana, in December of that year. This base was equipped with its full complement of three squadrons of missiles (total 150) by July 1963 – these missiles being of the LGM-30A pattern – meanwhile deliveries of the LGM-30B version to other bases had begun. These were deployed at four bases at Ellsworth, South Dakota, Minot, North Dakota, Whiteman, Missouri, and Warren, Wyoming. The first of these four AFBs was declared operational in July 1963 and Wing V at Warren was completed in June 1965. Wing V was equipped with 200 missiles and the others with 150, making a total of 800 missiles in all. Meanwhile, in September 1964, the first launch of a Minuteman II missile was made successfully from Cape Kennedy.

Assembly and check-out of Wing VI, the first Minuteman II base, was begun in 1965 and the wing became operational in December 1966. An additional squadron of 50 Minuteman II missiles was deployed adjacent to Wing I by April 1967, bringing the total number in the strategic alert to 1,000. By October of that year, as part of the force modernisation programme, the 150 Minuteman I missiles at Wing IV, Whiteman AFB, had been replaced by Minuteman II missiles. Two months later the first flight of 10 missiles at Wing J had been modernised.

Development of Minuteman III was authorised in the spring of 1966, and the first successful launch was made from Cape Kennedy on August 16, 1968. Initial planning called for Minuteman III to be operational in July 1969, but funding limitations caused a slippage of approximately one year.

Installation of the first squadron of 50 began at Minot AFB, North Dakota, on 18 April 1970, and the first flight of 10 missiles became operational two months later. The first squadron became operational on 8 January 1971 when the fifth flight was handed over to the Strategic Air Command.

Since then the force modernisation programme has been proceeding on the revised schedule and the planned deployment of 550 missiles should be completed in 1975.

Presumably in an attempt to redress the USA/USSR strategic missile balance, however, the USAF are currently pressing for a further extension of MIRV deployment aimed at equipping all 1,000 missiles with triple MIRV warheads. Since at the time we go to press the total number so equipped is probably between 350 and 400, it would seem that such a programme could scarcely be completed before the end of 1978.

OPERATIONAL OORGANISATION:

Missiles are organised in flights of 10 launchers, each flight having its own launch control centre. Five such flights make a squadron and three or more squadrons make a wing.

Geographical dispersion is over very wide areas. Wing I for example is spread over an area of 18,000 square miles in Montana. Missiles are stored ready for launch in individual hardened launch sites each having a surface area of two to three acres. The individual launch silo is nearly 25 metres deep and nearly four metres in diameter with two underground equipment rooms around the silo casing extending more than eight metres below the surface. The flight-launch control centre is buried some 15 metres underground and is a blast-resistant shock-mounted capsule operated by two officers of Strategic Air Command.

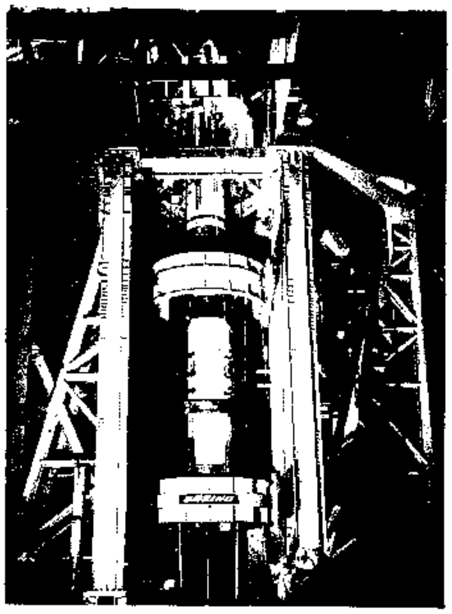
The missile launch sites are unmanned in their normal operating mode of Strategic Alert. In this condition the missile guidance equipment power is on continuously and the missile's own internal computer regularly performs routine checks relating to the missile's readiness for launch. Each site is so deployed that it is at least 5½ kilometres from a launch control centre and at least 9 kilometres from any other launch site.

Although primarily concerned with the control of a flight of missiles, each launch control centre has the capability of controlling a squadron. In each squadron two of these centres are designated as command centres having the capability and responsibility of controlling the entire squadron should the other three centres be incapacitated, and all five are redundantly interconnected so that any one can assume total control of the squadron if necessary. To minimise the effects of human error, launch command is programmed to take place normally as the result of a co-operative team effort by two control centres: in addition any one centre in an entire missile wing can nullify a launch command generated by an individual centre acting independently of the squadrons.

It was announced in January 1966 that Boeing's Missile and Information Systems Division was then designing an airborne launch control system for Minuteman as an alternative to launch control from their underground centres. The qualification testing programme of this system, designed for installation in KC-135 airborne command post aircraft, was completed successfully in the autumn of the same year.

Recently, the US authorities were worried by the possibility of disruption of the command and control system from the airborne command post by EMP (electro-magnetic pulse) interference resulting from nuclear explosions. Guidance hardening modifications have therefore been made and an improved command post arrangement was devised and is known as AABNCP (advanced airborne national command post). Equipment for this system is installed in Boeing 747 aircraft, from which launch commands for Minuteman can be given if necessary.

Another recently-introduced improvement is the Command Data Buffer System. Details of the functioning of this system have not been released, but its purpose is to increase the speed of remote re-targeting of the missiles. It has been reported that the system will enable the command to switch a missile to a new target in 20 minutes – whereas previously it could take up to 36 hours

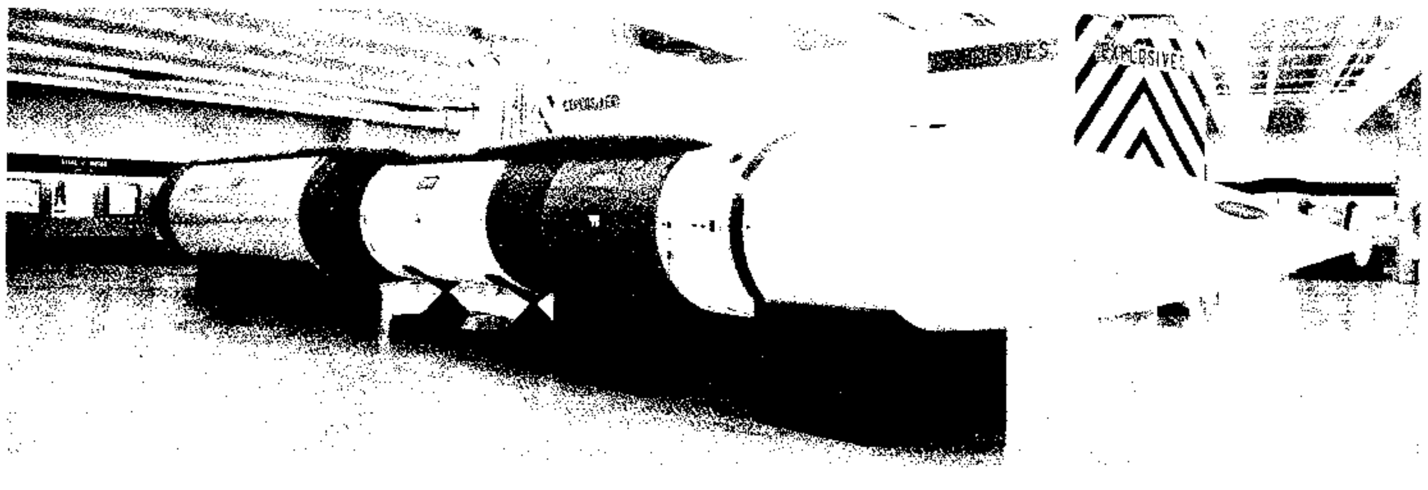


A 700-ton "earthquake machine", developed by Boeing to simulate the effects of nearby nuclear explosions, for testing Minuteman III suspensions

MANUFACTURERS:

Assembly, test and installation of the Minuteman system is the responsibility of the Boeing Aerospace Company, Seattle, Washington, 98124, with TRW Systems providing systems engineering and technical direction. Contractors for control and guidance equipment are the Autonetics Division of Rockwell International. Ground electronics system is by Sylvania.

Thiokol first-stage motors are used on all three missiles as also are Aerojet-General second stage motors. Third-stage motors for Minuteman I and Minuteman II are by Hercules Inc. and that for Minuteman III is by Aerojet-General and Thiokol. Avco ablative-type re-entry vehicles are used on the first two missiles and those for Minuteman III are by General Electric, with Bell Aerosystems as associate contractor for the post-boost propulsion system in the fourth stage.



LGM-30G Minuteman III ICBM

2715.111
MINUTEMAN I INTERCONTINENTAL BALLISTIC MISSILE

DESCRIPTION:

As noted in the general entry on Minuteman missiles (**2710.111**), two versions of this first member of the series were produced and deployed. The earlier version, designated LGM-30A, is no longer operational, having been replaced by later versions, and the following description relates only to the second, slightly larger, version – LGM-30B.

Minuteman I is a three-stage ICBM powered by solid-propellant motors and carrying a single thermonuclear warhead. It is inertially guided but the guidance accuracy is – naturally – not disclosed; all that can be said on this subject is that the combination of its CEP and warhead yield is generally regarded to be insufficient for the missile to be effective against a fully-hardened missile silo in enemy territory.

CHARACTERISTICS:

Service Designation: LGM-30B
Type: 3-stage, solid-propellant, intercontinental ballistic missile
Guidance: Inertial – Rockwell International Autonetics
Propulsion: First stage – Thiokol TU-122 (M-55) approx 91,000 kg st.; Second stage – Aerojet, thrust unknown but probably around 20,000 kg; Third stage – Hercules, thrust approx 16,000 kg. Thrust vector control by four gimballed nozzles is used on all three stages
Re-entry Vehicle: Various types have been used. Currently operational missiles are believed to carry Avco Type 11 and 11A vehicles
Warhead: Thermonuclear single warhead with a yield unofficially reported to be 1 MT
Dimensions: Length 17.0 m; diameter approx 180 cm at the first stage interstage
Launch Weight: Approx 29,400 kg
Speed: More than 24,000 km/h at burn-out
Range: Approx 10,000 km

STATUS:

Operational, but replacement by Minuteman III missiles is expected to be complete not later than 1975.

MANUFACTURERS:

Assembly, test and installation: Boeing Aerospace Company, Seattle, Washington 98124.

Systems engineering: TRW Systems Group, 1 Space Park CR, Redondo Beach, California 90278.

Guidance: Rockwell International Autonetics, 161 Brick St., Princeton, West Virginia 24740.

Propulsion: Aerojet-General Corporation, 9400 E. Flair Drive, El Monte, California 91734; Hercules Inc., 910 Market St, Wilmington, Delaware 19899; Thiokol Chemical Corporation, Bristol Pennsylvania 19007.

Re-entry Vehicle: Avco Systems Division, 201 Lowell St., Wilmington, Massachusetts 01887.

2716.111
MINUTEMAN II INTERCONTINENTAL BALLISTIC MISSILE

DESCRIPTION:

Minuteman II was introduced as a considerably improved version of Minuteman I (**2715.111**). The improvements, however, took the form of an upgrading of the missile's capabilities rather than a radically new departure – as, in some respects, is Minuteman III (**2717.111**). Like Minuteman I it is a three-stage ICBM carrying a single thermonuclear warhead, but it has increased range and azimuth, providing greater targeting coverage, while carrying a larger payload. A more sophisticated guidance system is capable of pre-storing the locations of a larger number of alternative targets and the over-all accuracy of the missile system is greater than for Minuteman I. The increased payload capability enables the missile to carry a larger thermonuclear warhead together with a number of penetration aids.

The first-stage and third-stage motors of Minuteman II are believed to be the same as those and on Minuteman I but the second-stage motor is new.

CHARACTERISTICS:

Service Designation: LGM-30F
Type: 3-stage, solid-propellant, intercontinental ballistic missile
Guidance: Inertial – Rockwell International Autonetics
Propulsion: First stage – Thiokol TU-122 (M-55), approx 91,000 kg st; Second stage – Aerojet SR19-AJ-1, approx 27,500 kg st; Third stage – Hercules, thrust approx 16,000 kg. Thrust vector control on first and third stage motors by four movable nozzles. Second-stage motor has a single nozzle with secondary liquid injection for thrust vector control.
Re-entry Vehicle: Avco Type 11B and 11C with Mark 1 and 1A penetration aids – the latter being supplied by Tracor Inc.
Warhead: Thermonuclear single warhead of a yield unofficially reported as around 2 MT
Dimensions: Length 18.2 m; diameter approx 180 cm at the first stage interstage
Launch Weight: Approx 31,750 kg
Speed: More than 24,000 km/h at burn-out
Range: More than 11,250 km

STATUS:

Operational. According to firm plans at the time of writing, 450 Minuteman II missiles will be kept on the active strength for some years to come. There is, however, pressure from some quarters to replace these missiles by Minuteman IIIs.

MANUFACTURERS:

Assembly, test and installations: Boeing Aerospace Company, Seattle, Washington 98124.

Systems engineering: TRW Systems Group, 1 Space Park CR, Redondo Beach, California 90278.

Guidance: Rockwell International Autonetics, 161 Brick St., Princeton, West Virginia 24740.

Propulsion: Aerojet-General Corporation, 9100 E. Flair Drive, El Monte, California 91734; Hercules Inc., 910 Market St., Wilmington, Delaware 19899; Thiokol Chemical Corporation, Bristol, Pennsylvania 19007.

Re-entry Vehicles: Avco Systems Division, 201 Lovell St., Wilmington, Massachusetts 01887.

Penetration Aids: Tracor Inc., 6500 Tracor Lane, Austin, Texas 78721.

2717.111
MINUTEMAN III INTERCONTINENTAL BALLISTIC MISSILE

DESCRIPTION:

Minuteman III is the most potent weapon in the land-based armoury of the United States. Like Minuteman I and Minuteman II it is basically a three-stage ICBM powered by solid-propellant rocket motors, but it incorporates several features which make it more than a simple improvement on the two earlier members of the series.

Most of the special features relate to the final stage and re-entry system and the most significant, operationally, is the introduction of a MIRV system of three warheads. This MIRV head is essentially a fourth stage of the missile and is powered by a 135 kg thrust motor and manoeuvred by six small pitch and yaw motors and four smaller roll motors. These motors are controlled by the fourth-stage guidance package which also organises the release of the warheads, chaff and decoys from the General Electric re-entry vehicle. The third stage of the missile has also been considerably improved by the introduction of a new motor using fluid-injection thrust-vector control – which gives a finer control of movement than the earlier arrangement of four movable nozzles and which, with improved guidance, enables the missile to carry its large payload over a greater range and at the same time reduce the missile's CEP to about 400 metres.

CHARACTERISTICS:

Service Designation: LGM-30G
Type: 3-stage, solid-propellant, intercontinental ballistic missile
Guidance: Inertial – Rockwell International Autonetics
Propulsion: First stage – Thiokol TV-122 (M-55) approx 91,000 kg st; Second stage – Aerojet SR19-AJ-1, approx 27,500 kg st; Third stage – SR73-AJ-1 Aerojet and Thiokol, approx 15,500 kg st; Post-boost propulsion system — Bell Aerosystems package comprising 135 kg st bi-propellant (nitrogen tetroside/MMH) engine for fore-and-aft control, six 10 kg st engines for pitch and yaw control and four skin-mounted 8 kg st motors for roll control. Propellant tanks are welded shut for long-term silo storage. All motors commanded by fourth-stage guidance package
Re-entry Vehicle: General Electric Mk 12. Normal Minuteman III payload is three MIRV warheads plus chaff and decoys
Warheads: Thermonuclear, approx 200 KT each
Dimensions: Length 18.2 m; diameter 185 cm at first stage interstage
Launch Weight: Approx 24,500 kg
Speed: More than 24,000 km/h at burn-out
Range: More than 13,000 km
CEP: Less than 400 m

STATUS:

Operational. Current programme calls for replacement of all Minuteman I and some Minuteman II missiles by Minuteman III to a total of 550 by the end of 1975. Deployment beyond that point is possible since it is felt in some quarters that the USA should equip all its 1000-missile Minuteman force with MIRV warheads to counter the large Russian strategic missile force.

MANUFACTURERS:

Assembly, test and installation: Boeing Aerospace Company, Seattle, Washington 98124.

Systems engineering: TRW Systems Group, 1 Space Park CR, Redondo Beach, California 90278.

Guidance: Rockwell International Autonetics, 161 Brick St., Princeton, West Virginia 24740.

Propulsion: Aerojet-General Corporation, 9100 E. Flair Drive, El Monte, California 91734;

Minuteman III launch (US Air Force Picture)

Thiokol Chemical Corporation, Bristol, Pennsylvania 19007.

Post-boost Propulsion System: Bell Aerospace Co., Division of Textron Inc., PO Box 1, Buffalo, New York 14240.

Re-entry Vehicle: General Electric Co., 570 Lexington Avenue, New York, NY 10022.

2720.111
MINUTEMAN IV INTERCONTINENTAL BALLISTIC MISSILE

DESCRIPTION:

A range of improvements to the basic Minuteman III ICBM (**2717.111**) has been proposed by the US authorities. It is believed that the intention is to introduce these improvements sequentially, rather than as a complete improvement package; but in either case the effect will be – if the proposals are carried out – to produce a missile which is superior in performance to Minuteman III and operational earlier than the new MX ICBM (**2718.111**). The name "Minuteman IV" has no official status and is introduced here solely for editorial convenience.

The following improvements are believed to be proposed:

1. *Improved propulsion system* involving redesign of the second-stage and third stage motors.
2. *Improved guidance.* An improved system is being developed by the Autonetics Division of Rockwell International and involves major software and minor hardware changes. Aim is to reduce the missile CEP from about 400 m to a little over 200 m. Total cost has been estimated at $120 million with $30 million to be spent in FY 1975.
3. *Improved re-entry vehicles.* First improvement will be the introduction of the Mk 12A RV (**2708.111**), total development cost of which is believed to be in the order of $150 million including about $60 million for improved warheads. Subsequent improvements will probably include the Mk 20 RV (**2708.111**) at a cost of some $400 million and may involve the MARV (**2719.111**) or Pave Pepper (**2839.111**) re-entry projects.
4. *Improved silos.* This aspect of the improvement programme can be separated from the other three, since these improvements are generally applicable to all Minuteman missiles. The general intention is to reduce the susceptibility of the silos to damage resulting from enemy attack by, for example, improving suspension systems.
5. *Operational testing.* Another separable aspect of the programme is the proposal to carry out some Minuteman trials from operational silos as distinct from the test launch sites from which all launches have hitherto been made. In this respect the US authorities consider themselves to be at a disadvantage relative to the USSR where frequent launches are made from operational bases. Information gained from such launches would be a valuable input to the improvement programme.

STATUS:

Generally as indicated in the foregoing notes, subject to the reservations that many of these proposals are, at the time of writing, encountering considerable opposition in Congress.

2718.111
MISSILE-X INTERCONTINENTAL BALLISTIC MISSILE

DESCRIPTION:

Missile-X or MX is the current provisional designation for a new intercontinental ballistic missile which has been under consideration for some time in the USA and which is envisaged as a replacement for – or possibly a supplement to – the Minuteman series of missiles (**2710.111** and **2715-7.111**).

The combined effects of the restrictions imposed by the SALT agreements in 1972 (see **2200.111**) and of the evident determination of the USSR to develop its strategic missile forces at least to the limits permitted by those agreements have concentrated thinking on the new missile; and while, at the time of writing, the final intentions are not clear, it seems likely that the following considerations will influence the final specification.

1. SALT agreements so far do not cover air-launched nuclear weapons: the final version of MX is therefore likely to be suitable for air-launching. Boeing have put forward a proposal for a system based on their 747 aircraft – which could carry four missiles of around 50 tonnes or eight of around 25 tonnes. Alternatively, a new aircraft could be developed. In either case the air-launch technique calls for exceptionally accurate initial navigation references: these are considered to be within the present state of the art – but their reliability under nuclear warfare conditions needs to be considered.
2. Although SALT is taken by the US authorities to restrict deployment of land-mobile strategic missiles there is currently no objection to their development. Since mobile missiles have the advantage of presenting a potential enemy with additional targeting problems it is likely that the possibility of a mobile arrangement will be borne in mind when the MX is finally specified. There were earlier proposals for a mobile Minuteman, but so far as is known no hardware was built.
3. A payload significantly larger than that of Minuteman III is regarded as important by the US authorities. Since SALT prohibits the creation of new silos for larger missiles it is almost certain that the MX will be developed to make maximum use of the existing Minuteman silos. One way of doing this is to use a cold-launch technique – one in which the missile is ejected from the silo by cold gases and first-stage ignition does not occur until after the missile is clear of the silo. This technique makes it possible to dispense with the protective shielding which has to be used in hot-launch silos and thus increase the usual diameter of the Minuteman silo to about 3 metres. A cold-launch technique is already used for launching submarine-born ballistic missiles.
4. Improved re-entry systems are already being studied and developed both for Minuteman and for the US Navy's Trident programme (**2840.411**). Much of this work, some of which is described elsewhere in this section (**2708/9.111** & **2719.111**), will also be applicable to the MX.
5. Much the same is true of propulsion systems. It is believed that a system similar to that developed by Thiokol for the Trident programme is likely to be selected for the MX.

STATUS:

MX is a research project at the time of writing, but the US Defence Department has requested an appropriation for FY 1975 which is nearly ten times as great as that for FY 1974. No programme details are known.

MANUFACTURERS:

Most of the major manufacturers who have been concerned with other US strategic missile systems are either involved in or likely to be involved in the MX programme. In the absence of firmly-designated contractors it would be invidious to select names for mention here.

2839.111
PAVE PEPPER RE-ENTRY PROJECT

DESCRIPTION:

One of several programmes aimed at increasing the effectiveness and operational versatility of US nuclear weapon systems, Pave Pepper is scheduled to start in US Fiscal Year 1975.

The aim of the programme is understood to be the development of small low-yield re-entry vehicles for use with both strategic and tactical missiles and each re-entry vehicle being assigned a specific target. A three-year development programme is envisaged.

Details of missiles with which these re-entry vehicles might be associated have not been released up to the time of writing, nor have the names of any manufacturers concerned been disclosed. The reported relevance of the programme to both strategic and tactical missiles, however, suggests that there may be two sub-programmes involved in the development, with some common features such as the physical configurations and basic construction of the re-entry vehicles. For the tactical application it is possible to imagine an arrangement whereby a Lance (**2682.111**) or Penking (**2765.111**) missile would be required to take out specific targets using, perhaps TGSM dispensing techniques similar to those described in entry **2838.111**, designation and homing systems analogous to the Paveway series (**1533.311**) and miniature nuclear warheads like those described in entry **2725.103**. The Paveway techniques would scarcely be applicable to the strategic use of the system, however: nor would the TGSM dispensing technique in its present form. To design a different dispensing mechanism would presumably present few problems; but the target designation and guidance would appear to require a command system of some kind on the parent missile.

All this is speculation, however, and it may well be wide of the mark.

STATUS:

Project. It is reported that expenditure of $21 million, $38 million and $22 million are envisaged for FY 1975, FY 1976 and FY 1977 respectively.

2826.111
TITAN II INTERCONTINENTAL BALLISTIC MISSILE

DESCRIPTION:

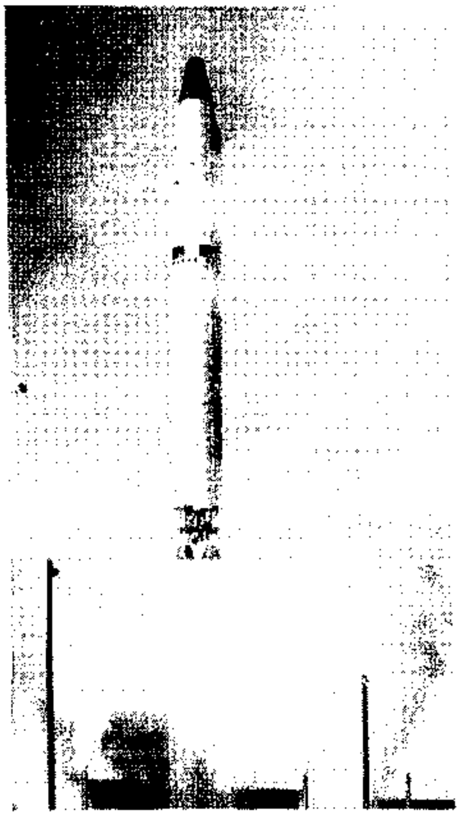
The LGM-25C Titan II is an improved version of the earlier HGM-25A Titan I intercontinental ballistic missile. It carries the largest of all US ICBM payloads and has a launch reaction time of one minute from its fully hardened underground silo.

Titan has been operational with the Strategic Air Command since 1963 and is deployed in three wings of 18 missiles each at Davis-Monthan AFB, Arizona; McConnell AFB, Kansas, and Little Rock AFB, Arkansas. In the statement of the US Secretary of Defence on the 1970-74 Defence Programme and 1970 Defence Budget, however, the following comment was made:

"Although the Titan II, with its large warhead, will still be useful against undefended large soft targets, its importance will decline greatly when large numbers of Minuteman IIIs and Poseidons enter the forces. Accordingly, we believe that after FY 1973 we can safely permit the Titan force to decline as the missiles on land continue to be used for follow-on operational reliability testing without replacement".

The general situation regarding US ICBMs has of course been modified by the SALT agreements. The most recent official US pronouncements available at the time of writing give no clear guidance regarding Titan's future, other than that there will still be 54 in the strategic alert up to mid-1975 at least. The available options would appear to be (1) to run the force down, "replacing" them by SLBM as permitted in the SALT Interim Agreement; (2) to maintain the 54-strong force by purchasing a small additional quantity to cover wastage; (3) developing a new heavy missile for the 54 silos; and (4) developing such a new missile as in (3) but increasing the number of silos by either disregarding the SALT agreement or waiting for its expiry. While (1) and (2) are probably the most and least likely courses respectively, the value of a very heavy missile in the inventory cannot be disregarded, so (3) followed by (4) could be the choice.

CHARACTERISTICS:
Designation: LCM-25C
Type: Land-based intercontinental ballistic missile
Guidance: Inertial
Propulsion: Two stage liquid propellant rocket motors. Stage 1: 195,000 kg st; Stage 2: 45,000 kg st
Warhead: Nuclear. Believed 5+ megatons
Re-entry Vehicle: General Electric Mk 6
Missile Length: Stage 1: 21.3 metres; Stage 2: 6.1 metres; Re-entry Vehicle: 4.3 metres. Total: 31.3 metres
Missile Diameter: 3 metres
Launch Weight: Stage 1: 117,000 kg; Stage 2: 29,000 kg; Re-entry Vehicle: 3,700 kg. Total 149,700 kg
Speed: More than 24,000 km/h
Ceiling: About 1,500 km
Range: About 15,000 km
MANUFACTURER:
Prime contractor was the Martin Marietta Corporation, Denver, Colorado.



Titan II launch

2707.111
TRIAD STRATEGIC DETERRENCE COMBINATION
DESCRIPTION:

Triad is the name given in the USA to the combination of its land-based, airborne and submarine strategic deterrence forces. The component parts of this combination are described in this section, in the section dealing with air-to-surface strategic missiles and in that dealing with sub-surface-to-surface weapon systems.

Details of strategic forces on alert are naturally not published by the US authorities, but an interesting pointer was given by General George S. Brown, USAF Chief of Staff, in his testimony before the US House of Representatives Armed Services Committee on the Fiscal 1975 defence budget. He said:

"The ICBM force today consists of 1,000 Minuteman and 54 Titan missiles. The alert rate of these weapons continues to be nearly 100%. The Minuteman and Titan missiles constitute over half of the megatonnage and about two-thirds of the delivery vehicles on alert to support the Single Integrated Operational Plan (SIOP), our general nuclear war plan. Minuteman III, the most modern of the ICBM force, provides weapons on alert at lower operating cost than any other Triad element."

At the time when this statement was made, the Minuteman force probably consisted of about 400 Mark III, 500 Mark II and 100 Mark I missiles which would give a total megatonnage of about 1100 MT, to which must be added between 300 and 500 MT for the 54 Titan missiles – say 1500 MT in all. The SLBM force at the same time consisted of a 656-missile mix of Poseidon, Polaris A-3 and Polaris A-2 missiles in a ratio of about 4:2:1 corresponding to an average of about 575 KT per missile or about 377 MT in all. However, only about 60% of the SSBN force is on station at any one time, so that the effective SLBM megatonnage on alert is only about 230 MT.

Interpreting General Brown's remarks on megatonnage conservatively, therefore, it seems reasonable to assume that the airborne weapon element in the strategic alert accounts for somewhere in the region of 1,000 MT.

Turning now to his remarks on delivery vehicles, it is evident that he must have been referring, so far as land-based or submarine forces are concerned, to complete missiles rather than warheads: the Minuteman/Vulcan force at the time could muster no more than 1900 warheads and the minimum number of SLBM warheads in SSBN on station must at that time have been at least 1200 and probably more like 1600; so that the land-based missiles would account for nearer one-half than two-thirds of the deliverable warheads. In terms of missiles, however, the land forces account for 1054 and the SSBN on station for about 400; so that the General's two-thirds approximation would be satisfied by adding 100-200 strategic bombers – figures which are reasonably consistent with a bomb/missile load of 1,000 MT or so. The total US intercontinental bomber inventory, however, is known to be nearly 500.

These calculations with respect to delivery vehicles are somewhat conjectural. The calculation of total megatonnage, however, is not: taking General Brown's statement at its face value it appears that the US strategic forces on alert have the capacity to deliver some 3,000 MT of thermonuclear warheads on an enemy.

THE UNION OF SOVIET SOCIALIST REPUBLICS

2900.111
INTRODUCTION

In the year that has elapsed since this introduction was written for the fifth edition, extensive changes in Russian strategic missile developments have been revealed – changes both in the numbers of different missiles that have been or are being developed and in the degree of missile system sophistication which has been attained.

From what has now been disclosed by the American authorities, it is evident that MIRV development in the Soviet Union was much further advanced – as indeed we suggested at the time that it probably was – than was generally acknowledged a year ago. MIRV tests for at least three different kinds of land-based strategic missile are now reported to have been carried out, arguing a considerable measure of confidence in the basic system design.

While our scepticism regarding the assessment of Russian progress and prospects in re-entry vehicle technology, declared by the US authorities at the time of SALT I and reiterated for some time thereafter, would appear to have been justified, however, it is important to note that the recently disclosed Russian achievements do not of themselves indicate that the American technological lead in this field has been extinguished. According to the information now available there are still no *operational* land-based strategic missiles with MIRV warheads in the Soviet Union; and even if this information should prove to be yet another understatement of the Russian achievement it is evident that the long US experience of designing and manufacturing both land-based and submarine-launched MIRV missile systems, coupled with the long and continuing programme of re-entry vehicle research and development must represent a substantial lead over their competitors. Nevertheless, since whatever barriers were previously impeding Russian MIRV advances (miniature on-board computers, probably, and possibly small but accurate inertial navigation devices) have now been breached, the Americans will have to work hard to maintain their advantage.

New Missiles

Four "new" Russian land-based strategic missiles have been described by the US authorities and assigned numbers in the US alphanumeric code. According to these descriptions, three of the missiles are significantly different from the earlier missiles; the fourth, known as the SSX-16 appears to be simply an improved version of the SS-13 (Savage) missile.

No NATO code-names for the new missiles have reached us; and because this means that there are now no such names for five of the missiles described in this section we think that readers will find it helpful if we list all the missiles in numerical order of the US code instead of alphabetically in NATO code order as before.

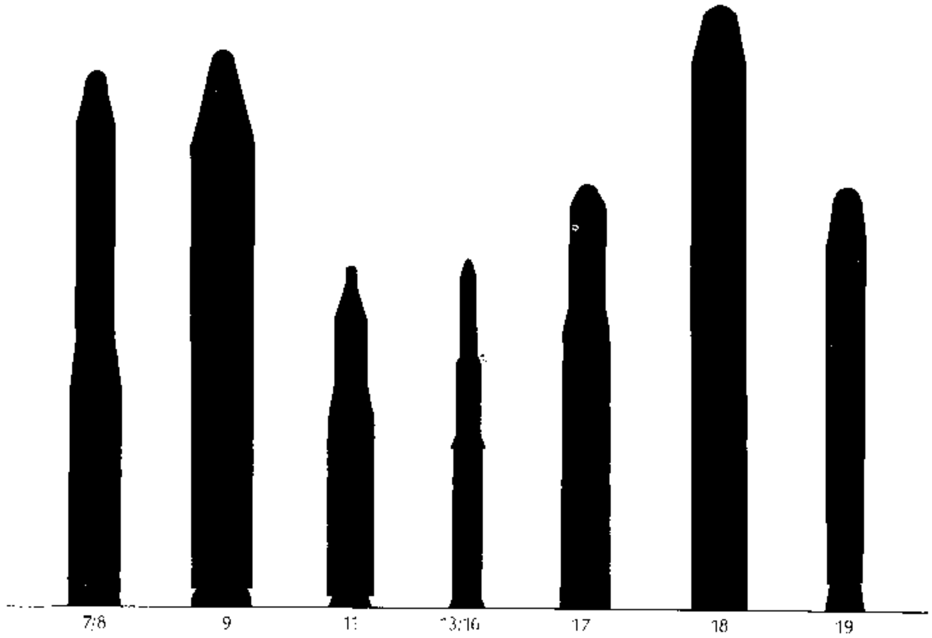
Not surprisingly, since the information on the new missiles which is available from open sources consists at best of occasional samples from what must be an extremely energetic continuing intelligence-gathering operation, inconsistencies abound; and it is not possible to give more than a general indication of the nature of the new deveiopments in the individual entries below. It is, however, instructive to compare the new range with the more important of the older missiles and an attempt at such a comparison has been made in the accompanying diagram – about which, however, the only thing that can be said with absolute confidence is that it is not accurate. It is based on a mixture of old and new information and has been simplified, not so much for the sake of clarity as for the purpose of not seeming to convey precise information on a still necessarily speculative subject. In particular, although data from American sources indicate some slight differences of size and shape between the old SS-13 and the new SSX-16 missiles we have not attempted to depict such differences here.

Older Missiles

There still remain some unresolved problems concerning the older missiles. Hardly had we consigned to the printers last year's introductory observations on the SS-11 and SS-13 missiles than we received from the USA an official document which contradicted much that we had said on the subject. This new information – together with some more recent and slightly different information – is incorporated in the accompanying diagram; and it will be seen that the SS-11 is disputed as being similar in length to the SS-13 but otherwise as quite different in shape.

However, this is not quite the end of the story. Accompanying the US Military Posture Statement for FY 1974 by Admiral Moorer (Chairman, US Joint Chiefs of Staff) was a diagram in which was shown a silhouette of the SS-7 missile as well as silhouettes of the SS-9, SS-11 and SS-13 missiles. The SS-7, which is generally associated with the NATO code-name "Saddler", was shown as a large missile only a little shorter (though significantly thinner) than the SS-9 and substantially larger than the other two. For some time, however, it has been generally accepted that "Saddler" is broadly similar to another of the older Russian ICBMs which is known as "Sasin" and usually associated with the US code SS-8.

This view received apparent confirmation in Admiral Moorer's posture statement for FY 1975, in which virtually the same four missile silhouettes were published, by a change of labelling which described the first missile as "SS-7/SS-8" – as is the first silhouette in our diagram. The problem that arises, however, is that neither in shape nor in length does the missile often seen in Moscow parades and generally identified as SS-8 or Sasin resemble this silhouette. In shape, as can be seen in the photograph accompanying entry



Silhouettes indicative of the relative sizes and general shapes of the more important operational Russian intercontinental ballistic missiles (SS-7, 8, 9, 11 & 13) and of the new generation of missiles (SSX-16, 17, 18 & 19). Silhouettes show, on the left, the SS-7 and possibly also the SS-8 (see text), the SS-9 and the SS-11; in the centre is a silhouette which is believed to be equally representative of both the SS-13 and the SSX-16; then follow the SSX-17, SSX-18 and SSX-19

2956.111 below, this missile more nearly resembles the SS-11 silhouette but it appears to be about 25% longer than that silhouette suggests.

It cannot therefore be said that the SS-11 identification problem has been satisfactorily resolved and there is now some uncertainty regarding the identification of the SS-7/SS-8 missiles. Pending receipt of further information, however, we have this year repeated the identifications which we have used before for the older missiles – except, of course, that we have brought the SS-11 description into line with the most recent data.

Deployment

If the USSR adheres to the terms of the SALT I Interim Agreement on ICBMs the maximum number of silo-launched missiles that they can deploy is 1,618. Current US estimates for mid-1974 are a total land-based static ICBM deployment of 1,587 and it is thought that, although there may be a slight increase resulting from deployment by mid-1975 of 25 SSX-18 missiles in the large silos which were under construction at the time of SALT I the total is likely to decline to a little over 1,400 by 1980, because the US authorities think that the Russians will probably exercise their option to "replace" most of their 209 old-type ICBMs by SLBMs.

Apart from these 209 missiles (SS-7 and SS-8) the remainder of the mid-1974 estimate of 1,587 is made up of 288 SS-9, 1,030 SS-11 and 60 SS-13.

Further Outlook

According to a recent US estimate, the Soviet Union may develop and test a further 12 new ICBMs, in addition to the SSX-16-19, by 1983. We report this statement because of its obvious interest and because presumably the US authorities had what seemed to them to be good reasons for making it. We find it difficult to imagine what reason the Soviet Union would have for such a lavish programme, however, and are inclined to view it with some scepticism.

2977.111
SS-3 (SHYSTER) MRBM

DESCRIPTION:

Almost certainly no longer in operational service in the USSR, although a few may still survive in relatively unimportant areas, the SS-3 missile – whose NATO code-name is believed to be Shyster – is a first-generation low medium-range ballistic missile developed in Russia from the German V-2 bombardment missile through two earlier stages known to NATO as Scunner (virtually a Russian-built copy of the V-2) and Sibling.

As can be seen in the illustration, the SS-3 exhibited a marked departure from the squat configuration of the V-2 and set the pattern for the succeeding SS-4 and SS-5 MRBMs. It is powered by a single-stage liquid-propellant rocket motor originally using LOX/alcohol fuel but subsequently converted to LOX/kerosene.

Estimates of the range of this missile exhibit wide variations – possibly because of the change of fuel.

CHARACTERISTICS:

Type: First-generation low medium-range ballistic missile
Guidance Principle: Radio command
Guidance Method: Control of guidance vanes in efflux nozzles
Propulsion: Single-stage liquid-propellant sustainer
Missile length: 21 metres
Missile diameter: 1.6 metres
Launch Weight: About 26,000 kg
Range: 800-1,200 km

STATUS:

Probably obsolete.

2952.111
SS-4 (SANDAL) MRBM

DESCRIPTION:

Known also by the NATO code-name "Sandal", the SS-4 is a low medium-range ballistic missile which is a developed version of the SS 3 (Shyster) – itself an improved version of the German V2 rocket used in the Second World War.

SS-4 was first shown in public in 1961 and became a standard MRBM in the Soviet armed forces. It was also the missile that lay at the root of the Cuban crisis in 1962: depending on the weight of the warhead the missile has a range of between 1,500 and 1,800 km, which would have enabled missiles launched from Cuba to reach the southern states of the USA.

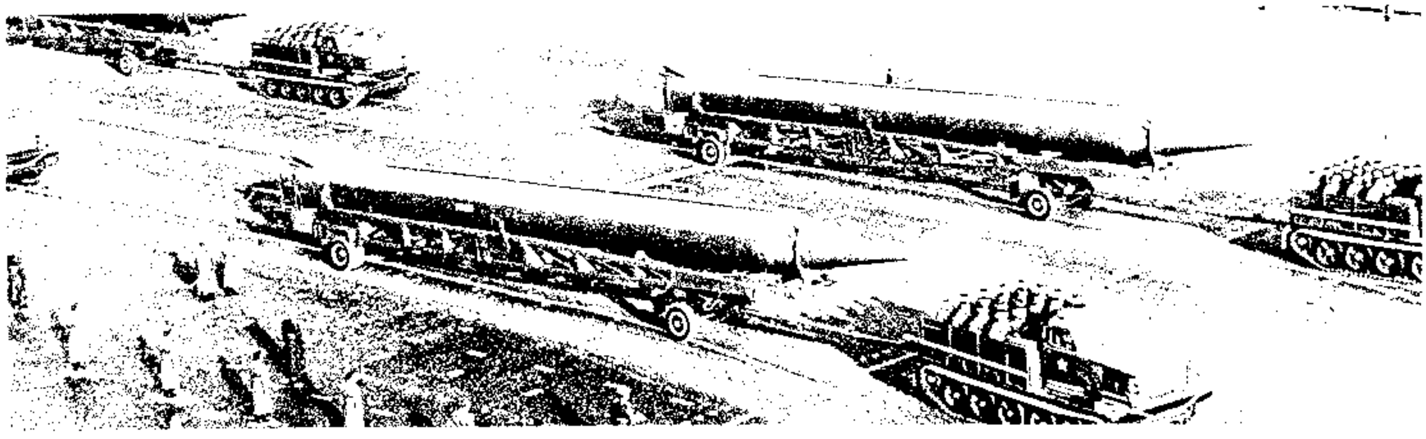
The complete weapon system comprises about twelve tractor vehicles with special trailers. Some twenty men are required to erect and launch the missile. The guidance system employed was originally radio command - operating on guidance vanes in the efflux nozzles – but it was observed at the time of the Cuban crisis that a changeover to inertial guidance had taken place.

STATUS.

SS-4 is now reported to be extensively deployed in the Central Asian region of the Soviet Union. Of some 600 MRBM and IRBM believed to be deployed in the USSR about 500 are probably SS-4s; and it is believed that a substantial number of these are targeted on installations in the People's Republic of China.

CHARACTERISTICS:

Type: Medium-range ballistic missile
Guidance Principle: Now inertial. Formerly radio command
Guidance Method: By control of elevators and of guidance vanes in efflux nozzles
Propulsion: One liquid propellant sustainer
Warhead: Optional nuclear (1 Megaton) or high-explosive
Missile Length: About 21 metres
Missile Diameter: About 160 cm
Launch Weight: About 27,000 kg
Speed at Burn-out: Mach 6 7
Range: About 1,800 km



Sandal Medium Range Ballistic Missile

2981.111
SS-5(SKEAN) IRBM

DESCRIPTION:

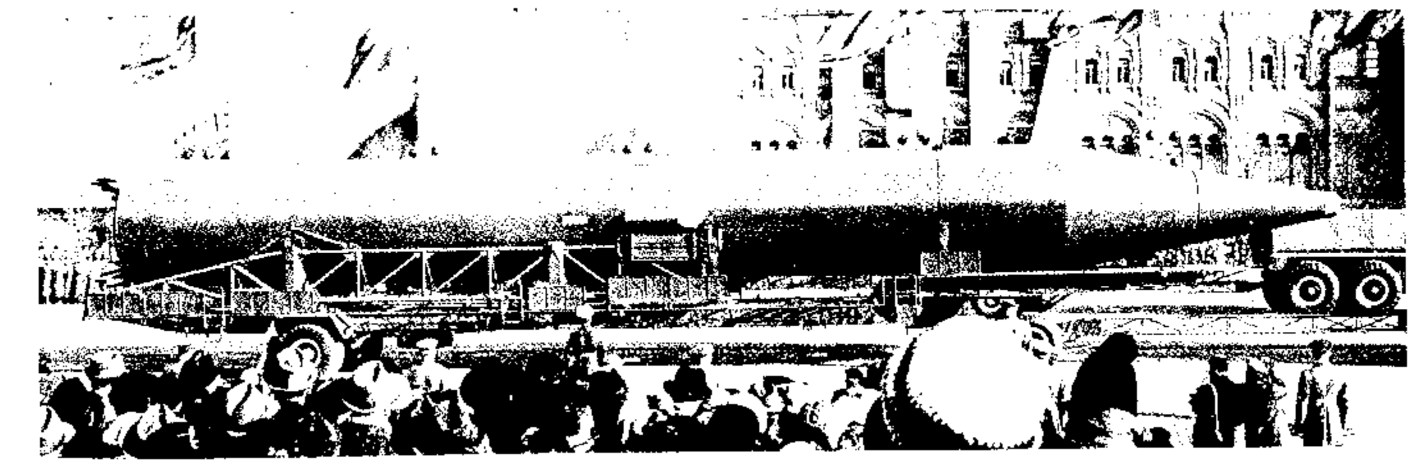
Successor to the Shyster and Sandal liquid propellant MRBM weapons, the SS-5 is an intermediate range missile also known by the NATO code-name "Skean". Although similar in general configuration to its predecessors it can be identified by the absence of tail fins and its blunted nose cone. It is carried on a different trailer, towed by the latest type of heavy tractor vehicle and has been shown inside silo underground launch facilities in official Soviet films. The missile was first displayed in 1964.

CHARACTERISTICS:

Type: Intermediate-range ballistic missile
Guidance Principle: Probably inertial
Propulsion: Single-stage liquid-propellant sustainer
Warhead: Nuclear, believed 1 MT
Missile Length: About 25 metres
Missile Diameter: About 2 4 metres
Range: Estimated 3,500 km

STATUS

Operational. About 100 of these missiles are believed to be deployed in IRBM fields.



Skean liquid propellant MRBM

2982.111
SS-7 (SADDLER) ICBM

DESCRIPTION.

SS 7, known also by the NATO code-name "Saddler" is the oldest ICBM still believed to be in the Russian operational inventory.

Despite its age, however, very little has ever been said about it in official or unofficial documents and it seems never to have found its way into any of the Moscow parades. The few references that have been made to it have almost invariably bracketed it with the SS-8 missile (**2956.111**).

As noted in entry **2900.111** above, however, the last two US Military Posture statements (for FY 1974 and 1975) have included a drawing of the SS-7 similar to the one accompanying **2900.111** which shows it to be a large missile – considerably larger than that illustrated in the SS 8 entry below – of two or possibly three stages. The data set out below summarise the generally-accepted performance data together with what can be inferred from this one published drawing.

CHARACTERISTICS:

Type: Intercontinental ballistic missile
Guidance Principle: Not known, but probably initially radio command. May have been updated to inertial
Propulsion: Probably two stages. Liquid propellant
Warhead: Nuclear, reputedly about 5 megatons
Missile Length: About 30-35 metres
Maximum Diameter: About 3 metres. Upper stage significantly less
Range: Said to be about 11,000 km

STATUS:

Operational, but obsolescent and likely to be "replaced" by SLBM under the terms of the SALT I Interim Agreement. 209 assorted SS-7 and SS-8 missiles are said to be deployed in the USSR. First deployment is said to have been as early as 1961.

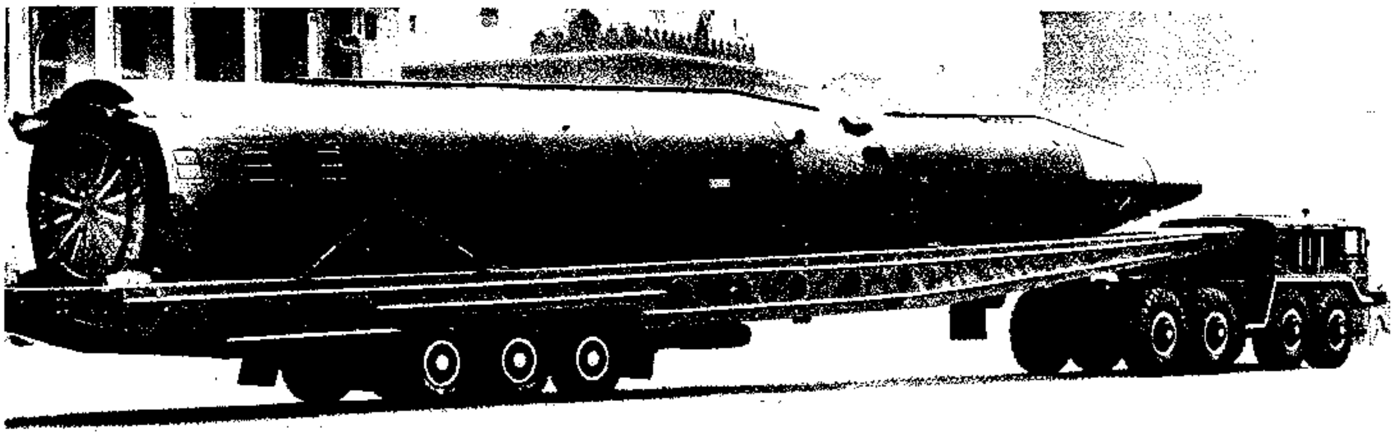
2956.111
SS-8 (SASIN) ICBM
DESCRIPTION:

Known also by the NATO code name "Sasin" the missile which has for some time been identified with the US code number SS-8 is a two-stage storable liquid-propellant long-range rocket first publicly shown in Moscow in 1964. It has not been seen in the most recent parades, but like the SS-7 (**2982.111**) it is still believed to be operational, but likely to be phased out in the fairly near future – possibly being "replaced" by SLBM in accordance with the SALT I Interim Agreement.

A little doubt has been cast on the identification of this missile (and hence on the characteristics quoted here) by the publication, in an official US document of a diagram purporting to represent both the SS-7 and SS-8 missiles (see **2900.111** and **2982.111**). Subject to this reservation, however the SS-8 appears to be some 28 metres in length, with a maximum body diameter not much under 3 metres and has an estimated range performance in the region of 10,000 km if used as a ballistic missile.

CHARACTERISTICS
Type: intercontinental ballistic missile
Guidance: Probably inertial
Propulsion: Two stage storable liquid rocket motors
Warhead: Nuclear, about 5 megatons
Missile Length: About 25 metres
Maximum Diameter: About 2.75 metres
Range: About 10,000 km
STATUS:

Operational but probably obsolescent as stated above. First deployed 1963.



Sasin liquid-propellant intercontinental missile

2962.111
SS-9 (SCARP) ICBM Mods 1 & 2
DESCRIPTION:

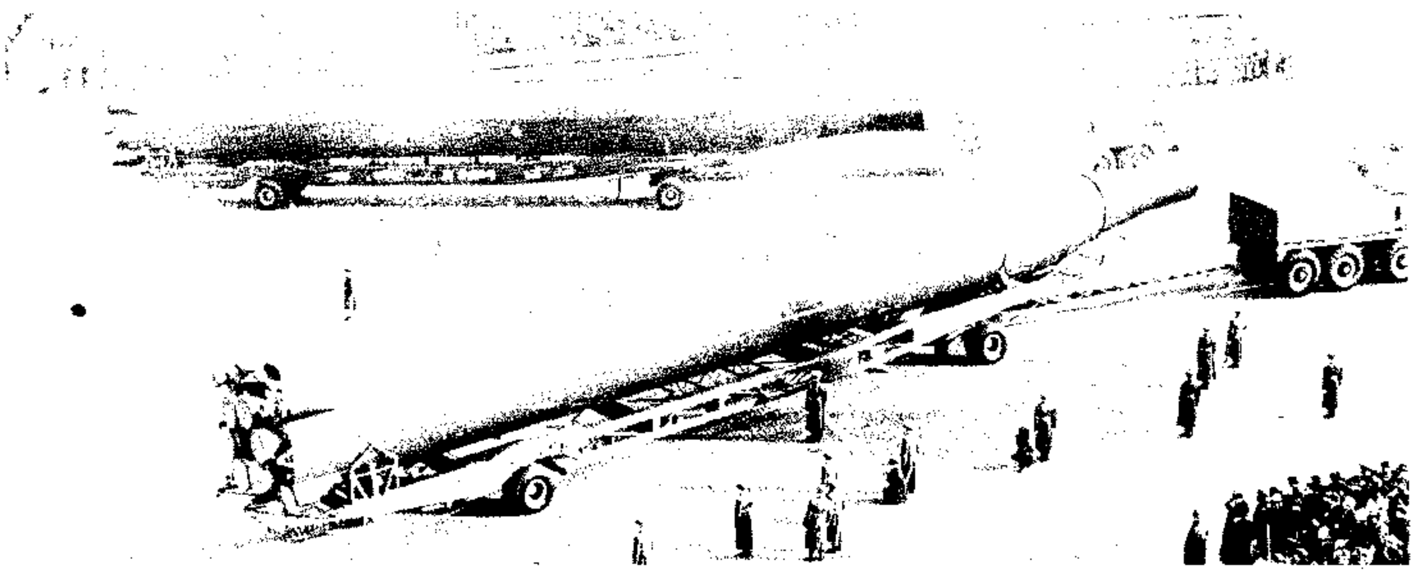
Probably the best known of all the ballistic missiles in the armoury of the USSR, the SS-9 (NATO code-name Scarp) is a three-stage liquid-propellant ICBM which was first shown in public in Moscow on 7 November 1967. The missile is some 35 metres long and 3 metres in diameter; and apart from the fact that the first stage propulsion system has six nozzles and four vernier nozzles little information is available from open sources concerning the detailed design of the weapon.

Much more is known and quite a lot has been published concerning its operational capabilities and deployment. Four significantly different versions of the missile have been identified by US intelligence and the following details apply mainly to the first two. It appears that installation started in 1965 and that by the spring of 1968 about 225 missiles had been deployed. There was then a nine-month period of apparent inactivity, after which installation was recommenced, and it is currently stated by the US authorities that there are 288 of these missiles in an operational condition.

It is believed that the rocket is capable of carrying a warhead weighing between 5,000 and 7,000 kg over a distance of some 12,000 km. In both the Mod 1 and the Mod 2 versions the payload is a single large warhead – that of the Mod 1 having a greater yield than that of the Mod 2. The larger warhead is generally believed to have a yield of 20-25 MT

CHARACTERISTICS:
Type: Intercontinental Ballistic Missile
Guidance: Inertial
Propulsion: 3-stage liquid-propellant motor
Warhead: Single nuclear warhead of 20-25 MT for Mod 1. Less for Mod 2
Missile Length: About 35 metres
Max Diameter: 3 metres
Range: 12,000 km as ballistic missile. Unlimited as FOBS
STATUS:

Operational. 288 are deployed in hardened silos. Most of these are Mod 1



The SS-9 Scarp ICBM on show in Moscow

2978.111
SS-9 Mod 3 ICBM
DESCRIPTION

SS-9 Mod 3 is the US code assigned to a version of the basic SS 9 missile (**2962.111**) which is reported to have been tested both in a depressed trajectory mode and as a Fractional Orbital Bombardment System. Some confusion regarding the meaning of these terms has been apparent in the literature and the following notes may be helpful.

Depressed Trajectory

A body moving solely under the influence of the Earth's gravitational attraction and having insufficient energy to escape from that attraction moves in an approximately elliptical (or, in special cases, circular) path. For an ICBM, assuming that all the available propulsive energy is supplied to it at the moment of launch, the trajectory will be an ellipse which intersects the circumference of the Earth at the points of launch and impact (neglecting the effects of the atmosphere). For any such pair of points there is an infinitely large number of possible elliptical trajectories but one of them is unique – the one for which the least propulsive energy is required. Looking at it in another way – for any given amount of propulsive energy there is a unique elliptical trajectory which gives the maximum range: all other trajectories, whether higher or lower than this unique trajectory will give less range from launch to impact.

It follows, therefore, that if the available propulsive energy is more than is required to transport the missile to the required destination on the minimum-energy trajectory, a set of other trajectories is available for selection by the user: the upper and lower bounds being determined by the amount of surplus energy available. It will be noted, however, that for this choice to be available the distance to be travelled by the missile must be less than its maximum range on a minimum-energy trajectory.

By selecting a trajectory which has an apogee lower than that of the minimum-energy path the missile will be better shielded from radar detection because it will cover a greater distance before appearing above the radar horizon. It will thus give the defences less time to launch an interceptor missile.

The foregoing argument is, of course, greatly simplified and neglects the complications of the effects of the atmosphere on the trajectory and the fact that the total propulsive energy cannot be supplied to an ICBM at the instant of launch. The general idea, however, should be sufficiently apparent.

SS-9 Mod 3 has, according to the US authorities, been tested in such a depressed trajectory mode – but not since 1971. It may be that now that reconnaissance satellites are so extensively used for ICBM detections the Russians feel that the sacrifice of range (or payload) is too dear a price to pay for the small advantage that may yet be gained.

FOBS

This description is misleading because, as is implicit in the foregoing discussion, the post-boost exo-atmospheric trajectory of any long-range missile is in fact a fraction of an orbit about the centre of the Earth – an orbit which would continue if the Earth's atmosphere and surface did not get in the way.

A slightly better description of what is now called FOBS would be "interrupted orbit" bombardment system; because the FOBS principle involves putting a missile into some kind of orbit (not necessarily one that is completely clear of the Earth's surface) and then – at a predetermined time – decelerating the missile so as to bring it back to the surface on a new trajectory. The principle is, of course, one that has been firmly established in space-flight programmes.

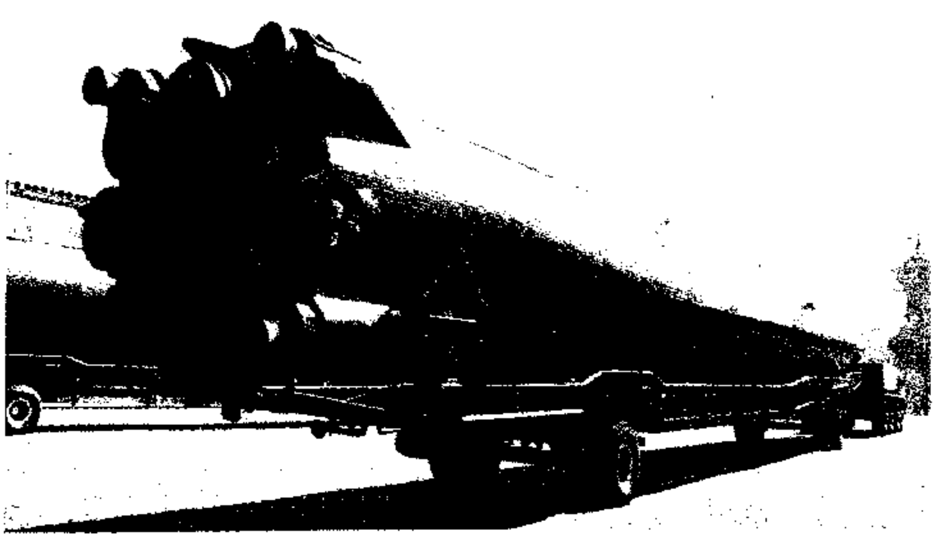
The main advantage of the technique is that, without foreknowledge of the timing and nature of the decelerations the point of impact cannot be predicted from observations of the original trajectory: predictions can only usefully be attempted when the missile is on its final trajectory, and the warning time thus available may be very short. If a full elliptical orbit can be used as the basis of the exercise an added advantage is that of being able to launch the attack from any direction.

Disadvantages are, first, that the complication of the deceleration process, possibly coupled with an exceptionally long flight, tends to reduce system accuracy unless some form of terminal guidance can be made available; and, secondly, that more energy is required to execute the FOBS sequence than is needed to put the same missile on the same target by way of a minimum energy trajectory. In practical terms this difficulty will generally be reflected in a reduction of payload.

STATUS:

According to US reports early in 1974, the SS-9 Mod 3 had not been tested for more than two years and was believed not to be deployed in any of the operational SS-9 silo complexes (presumably, since the basic missile is substantially the same as that of Mods 1 and 2, it is difficult to be sure of this).

This does not necessarily mean, however, that the depressed trajectory and FOBS techniques have been abandoned. The Russian missile development teams have obviously been very busy and the cessation of tests of the SS-9 Mod 3 may simply reflect a reduced priority for this version of the missile.



Rear view of Scarp missile, showing the six first-stage nozzles and the four verniers (Tass, 1968)

2979.111
SS-9 Mod 4 ICBM

DESCRIPTION:

This version of the SS-9 ICBM was an important element in progress towards the incorporation of MIRV systems in Russian stragetic missiles.

Tests of the SS-9 vehicle with multiple warheads certainly began at least as long ago as January, 1969 when a three-warhead MRV test over a range of some 8,000 km was observed in the USSR's Pacific testing area. Other tests were observed up to November, 1970, after which no further tests were detected for a very long time.

In the early days of these tests, because the "footprint" of the RV impact points appeared to correspond roughly with the layout of a US Minuteman complex (**2710.111**) it was thought for a time that the MRV programme had the specific objective of attacking the Minuteman force. This view was later abandoned – the "footprint" being treated as a chance coincidence – in favour of the thought that the MRV exercise was a step in the direction of a Russian MIRV system..

When testing ceased in 1970, and was not resumed in 1971 or 1972, it was deduced that the Russians had either abandoned MIRV development or at least sent the project back to the drawing board.

In January, 1973, however, a new test of what had come to be known in the USA as the SS-9 Mod 4 was detected. Once again, three RVs were carried; but these were of a new design and were equipped with parachutes for soft landing and recovery. Further Mod 4 tests were observed during 1973 and it was noted that there had been some improvement in targeting flexibility, suggesting early experiments in the MIRV technique. Up to early 1974, however, the Mod 4 system could not be classified as MIRV.

STATUS:

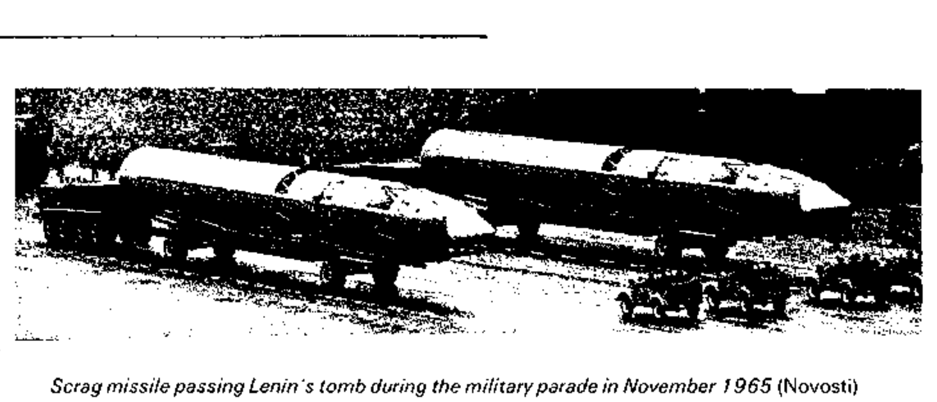
The status of the SS-9 Mod 4 is uncertain. So far as is known it is not at present deployed as an operational weapon, though presumably it could be so deployed with MRV warheads to put a number of additional heavy warheads into the Russian ICBM inventory: each of the three warheads would probably have a yield of some 4MT. Official US opinion, however, appears to be that the Russians are more likely to devote effort to their new large SSX-18 ICBM with MIRV (**2992.111**) than to continue the SS-9 Mod 4 MIRV programme up to the point of operational deployment.

2965.111
SS-10 (SCRAG) ICBM

DESCRIPTION:

Known also by the NATO code-name "Scrag" the SS-10 is a three-stage liquid propellant ICBM first shown in Moscow in 1965. It was then said to be a sister vehicle of the launch vehicle used for the Vostok and Voshkod spacecraft. The three stages are separated by truss structures with no interstage fairings.

Overall length of the missile is some 37 metres, including interstages, and the first stage base diameter is nearly 3 metres. The first stage has



Scrag missile passing Lenin's tomb during the military parade in November 1965 (Novosti) four gimballed nozzles, the second and third stages have single nozzles – that of the second being very large and that of the third quite small.

"Global range" was claimed for this weapon when it was first shown: and, having regard to its size, the published estimates of 8,000 km range seem conservative. It is believed not to be an operational weapon, but it may have been an intermediate stage in the process towards the SSX-18 missile (**2992.111**) which is the latest in the sequence of very large Russian missiles. Although the Scrag missile bears a higher number in the USA code than Scarp, the fact that the latter is evidently so successful may mean that it embodies more modern technology than does Scrag.

CHARACTERISTICS:

Type: Intercontinental Ballistic Missile

Guidance: Presumed inertial. Gimballed nozzles on first stage. Fixed nozzles on second and third stages.

Propulsion: 3-stage liquid-propellant motors

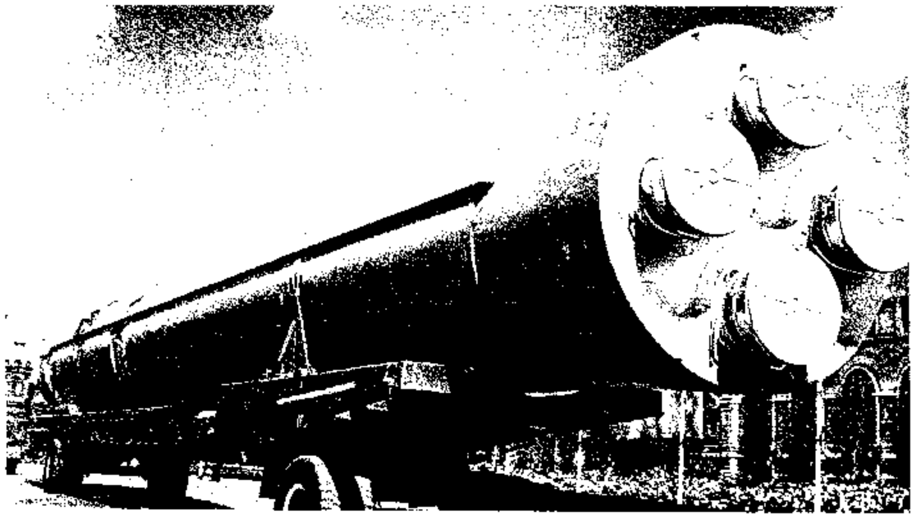
Missile Length: About 39 metres

Max Diameter: About 2.75 metres

Range: Reported as 8,000 km

STATUS:

Not operational. May have been only experimental and now abandoned.



Rear view of Scrag missile, showing the four first-stage nozzles (Tass, 1967)

2984.111

SS-11 Mod 1 ICBM

DESCRIPTION:

Currently the most widely deployed Russian ICBM, the SS-11 is believed to be a two-stage missile using storable liquid propellants and having a range of some 10,000 km. It is also believed to be of about the same length as the US Minuteman family (**2710.111**), but larger in other dimensions, and to carry a comparable payload.

None of these statements can be taken as firmly established. The SS-11 has never been identified with any of the missiles exhibited in Moscow parades (which, however, does not necessarily mean that it has never been so exhibited) nor, rather surprisingly, considering that it is supposed to have been deployed in Russia since 1966, has it been firmly associated with a NATO code-name. At various times and in various reports it has been identified with the name Savage but the general consensus appears to favour the application of this name to the SS-13 (**2958.111**) The only known positive indications of its physical appearance are two silhouette drawings published in the USA (see **2900.111** above).

According to US reports, three versions of the SS-11 have been tested and these have been numbered Mod 1, 2, 3 by the US authorities. Mod 1, to which this entry refers, is deployed in large numbers. Mod 3 is described below (**2988.111**). No definite information is available on Mod 2, other than that it is said not to have been deployed and that the US authorities believe that the programme has been terminated. Such meagre data as is available is given below for Mod 1. It has been said that the SS-11 is one of the missiles to which the new "cold-launch" technique is applicable (see **2980.111**).

CHARACTERISTICS:

Type: Silo-launched two-stage (possibly three) intercontinental ballistic missile

Guidance: Inertial

Propulsion: Storable liquid

Warhead: Single RV with nuclear warhead. Yield generally said to be 1-2 MT

Dimensions: No details known. Length appears to be about 20 m and base diameter about 2.5 m

Range: Estimates vary. Probably about 10,000 km

CEP: Said to be considerably greater than that of Minuteman

STATUS:

Large-scale operational deployment. Exact number of Mod 1 deployed is not known because a rapid Mod 3 deployment programme is reported to be in hand. It seems likely, however, that there are still 900 or more Mod 1 missiles operational. Some may be reduced-range variants targeted on China.

2988.111

SS-11 Mod 3 ICBM

DESCRIPTION:

SS-11 Mod 3 is a comparatively recently-deployed version of the SS-11 two-stage intercontinental ballistic missile which differs from the Mod 1 (**2984.111**) in the nature of its re-entry vehicle and warhead arrangements.

The Mod 3 is equipped with a multiple re-entry vehicle (MRV) arrangement of three warheads. The Mod 1 version of the missile, with its single warhead, is said by the US authorities to be considerably less accurate than the US Minuteman missiles (**2710.111** etc), and it would be expected that the addition of an MRV arrangement would reduce the system accuracy still further: the same authorities, however, give as two of the supposed reasons for the present increasing deployment of the Mod 3 "greater targeting flexibility and accuracy". It may reasonably be concluded, therefore, that the accuracy of the basic SS-11 missile system has been improved in the progression from Mod 1 to Mod 3.

Yield of the individual warheads of the MRV system is not known: but since the more complex MIRV system of the US Minuteman III missile (**2717.111**) can accommodate three 200 KT warheads it is a fair supposition that the SS-11 Mod 3 warheads have at least as great a yield as that.

CHARACTERISTICS:

Generally as for Mod 1 except for MRV warheads and improved accuracy.

STATUS:

Operational and being rapidly deployed but numbers not available. Tests were first detected by US reconnaissance in 1969.

2958.111

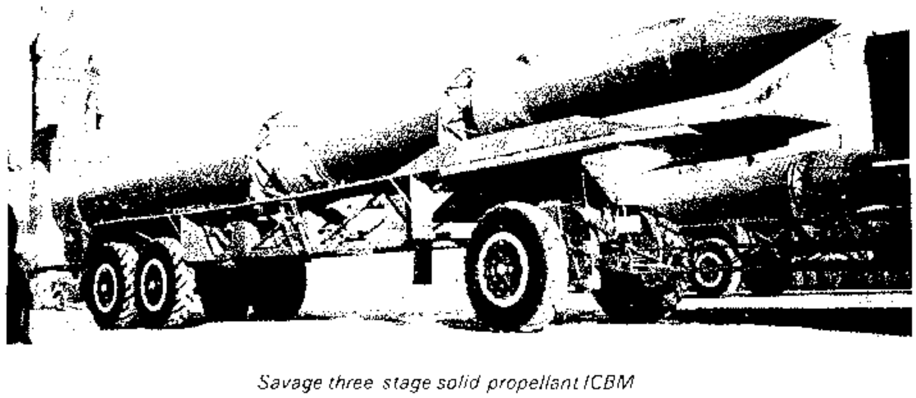
SS-13 (SAVAGE) ICBM

DESCRIPTION:

First seen in public in 1965, this missile, which may be known to NATO as Savage, is a three-stage solid-propellant ICBM that has been said to be comparable with the US Minuteman.

The three stages of the missile shown here are separated by truss structures and each has four nozzles. The two upper stages are believed to be identical with the two stages of the SS-14 Scapegoat missile (**2961.111**).

Although the missile has been in service for some time it has never been deployed statically on a large scale. So far as is known, moreover, it has never been equipped with other than a single warhead. One of the new generation of Russian strategic missiles is said to resemble the SS 13 closely and this missile (the SSX-16, **2990.111**) has also been reported to be limited at present to a single warhead.



Savage three stage solid propellant ICBM

CHARACTERISTICS:

Type: Intercontinental ballistic missile

Guidance Principle: Presumed inertial
Propulsion: 3-stage, solid-propellant motors
Warhead: Nuclear, estimated 1 MT capability
Missile Length: Over-all 20.0 metres (including interstages). 1st stage 8.7 metres. 2nd stage 4.0 metres. 3rd stage 3.5 metres. Nose cone
Missile Body Diameters: 1st stage 1.7 metres. 2nd stage 1.4 metres. 3rd stage 1.0 metre. Nose cone and re-entry vehicle 1.0 metre
Missile Base Diameters: 1st stage 2.0 metres. 2nd stage 1.9 metres. 3rd stage 1.4 metres
Range: 8,000-10,500 km

STATUS:

Operational. According to US reports 60 of these missiles have been deployed in silos. It may have been, and its top two stages are firmly believed to have been, deployed in a mobile role (see entries **2960.111** and **2967.111**).

2961.111
SS-14 (SCAPEGOAT) IRBM

DESCRIPTION:

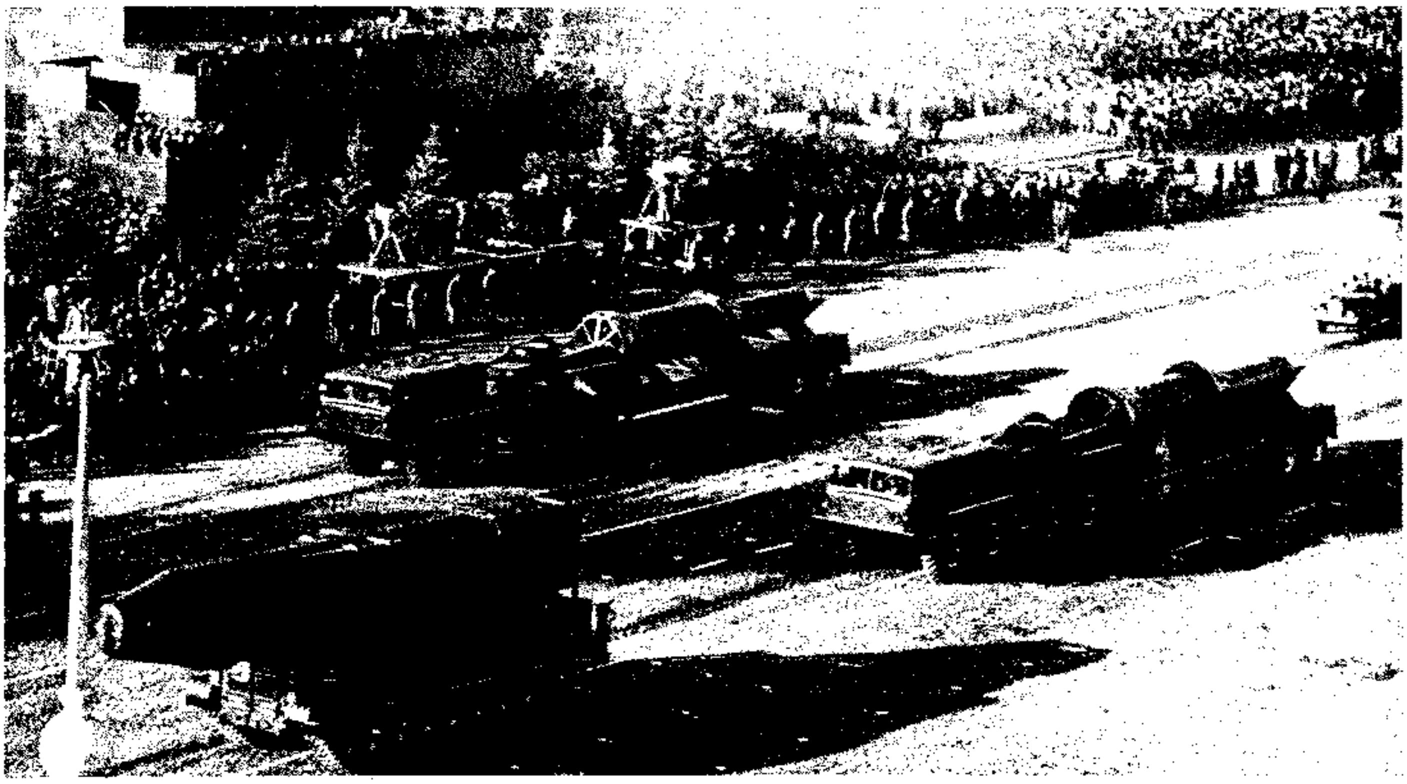
This two-stage solid-propellant IRBM appears to comprise the top two stages of the SS-13 Savage (**2958.111**) missile although the warhead section appears to be different from that of the larger missile and there may be other differences. Its length is approximately 10 metres overall. When loaded in its container and transported by its tracked erector/launch vehicle it becomes the weapon system known by the NATO code name Scamp (**2960.111**).

OPERATION:

Before firing, the missile, still in its container, is erected by the powerful hydraulic jacking system at the rear of the tracked Scamp vehicle. In the process, the cross-braced framework at the rear of the vehicle is lowered to the ground with the missile standing upright on it. The protective case is then opened to free the missile, lowered and closed again leaving the missile standing on its launching platform.

CHARACTERISTICS:

Type: Intermediate-range ballistic missile
Guidance Principle: Presumed inertial
Propulsion: 2-stage solid-propellant motors
Warhead: Nuclear That of the SS-13 missile is estimated at 1 MT but the payload of the SS-14 missile may be less and the warhead yield correspondingly smaller
Missile Length: Over-all 10.6 metres (including inter-stage). 1st stage 4.0 metres. 2nd stage 3.5 metres. Nose cone and re-entry vehicle 2.3 metres
Missile Body Diameter: 1st stage 1.4 metres. 2nd stage 1.0 metre. Nose cone and re-entry vehicle 1.0 metre
Missile Base Diameters: 1st stage 1.9 metres. 2nd stage 1.4 metres
Range: About 4,000 km



SS-14 Scapegoat missile preceded by a Scamp missile system in the 1967 parade (Novosti)

2990.111
SSX-16 ICBM

DESCRIPTION:

First of a series of four new Russian intercontinental ballistic missiles whose existence was detected by US reconnaissance during 1972 and 1973, the SSX-16 is the only one using solid propellants. A successor to the SS-13 missile (**2958.111**) it is similar in appearance – to judge by the little information that has so f · been made available – but has a greater maximum range and can carry a larger payload. Both improvements presumably result from the development of improved solid propellants.

At the time of writing the SSX-16 is reported as having been tested with only a single re-entry vehicle. Official US reports, however, say that there are indications of a Russian intention to add MIRV to this missile as has already been done for the other new missiles. It has been estimated that the SSX-16, with MIRV, could be deployed in 1975 if the programme were given a sufficiently high priority, but there is as yet no indication that this has been done.

It is also thought by the US authorities that the SSX-16 will be developed as a mobile ICBM. For such a role a mobile container of the type used for the SS-XZ (Scrooge) system (**2967.111**) would probably be used. Conceivably also the upper stages of the new missile could be used to form an improved mobile IRBM of the SS-14 Scamp/Scapegoat type (**2961.111** and **2960.111**).

CHARACTERISTICS:

Type: Intercontinental ballistic missile. Possibly mobile
Guidance: Inertial
Propulsion: 3-stage solid-propellant rocket motors
Warhead: Nuclear. Single RV with yield probably exceeding 1 MT. MIRV believed possible
Dimensions: Length about 20 m. Configuration generally similar to SS-13
Range: More than 8,000 km. Said to be more than that of SS-13

STATUS:

Advanced development. A few tests were recorded in 1972 and several more in 1973. Deployment in one form or another expected in 1975.

2991.111
SSX-17 ICBM

DESCRIPTION:

This two-stage storable liquid-propellant ICBM is one of two new Russian missiles regarded as possible successors to the widely-deployed SS-11 missile (**2984.111**). As can be seen in the illustration accompanying entry **2900.111** above both it and the other possible SS 11 successor, the SSX-19 (**2993.111**), are believed to be significantly larger than the SS-11; and this increased size is reflected in increased range and payload.

It is probable, however, that these larger missiles will be accommodated in the same basic silo as currently houses the SS-11, the additional room being provided by a change from hot to cold launching techniques (see entry **2980.111** below).

The most important aspect of these new missile developments, however, is the introduction of MIRV type warheads. Both the SSX-17 and the SSX-19 are reputed to have on-board computers and to have been tested with such warheads; furthermore, since the SSX-17 is credited with only a 4-warhead MIRV capability whereas the SSX-19 is said to be able to carry 4-6 MIRV warheads, it would seem that two different MIRV systems are involved. This lends colour to an official US view that the two missiles have been developed in competition with one another – although this seems to be a little out of keeping with normal Russian practice. Another and more recent suggestion is that one of the missiles (probably the SSX-17) is the SS-11 replacement while the other is designed for a mobile role.

CHARACTERISTICS:

Type: Intercontinental ballistic missile

Guidance: Inertial. Computer-controlled RV arrangement

Propulsion: 2-stage storable liquid-propellant rocket motors

Warhead: Nuclear. MIRV system of four warheads. Yield not known but probably not less than 200 KT each

Dimensions: No details known. Length appears to be about 24 m and base diameter about 2.5 m; but little reliance can be put on these figures

Range: Believed to be in excess of 9,000 km

STATUS:

Advanced development. Tests are said to have been observed for the first time during the second half of 1972 and there was intensive testing during 1973 and early 1974. Deployment expected some time in 1975 although recent reports have suggested that development difficulties may delay the programme.

2992.111
SSX-18 ICBM

DESCRIPTION:

Largest of the new series of Russian intercontinental ballistic missiles, the SSX-18 is said to be the functional successor to the SS-9 (**2962.111**). It is a very large two-stage liquid-propellant missile and carries a bus-type MIRV system with an on-board digital computer. This new post-boost vehicle is thought to be similar to those employed in Minuteman III and Poseidon (**2717.111** and **1133.411** and see also **2708.111**) and is believed to be capable of dispensing five to eight independently-targeted warheads. The US authorities are sure that increased accuracy has been a major consideration in the development programme, presumably with the intention of enabling the missile to attack hardened targets successfully. Some of the more recent tests, moreover, have been carried out using a single RV, from which it is deduced that the Russians may have a continuing interest in a missile with a single very powerful warhead.

The SSX-18 is somewhat larger than the SS-9 and appears to be the reason for the construction of 25 new large silos in the SS-9 fields. These silos were under construction at the time of the SALT 1 agreement and may therefore be furnished with new or additional "heavy" ballistic missiles without contravening the agreement. It has also been said that the "cold-launch" technique (**2980.111**) will be used for this missile.

CHARACTERISTICS:

Type: Intercontinental ballistic missile

Guidance: Inertial. Computer-controlled RV arrangement

Propulsion: Two-stage liquid propellant rocket motors

Warhead: Nuclear. 5-8 warhead MIRV capability. MIRV warhead yield not known but presumably in the region of 2 MT each. Single RV possible; yield again not known but presumably in excess of 25 MT. As much as 50 MT has been suggested

Dimensions: No details available. Length appears to be about 37 m and base diameter about 3 m

Range: At least 10,500 km. Probably much more

STATUS:

Advanced development. Tests were first observed at the end of 1972 and have continued at a high level ever since then. Deployment in the 25 new large silos in the SS-9 fields is expected to start in 1975; but unless the old SS-9 silos can be modified to accept the new missiles – or unless the SALT interim agreement is violated, deployment will be limited to these 25 silos.

2993.111
SSX-19 ICBM

DESCRIPTION:

Last to be detected of the four new Russian intercontinental ballistic missiles, the SSX-19 is a two-stage liquid-propellant weapon with an on-board computer and MIRV warhead system.

Believed to have been designed as a successor to the SS-11 missile (**2984.111**) it may have been developed in competition with the SSX-17 missile (**2991.111**); but another view – which does not necessarily exclude the first view – is that it is intended for use as a mobile ICBM carried in a container-launcher of the SS-XZ (Scrooge) type (see **2967.111**). Of much the same size as the SSX-17 its major difference therefrom appears to be in its MIRV system which has been said to be capable of dispensing 4-6 independently targeted warheads.

CHARACTERISTICS

Type: Silo-launched (or possibly mobile) intercontinental ballistic missile

Guidance: Inertial. Computer-controlled RV arrangement

Propulsion: Two-stage liquid propellant rocket motors

Warhead: Nuclear. MIRV system of 4-6 warheads. Yield not known but probably not much less than 200 KT each

Dimensions: Length about 20 m; base diameter about 2.5 m

Range: Believed to be in excess of 9,000 km

STATUS:

Advanced development. First tests were observed in the spring of 1973 and have continued at a fairly high rate since then. Deployment could probably begin – for the silo-launched version at least – in 1975.

2960.111
SCAMP MOBILE STRATEGIC MISSILE SYSTEM

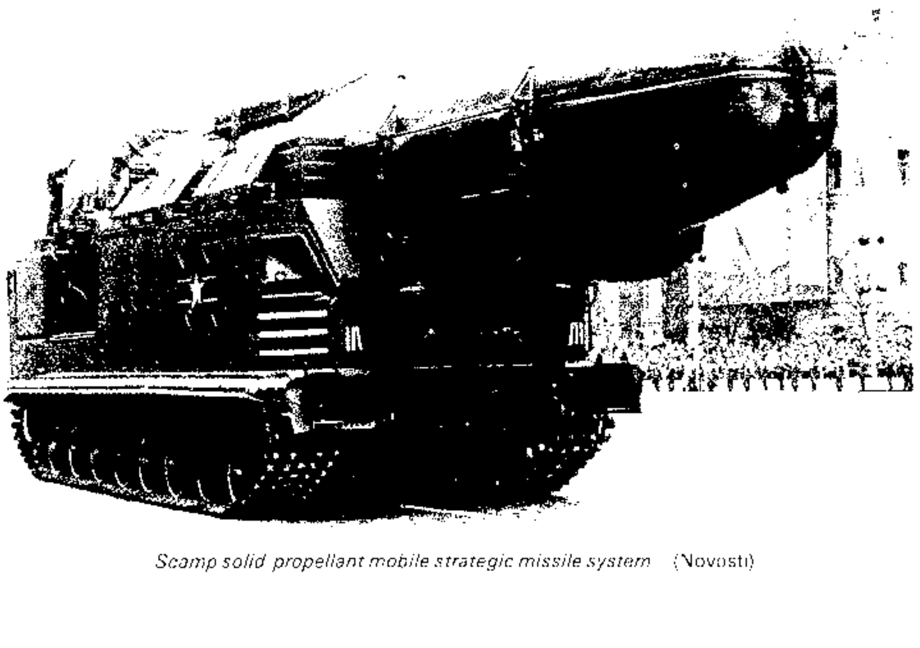
DESCRIPTION:

This NATO code-name is applied to a complete weapon system comprising the SS-14 Scapegoat missile and its associated erector/launcher. It was first seen in public in 1965, the missile itself then being enclosed in an all-concealing container – nicknamed the "Iron Maiden".

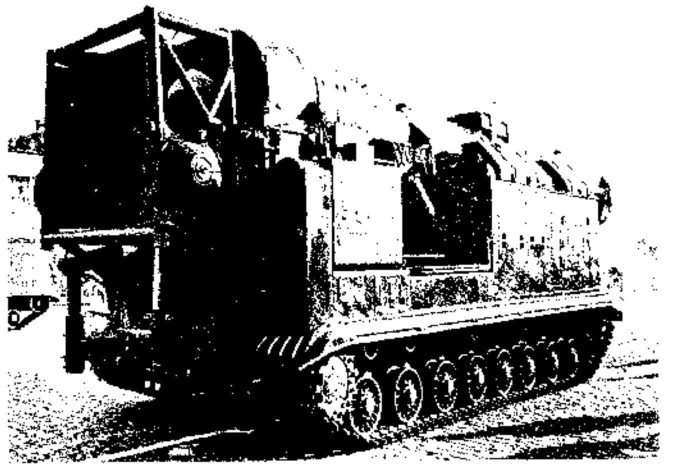
It was then learned that the missile inside was that now given the NATO name Scapegoat (**2961.111**), which was publicly shown without its container in 1967.

The role of the weapon appears to be that of a mobile strategic missile – constantly changing its firing position and always ready for action.

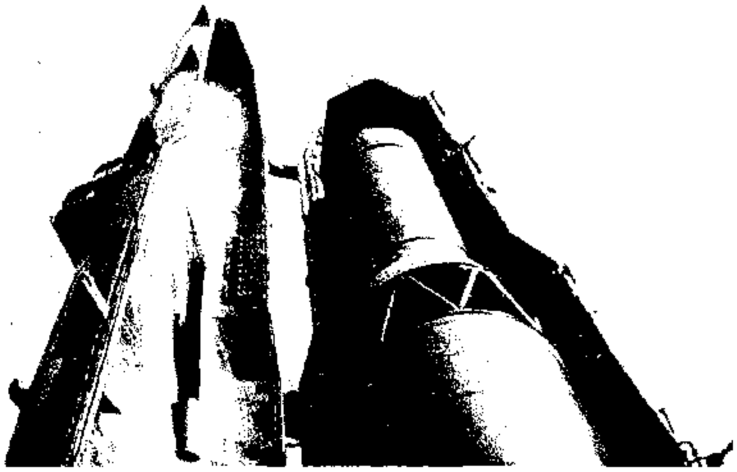
The chassis of the erector/launcher is the JS III which is also used for transporting missiles.



Scamp solid propellant mobile strategic missile system (Novosti)



Rear view of the Scamp missile system at a Moscow parade in 1966 (Novosti)



Scapegoat missile in place within the container of its Scamp transporters launch vehicle

2967.111
SS-XZ (SCROOGE) MOBILE STRATEGIC WEAPON SYSTEM

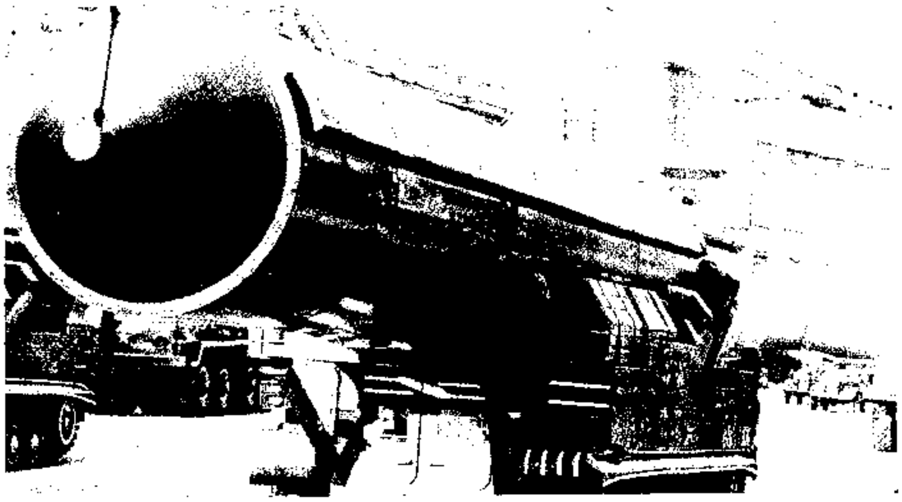
DESCRIPTION:

Scrooge is the NATO code name for a strategic missile which, like Scamp (**2960.111**), is carried in a container on a tracked transporter/erector/launch vehicle. Unlike the Scamp container which is hinged to open up (hence its nickname) the Scrooge container is tubular and is assumed to be used to launch the missile. The tracked vehicle that carries the missile is basically the same as that used to transport Scamp. The missile system is usually referred to in the USA as SS-XZ.

Scrooge is longer than Scamp and therefore presumably is intended to carry a longer-range missile. The launcher tube is some 20 metres long and 2 metres in diameter.

Until recently Scrooge was not believed to be an operational system. It now seems, however, that it is: it has been reported as being deployed near the Chinese frontier in Outer Mongolia.

There remains the question of the missile inside the container. Clearly it has to be a fairly thin one: which suggests that it probably uses solid propellants and, on the assumption that the Russians are more likely to have adapted an existing missile than to have developed a new one, we think it likely that another version of the SS-13 – possibly with a less powerful first stage – is used. This is, however, no more than an informed guess.



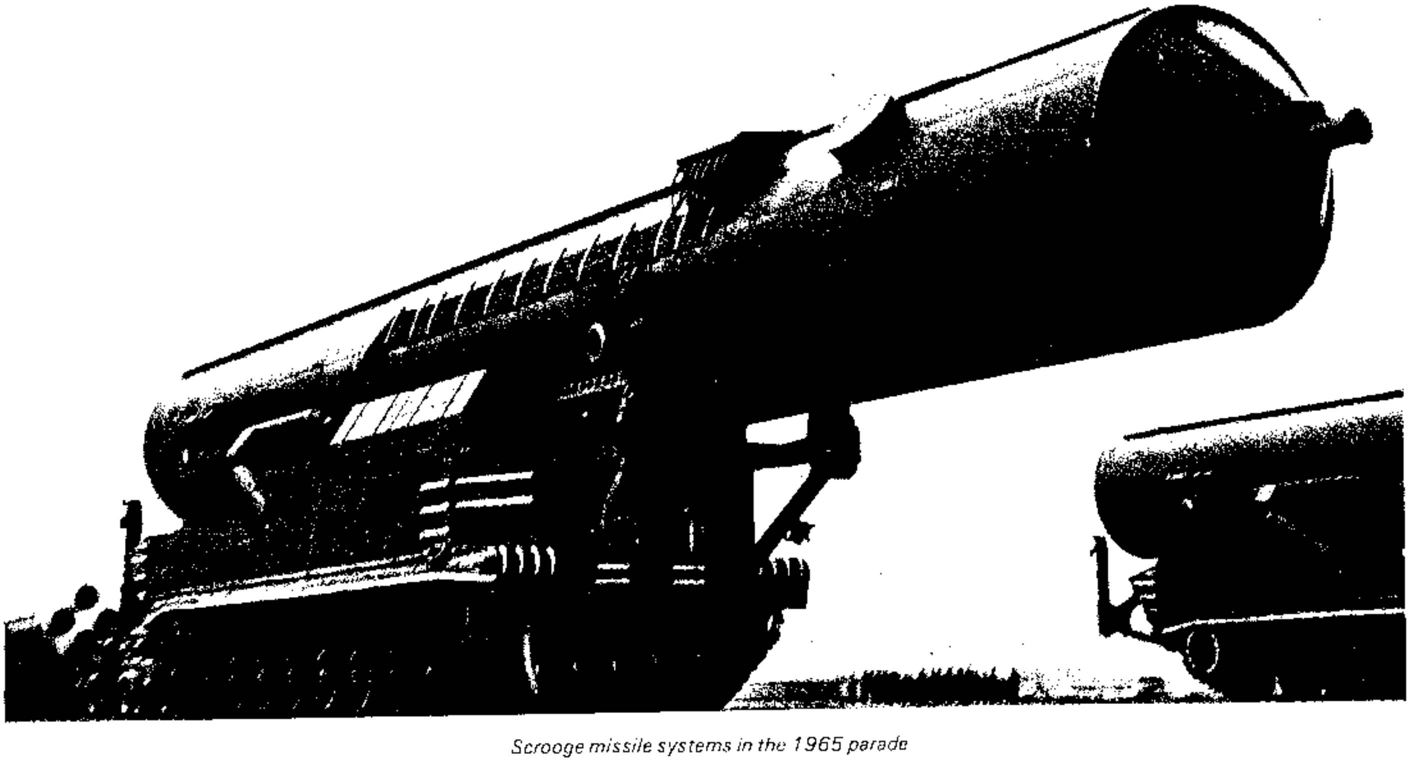
Scrooge mobile ballistic system (Tass)

CHARACTERISTICS:

Type: Mobile ballistic missile system
Guidance: Presumed inertial
Propulsion: Probably solid propellant, two or three stages
Warhead: Not known but could be 1 MT
Launcher Length: About 20 metres
Launcher Diameter: About 2 metres
Range: Uncertain. A minimum of 5,000 km seems reasonable and it could be much more

STATUS:

Operational as noted above. A recent press report from the USA has suggested that the SSX-19 missile (**2993.111**) may be used in the system, but on the information so far to hand this would appear to be impossible. The SSX-16 (**2990.111**), however, could well be a candidate.



Scrooge missile systems in the 1965 parade

2980.111
COLD-LAUNCHED BALLISTIC MISSILES
DESCRIPTION:

A feature of the 1973 November parade in Moscow was the first appearance of "cold-launch" canisters for ballistic missiles (a picture of these canisters is published on the first page of this strategic missile section in entry (**2200.111**).

There is nothing new in the idea of "cold launching" – a technique whereby a missile is ejected from its silo or launch tube by compressed air or by some other kind of gas generator instead of by the thrust of the main rocket motors since it has been used for SLBM launches by the concerned countries for some time. Its application to ICBM launches is novel, however, and has a number of advantages.

First, because the cold gas ejection is much less destructive than the hot efflux of an ICBM first-stage motor and because the technique delays the ignition of this motor until after the missile has cleared the silo, far less protection is required for vulnerable apparatus within the silo, furthermore, when the first-stage motor is used for ejection the operation is one of rocket thrust, not pressure ejection, so that adequate venting must be provided both below and around the missile but still within the protective shield. This means that the silo must be both deeper and much wider than the missile: with the cold-launch technique a much larger missile can be accommodated in a given silo.

Secondly, by developing container launcher tubes for each missile many of the difficulties of adapting old silos to new missiles are overcome.

Thirdly the use of these container-launchers simplifies the operation of reloading silos and enables missiles to be stored conveniently.

STATUS:

The container launchers exhibited in 1973 have been variously reported for use with the SS 11 (**2984.111**) and SSX 17 (**2991.111**) missiles. They are almost certainly too small for the latter missile but might be large enough for the former. In any case the canisters shown were probably experimental models.

It seems likely, however, that the Russians will proceed with this programme and deploy cold launched missiles even if they have not already done so.

TACTICAL SURFACE-TO-SURFACE MISSILES

2283.111
INTRODUCTION

This section deals with land-based or shipborne tactical systems whose primary function is to attack surface targets. All entries in the section relate to *guided* weapons. information on guns and barrage rockets – for use by land or naval forces – and on *unguided* weapons otherwise similar to those described in this section will be found in Section Three.

For convenience of study and reference, the weapons have been divided into four groups and are listed in alphabetical order of country of origin within these groups. The groups are:

Anti-tank/Assault Weapons
Battlefield Support Weapons
Coastal Defence Weapons
Shipborne Weapons

ANTI-TANK/ASSAULT WEAPONS

2284.111
INTRODUCTION
Guided Line-of-Sight Systems

Most of the weapon systems described in this sub-section are small (up to 75 kg but mostly much less), optically-aimed, guided missiles designed primarily to disable enemy armoured fighting vehicles but usually suitable also for attacking fortified portions. They range in size from systems which are sufficiently small and light to be carried complete by one man to crew-served systems which are suitable only for installation in a substantial vehicle. Many of the systems can be adapted for use in light aircraft and helicopters, and entries dealing with such applications will be found in the sub-section dealing with air-to-surface weapon systems. A few systems have also been adapted for naval use.

Reference is frequently made to various "generations" of such weapon systems. Usage in this respect is not firmly established, but the following rough definitions may be helpful.

First Generation. A weapon system in which the operator observes both missile and target and manually guides the one towards the other. Guidance in such systems is effected by the transmission of electrical guidance signals from the operator's control unit along a pair of thin wires reeled out from the missile as it flies towards the target.

Second Generation. A system in which the operator observes the target and keeps his sight trained on it. The missile is tracked automatically and the displacement between it and the operator's line of sight is used to generate guidance commands which are conveyed to the missile either by means of trailing wires or, as in the American Shillelagh system (**2809.111**) by some other form of command link.

Third Generation. A system in which, as in a second-generation system, the operator has only to keep his sight trained on the target but in which the deviation of the missile track from the sight-line (defined, for example, by a coded laser beam) is measured by apparatus which is carried by the missile and which generates appropriate guidance commands and applies them directly to the missile guidance system.

Other Guided Systems

One quite different anti-tank system is described in this sub-section: this is the terminally-guided sub-missile system (**2838.111**) being developed in the USA.

Other Anti-tank/Assault Weapons

Information on unguided anti-tank missiles, recoilless anti-tank weapons and anti-tank guns will be found in Section Three. Information on tanks and other armoured fighting vehicles having anti-tank roles will be found in Section Two

BRAZIL

2025.111
ANTI-TANK MISSILE

The Brazilian Army's Central Missile Commission has for some time been reported to be developing a wire-guided anti-tank missile which will have a range of approximately 3 km. Nothing has been heard of this project recently, however, and while it seems unlikely that it has been cancelled it is not definitely known to be in progress.

What is known, however, is that Brazil was one of the four countries to which production licences were issued for the German (MBB) Cobra wire-guided anti-tank missile (**2181.111**). It is possible that there has been some confusion here – although the range of Cobra is less than 3 km.

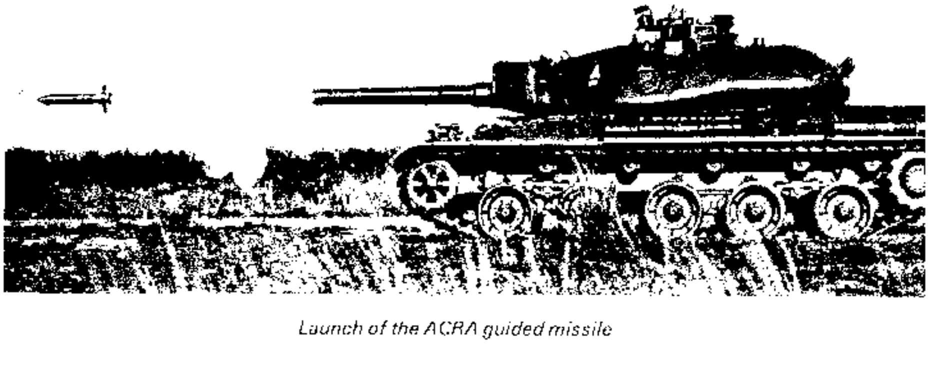
Comissao Central de Misseis

FRANCE

2071.111
ACRA ANTI-TANK WEAPON SYSTEM
DESCRIPTION:

ACRA (Anti Char RApide) is the acronym devised for the third generation anti-tank weapon system developed by the Groupement Industriel des Armements Terrestres (GIAT) at l'Atelier de Construction de Puteaux.

Two separate weapons are employed in the system, one a guided missile and the other an unguided rocket, both of which are gun launched. The guided missile is cylindrical in shape and has four narrow chord flip out folding tail fins for guidance and four small anti-roll fins for stabilisation. When assembled into its cartridge case (see picture) the complete round has an over all length of 1.25 metres. The calibre is 142 mm. The cartridge case is automatically ejected on launch.



Launch of the ACRA guided missile

OPERATION:
The gun launch gives the missile a high initial velocity of 150 m/sec as it leaves the muzzle whereafter its sustainer rocket enables it to achieve a cruising speed of some 970 knots (1,800 km/h), the time of flight to 3 km being less than 7 seconds. Infra-red guidance is used: the missile being guided along a director beam emitted by a laser.

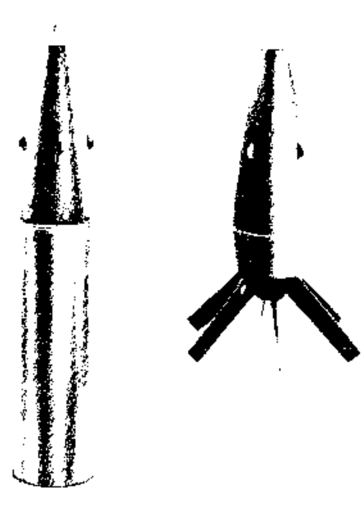
As an alternative to the missile, an unguided rocket-assisted spin-stabilised projectile can be fired from the same gun-launcher against soft targets. This projectile is smaller than the guided missile but is of the same calibre. The gun-launcher imparts an initial velocity of 1,070 knots (1,980 km/h); and immediately on leaving the nozzle the projectile's own propulsion charge boosts the speed to 1,360 knots (2,520 km/h). At the same time six folding fins in the base of the projectile open out to stabilise the projectile in flight.

LASER GUIDANCE:
Ground equipment of the TRT laser guidance sub-system comprises four small packages plus vehicle installed cooling systems equipped with ion exchangers. One package contains the laser emitter, working on a wavelength of 1.06 microns and having an output power in excess of 5W, the beam modulation devices, the laser crystal cooling system and the tube starting device. A second package contains the supplies for the laser pump and a third the sequencing and servo equipment. The fourth contains the pumps for the laser emitter cooling liquid.

The laser beam modulation is coded in such a way as to enable the missile to determine its position relative to the beam axis. In essence this is an angular determination, but a zoom lens is used to provide a guidance field of substantially constant diameter and to offset the tendency of the guidance error to increase with missile distance from the gun launcher.

Infra-red guidance equipment on the missile consists of three sub-assemblies. On the base of the missile is an array of four symmetrically disposed tubes containing photodiodes sensitive to 1.06 micron radiation and signals from these are passed to a 2AP7 (TRT) input system which includes a pre-amplifier and two limiters. The third unit is the 2T7 receiver which contains the azimuth and elevation data decoding and processing circuits, the outputs from which are used to control the flight of the missile. Weight of these three units is 1.05 kg and current consumption is 150 mA at −29V and 250 mA at +29V.

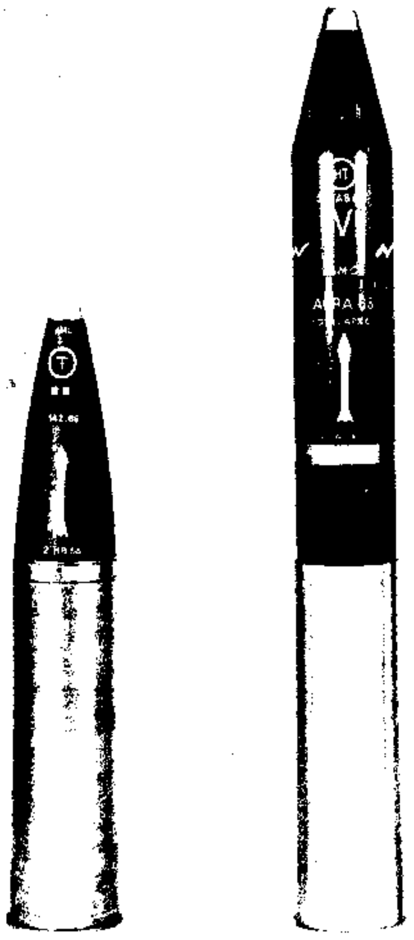
CHARACTERISTICS:
Type: Semi-automatic gun-launched heavy anti-tank guided weapon system
Guidance Principle: Infra-red beam-riding



The unguided projectile of the ACRA system showing the flip-out tail fins

Guidance Method: Control of missile tail surfaces
Warhead: Shaped charge
Calibre: 142 mm
Length of Round: 1.25 metres
Weight of Round: 26 kg
Speed: 500 m/sec
Range: From 25 m to at least 3,800 m
Time of Flight: Less than 7 sec to 3 km
Unguided Projectile:
Type: Fin-stabilised gun-launched missile with folding fin stabilisers and additional propulsion operating on departure from muzzle
Warhead: Choice of steel (2 kg RDX-TNT) anti-vehicle or cast iron (2 kg TNT) anti-personnel
Length: 90 cm with cartridge, 64 cm missile alone
Weight: 21 kg with cartridge, 15 kg missile alone
Muzzle Velocity: 550 m/s
Velocity at 1 km: 700 m/s
STATUS:
More than 500 missiles have been fired in trials during the development programme which terminates at the end of 1974.

During these trials, it is understood, the guidance system proved to be 100% effective from minimum range out to more than 3,800 metres. The effectiveness of the system against both stationary and moving targets was demonstrated as also was the possibility of engaging targets while on the move.



The unguided and guided weapons of the ACRA system

Nevertheless no financial provision is being made at present for putting the system into production.

MANUFACTURERS:
System:
Groupement Industriel des Armements Terrestres, 10 place Georges Clémenceau, 92211-Saint-Cloud, France
Unguided Projectile:
Compagnie Francaise Thomson Houston – Hotchkiss Brandt, 52 Avenue des Champs Elysées, Paris 8e, France.
Laser Guidance:

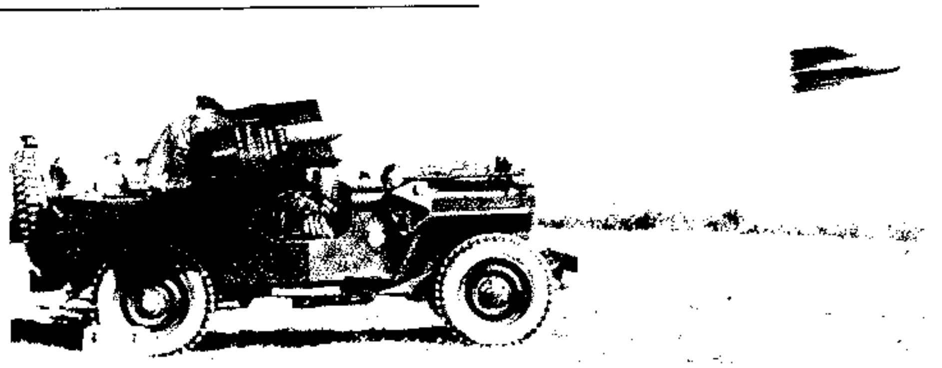
2081.111
ENTAC ANTI-TANK MISSILE

DESCRIPTION:
Entac is a first-generation, roll-stabilised, wire-guided, anti-tank weapon intended primarily for infantry use. The name is a contraction of Engin Téléguidé Anti-Char.

The complete weapon system comprises a fire-controller, a four-missile launcher, a Jeep or other carrier, check-out and test equipment and missiles. The missile is supplied complete in a polyester water-tight container.

OPERATION:
As with other first-generation wire-guided missiles, the operator uses an optical sight to locate and track the target and a manual control to command the missile to his line of sight. Remote control up to a maximum operator-missile separation of 110 metres is possible. A single operator can manage a firing post and control 10 missiles.

CHARACTERISTICS:
Type: Surface-to-surface, wire-guided anti-tank weapon system
Guidance Principle: Command to line-of-sight
Guidance Method: Optical sighting and manual remote control of missile



Entac anti-tank missile leaving its container-launcher

Propulsion: Two-stage solid-propellant rocket motor
Warhead: Shaped charge 4 kg
Missile Length: 82 cm
Missile Diameter: 15 cm
Launch weight: 12.2 kg
Maximum Speed: 305 km/h
Range: 400-2,000 metres
Armour Penetration: 650 mm
HISTORY:
Entac was developed by the Direction Technique des Armements Terrestres (DTAT) and is produced in quantity by Aérospatiale. In its Model 58 form it was adopted by the French Army in 1957 and is now standard equipment also in the armies of Australia, Belgium, Canada, Indonesia, the USA and other countries. Well over 130,000 missiles have been delivered.

MANUFACTURER:
Société Nationale Industrielle Aérospatiale, Division des Engines Tactiques, 2à18 rue Béranger, 92320-Châtillon-sous-Bagneux, France.

Launch of Harpon ground-to-ground missile

2095.111
HARPON BATTLEFIELD MISSILE

DESCRIPTION:

Harpon is a wire-guided battlefield weapon system intended for use on land vehicles, ships, fixed wing aircraft and helicopters. Manufactured by Aérospatiale, it has the same characteristics, performance and alternative warheads as the SS 11 B1 weapon (**2139.111**) also made by Aérospatiale, but has a greatly improved and automatic form of guidance.

CHARACTERISTICS:

Type: Surface-to surface (or air-to-surface) guided weapon for anti-tank or other battlefield roles
Guidance Principle: Automatic command to line-of-sight
Guidance Method: Optical target tracking. Automatic wire-guidance control of missile by varying thrust of sustainer efflux
Propulsion: Two-stage solid-propellant rocket motor
Warhead: Various (as SS 11 B1)
Missile Length: 121.5 cm
Missile Diameter: 16 4 cm
Wing Span: 50 cm
Launch Weight: 30 4 kg
Cruising Speed: 360-384 km/h
Minimum turning:
Radius: 1 km
Range: 400-3,000 metres
Armour Penetration: 600 mm

OPERATION:

With the improved TCA (Télécommande Automatique) guidance system incorporated in the Harpon system all that the operator has to do is to aim carefully at the target through his optical sighting device. Infra-red radiation from flares on the rear of the missile is detected by a precision goniometer so mounted that its reference axis is accurately parallel to the optical axis of the operator's sight. The angular deviation of the missile from line-of-sight thus measured, coupled with the estimated distance travelled by the missiles provide a measure of the missile's departure from the required track. This measurement is used in the computation of the signals that are transmitted over the trailing wires to correct the missile's course. This guidance system, it is claimed, will maintain the missile's flight within 1 metre of the instantaneous line of sight.

STATUS:

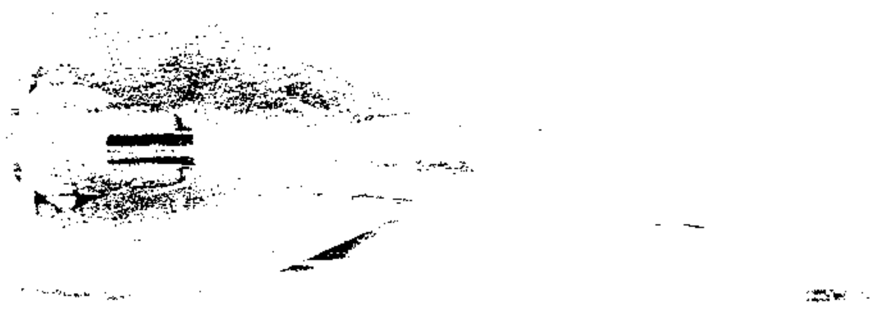
In production.

Four-round Harpon system on an AMX-13 tank

MANUFACTURER:

Société Nationale Industrelle Aérospatiale, Division des Engins Tactiques, 2à18 rue Béranger, 92320 - Châtillon - sous - Bagneux, France.

2139.111
SS 11 BATTLEFIELD MISSILE



SS II Missile

DESCRIPTION:

SS 11 is a line-of-sight wire-guided battlefield missile intended for firing from land vehicles, naval vessels and slow-moving aircraft. Normally fired from a launching ramp it may also be used with a simplified ground launcher. The designation SS 11 is applied to the surface-to-surface version; the generally similar air-to-surface version is known as the AS 11 (**1173.311**).

OPERATION:

The operator acquires the target by means of a magnifying optical device. As soon as the missile enters his field of vision after launch, the operator commands it to his line of sight by means of a joystick. The signals are transmitted over wires trailed from the missile. Tracer flares are installed on the rear of the missile for visual reference.

When installed in a helicopter or ship the simple sighting device used for land vehicles is replaced by a special stabilised sight.

CHARACTERISTICS:

Type: Surface-to-surface tactical guided missile
Guidance Principle: Command to line-of-sight
Guidance Method: Optical tracking and manual wire-guided remote control of missile by vectoring the thrust of sustainer efflux (T.V.C.)
Propulsion: Two-stage solid-propellant rockets motor
Warhead: Various (see text)
Missile Length: 120 cm
Missile Diameter: 16.4 cm
Span: 50 cm
Launch Weight: 29.9 kg
Average cruising speed: 360-584 km/h
Minimum turning radius: 1 km
Range: 500-3,000 metres
Armour Penetration (140AC warhead): 600 mm

SS 11 B1

Since 1962, the SS 11 B1 version, using transistorised firing equipment, has been in production. It is available with a variety of different warheads, including an inert type for practice, the Type 140AC anti-tank warhead capable of perforating 60 cm of armour plate, the Type 140 AP02 explosive warhead (2.6 kg of explosive) which will penetrate an armoured steel plate 1 cm thick at a range of 3,000 metres and explode about 2.1 metres behind the point of impact, and the Type 140 AP59 high-fragmentation anti-personnel type with contact fuse

Some 153,000 of the SS 11 series of missiles have been delivered – including both ground and airborne versions and including also the Harpon (**2095.111**) version – to more than twenty customer countries.

MANUFACTURER:

Société Nationale Industrielle Aérospatiale, Division des Engines Tactiques, 2à18 rue Béranger, 92320-Châtillon-sous-Bagneux, France.

2140.111
SS 12 BATTLEFIELD MISSILE

DESCRIPTION:

The SS 12 is a spin-stabilised, wire-guided surface-to-surface missile system derived from the Nord SS 11 The AS 12 is the air-to-surface equivalent.

Principal change in the missile is the incorporation of a much larger warhead – with consequent changes in the propulsion equipment – which makes the weapon effective against fortifications as well as tanks, ships and other vehicles. Available warheads include the type OP.3C which can pierce more than 40 mm of armour and explode on the other side.

The guidance system for the SS 12 is the same as that developed for the SS 11 and described under the entry for that weapon system (**2139.111**) in this section.

CHARACTERISTICS.

Type: Surface to surface tactical guiden weapon
Guidance Principle: Command to line of-sight
Guidance Method: Optical target tracking. Manual infra-red tracking of missile and wire-guided remote control by vectoring the thrust of sustainer efflux
Propulsion: Two-stage solid propellant rocket motor
Warhead: 30 kg HE
Missile Length: 187 cm
Body Diameter: 18 cm
Warhead Diameter: 21 cm
Span: 65 cm
Launch Weight: 75 kg
Range: 6,000 metres
Time of Flight: 32 sec
Average Speed: 190 m/s
Maximum Speed: 260 m/s

MANUFACTURER

Société Nationale Industrelle Aérospatiale, Division des Engines Tactiques, 2à18 rue Béranger, 92320 Châtillon-sous-Bagneux, France.

GERMANY (FEDERAL REPUBLIC)

2181.111
COBRA 2000 ANTI-TANK MISSILE

DESCRIPTION:

This weapon system – full designation BO 810 Cobra 2000 – comprises a small wire-guided anti-tank missile, a control box and cable links. It is a lightweight low-cost weapon suitable for operation by one man, who can readily carry, set up and fire two missiles.

OPERATION.

Unlike many other wire-guided missiles, Cobra is not launched from a container; the missile is simply set down on the ground and, when it is fired, a booster mounted on the underside gives it a jump start that lifts it clear of even rough ground before the sustainer develops full power.

Before launching the missile is connected to the control box by a cable. This control box contains a battery that supplies the power required to launch and control the missile and, once connected, the missile can be launched simply by pressing the launch button. By means of a junction box up to eight missiles can be connected simultaneously to the control box on which is mounted a selector switch that enables the operator to fire and control these missiles one at a time.

A target coincidence guidance technique is used. The operator has a joystick control which enables him to give lateral and vertical commands to the missile through the guidance wire trailed out behind it. Immediately after launch the missile has to be gathered rapidly into the operator's line of sight to the target and quite substantial movements of the joystick may be necessary to achieve this thereafter relatively small movements should suffice to keep the missile framed in the target. Tail-mounted flares make it easy for the operator to see the missile in flight.

An electrical testing device built into the control unit enables the controller to carry out a pre-launch check.

The cable attached to the missile is 20 metres long and that attached to the junction box is 50 metres long. The operator can thus position himself conveniently up to either 20 or 70 metres from any one missile.

DETAILED DESCRIPTION:

In the following description the figures in parentheses refer to the identification numbers on the accompanying cutaway drawing. The warhead (1) is an armour-piercing hollow-charge head, capable of destroying all types of tanks. A dummy head is substituted when the missile is used for training purposes.

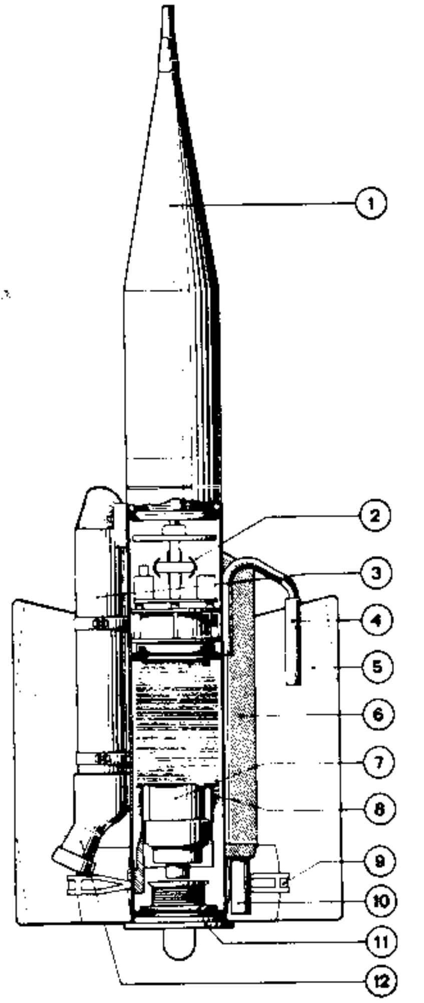
An adapter ring located at the front part of the missile permits rapid insertion and locking of the warhead to the missile. Four plastic wings (5) located 90° apart are fitted to the outside of the missile fuselage. Each wing has a spoiler assembly (9) which acts as an aileron to steer the missile and is protected by a cover against dust and water during transportation. A carrying handle (4) is located between the two upper wings. Directly behind the handle are the battery (6) and the two colour flare assembly (10). The booster rocket (3), used for launching, is located between the two lower wings.

The receiver-gyro assembly (2) is mounted directly behind the warhead adapter ring. The principal function of the receiver-gyro assembly is for stabilisation of the missile. It is fastened to the main fuselage tube, which contains the spar element that houses the sustainer rocket assembly (7). The spool assembly tube (8) containing the 2,050 m (2,240 yards) of guidance wire is fastened to the same spar. The rear end of the fuselage is protected by a removable cover lid (11) which also serves as water seal prior to launching and contains the 2-m (6.6 ft) launching cable with hook. Before launching the missile, the cable is fastened to an anchor peg by a snap hook. When pulling off the cover lid, the protection covers for the spoilers are automatically released.

Two solid-fuel rocket motors are used for propulsion. The nozzle of the booster motor (12) is curved and directed towards the ground, causing the initial flight to be at an angle of 20° to the ground. The missile can be launched from any surface without special devices.

Cobra missile ready for launch

Rear view of Cobra missile



Construction of Cobra missile (for description see text)

CHARACTERISTICS.

Type: Surface-to-surface anti-tank weapon system

Guidance Principle: Command to line of signt wire-guidance; optical gathering and tracking

Guidance Method: By control of spoilers in wings

Propulsion: Solid-propellant sustainer with separate non-jettisonable booster mounted below the missile

Warhead: (a) hollow charge 2.7 kg: penetration 500 mm armour

(b) ATS (anti-tank/shrapnel) 2.7 kg: penetration 350 mm armour prefabricated fragmentation with destructive effect within 10 m radius

Missile Length: 95 cm
Body Diameter: 10 cm
Wing Span: 48 cm
Launch Weight: 10.3 kg
Weight at burn-out: 8.0 kg
Maximum Speed: About 300 km/h
Range: 400-2,000 metres

DEVELOPMENT:

Cobra was designed and developed by Bölkow GmbH, the first design study being carried out in 1957. The system first went into service in 1960, since when more than 150,000 (including those manufactured under licence) have been supplied to the armed forces of 18 countries. A first generation missile, Cobra has been produced in two versions: the Cobra 2000 described here being slightly the heavier of the two and having a maximum range of 2,000 metres whereas the earlier Cobra had a maximum range of only 1,600 metres. It is still in production but its improved successor, Mamba (**2188.111**) has been so designed as to make it easy for countries using Cobra to change to the new system at whatever rate suits them best.

SIMULATOR:

The manufacturers make a special simulator for training purposes – the complete equipment for which is contained in a single field transport case. A standard control box is used by the operator and the target and missile presentation is by means of a dot and a circle on a cathode-ray tube.

MANUFACTURERS:

The complete system is manufactured by Messerschmitt-Bölkow-Blohm GmbH, Ottobrunn bei München, Germany. The warhead and sustainer motor are made by OerlikonBührle, Switzerland.

2188.111
MAMBA PORTABLE ANTI-TANK WEAPON SYSTEM

DESCRIPTION:

Mamba is an anti-tank missile first announced by MBB late in 1972. Of the same general type as Cobra (**2181.111**) it incorporates two major improvements in the missile, in addition to numerous other changes, and MBB have developed a completely new controller for the system. The new missile, however, will accept Cobra warheads and can be used with existing Cobra controllers by users wishing to change to the new weapon; and existing Cobra vehicle launchers can readily be modified to accept Mamba.

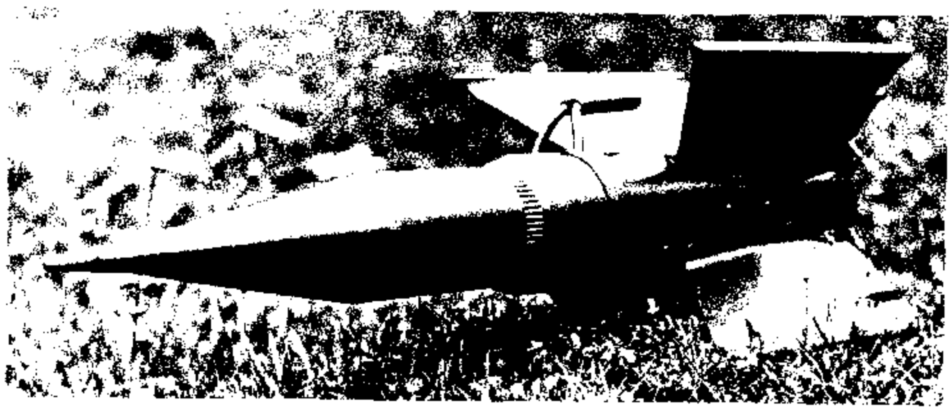
One of the major differences between Mamba and Cobra is that, whereas the latter used an oblique-thrust booster (to give a jump start) and an axial sustainer, Mamba has a one-cell dual-purpose oblique-thrust engine which not only retains the jump-start facility but also provides a weight compensation during the cruising phase. This saves the operator from having continually to counteract gravitational droop during the cruising phase. The other major change is the increase in maximum speed from 85 m/sec to 140 m/sec.

The new controller incorporates an extremely powerful monocular with an oblique (X7) eyepiece. This permits direct transition from observation with the naked eye to telescope magnification without head movement – thus avoiding the main difficulty of this transition. This control unit is completely independent of any power sources, batteries etc; it performs all the functions which are performed for Cobra by the test and control units; and it is operable from —40°C to +60°C.

Three output sockets from the controller can be connected to single missiles and a fourth can be connected either to a fourth missile or an eight-outlet junction box – giving a total control capability of 11 missiles selected by a switch on the controller. Missile launching is by push-button and guidance by joystick, power for the ignition impulse and the joystick signals being provided by a clockwork motor operating a generator. One winding of the motor suffices for eight launches.

The Mamba system thus comprises only the missile and the control unit. It is conveniently packaged in a water-, dust- and tropic-proof pack which is of a convenient size for carrying and stacking. Like Cobra Mamba can be fitted with alternative shaped-charge, ATS or training warheads and these are easily interchangeable.

Mamba is primarily designed to be launched from the ground; and since it can be laterally diverted up to 45° from its launching direction its envelope of action is very wide. If required, however, it can also be launched from a vehicle and a standard 3-missile launching frame has been designed for this purpose. Any kind of vehicle can be fitted with this frame, on which the missiles are mounted in a ready-to-fire position but from which they are easily removed. The controller can be either mounted on the vehicle or removed for remote operation.



Mamba anti-tank missile

CHARACTERISTICS:

Type: Surface-to-surface anti-tank weapon system

Guidance Principle: Command to line of sight with optical tracking

Guidance Method: Wire-guidance control of wing-mounted spoilers

Propulsion: Single-cell, dual-purpose- solid-propellant, oblique-thrust rocket motor

Warhead (a) Hollow charge, 2.7 kg, 475 mm armour penetration
(b) Anti-tank shrapnel (ATS), 2.7 kg, 250 mm penetration plus shrapnel over 10 m radius area
(c) Dummy for training. All warheads interchangeable

Missile Length: 955 mm

Body Diameter: 120 mm

Wing Span: 400 mm

Launch Weight: 11.2 kg

Maximum Speed: 140 m/sec

Effective Range: 300-2,000 m

Flight Times: 500 m 6 sec
1,000 m 10 sec
2,000 m 17.5 sec

Controller Dimensions: 300 × 250 × 100 mm, 9.55 kg

Packed Missile (with accessory bag): 365 × 402 × 605 mm, 18 kg

Cable System (including junction box, reel etc): 393 × 408 × 416 mm, 26 kg

TRAINING:

A special training aid, Type 112/1 SV, has been designed. This is a simulator using a combat area presentation on a TV screen with superimposed symbols – which move appropriately – to represent target and missile. The trainee operates a standard controller in conjunction with this display.

STATUS:

Development. The system was demonstrated to German Government officials in June, 1972.

INDIA

2286.111
INDIAN ANTI-TANK MISSILES

So far as is known, India has not yet undertaken the design and development of any anti-tank missiles. The budgeted defence expenditure under the new Five-Year Plan which started in April 1974, however, included a substantial sum for the provision of guided missiles, including anti-tank missiles.

In 1970/71 the firm of Bharat Dynamics Ltd was set up to undertake work on guided missiles for the Indian forces and specifically to implement a licence agreement made with Aérospatiale (France) in 1970 and covering a programme of co-operation aimed at Indian production of the SS-11 (**2139.111**) anti-tank missile.

Over a period extending from March 1971 to September 1973 the French manufacturers supplied information, parts and engineering assistance to the Indian company. The first batch of missiles made from sub-assemblies supplied by Aérospatiale was delivered from the Indian production line twelve months after the licence agreement was concluded and at the end of 1973 it was announced that the Indian company was in a position to make the complete missile without French assistance.

MANUFACTURER:

Bharat Dynamics Ltd, Hyderabad, India.

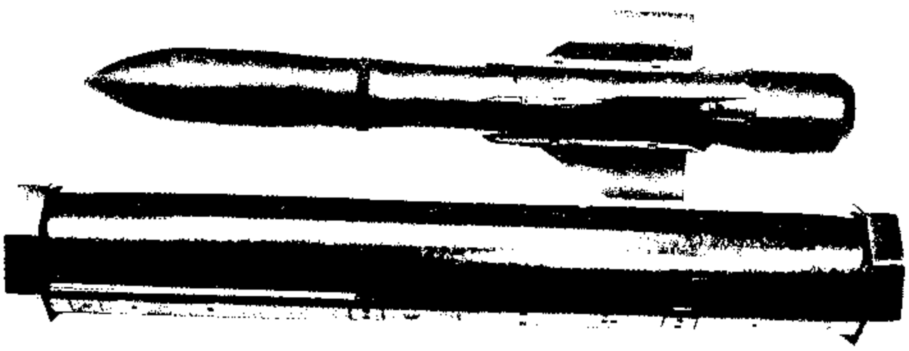
INTERNATIONAL

2212.111
HOT ANTI-TANK MISSILE

DESCRIPTION:

HOT (Haut subsonique Optiquement téléguidé tiré d'un Tube) is a heavy anti-tank weapon being developed by Aérospatiale and Messerschmitt-Bölkow-Blohm. With low-speed spin-stabilisation like Milan (**2215.111**), it is a tube-launched, wire-guided missile of larger size and with a higher performance than Milan – development of which is running to parallel with it – but has the same general principles of operation. HOT is planned as a replacement for the SS 11 (**2139.111**) missile; and its mission profile corresponds to a NATO requirement for a missile to operate primarily from armoured or un-armoured vehicles and helicopters.

Like Milan, the missile has tail fins which fold



HOT missile and its launcher/transporter tube

down against the body when it is in its launch tube are open out to spin stabilise it in flight. Because of its comparatively high speed the time of flight to a target is only about one half of that for the Aérospatiale SS 11. Guidance is by means of the TCA type of optical/infra-red system developed for the Aérospatiale Harpon missile (**2095.111**) with optional manual guidance.

With the TCA system of guidance, all the operator has to do is to aim carefully at the target with an optical sighting device. When the missile is launched, infra-red radiation from its tracer flares is detected by a precision goniometer that is associated with the optical sight and that has its reference axis accurately parallel to the optical axis. Departure of the missile from the optical axis gives rise to an angular error signal which can be combined with an estimate of range (based on the known flight characteristics of the missile) to give a measure of the linear departure of the missile from the line of sight. This measurement is then used to generate command correction signals for the missile whose flight is controlled by means of a jet vane system.

OPERATION:

To operate the system, therefore, once the target has been visually acquired, all that the operator has to do is aim carefully at the target, launch the missile and maintain his aim steadily during the missile's flight. An advantage of this guidance system is that, because the departure of the missile from the line of sight is measured by the system, the amount of flight correction required can be determined to a similar degree of accuracy and, as a result, the initial gathering of the missile on to the line of sight can be accomplished quickly. This has the important effect of giving the system a good short-range performance.

HOT can be fired from armoured or other vehicles, from helicopters, from ships or from dug-out positions and in all conditions of visibility that permit the operator to aim at the target. In particular, a special installation has been designed for the widely-used M-113 APC and enables a twin launcher and periscope to be added to the vehicle with minimum modification. Weight of the complete HOT unit for such an installation is 500 kg.

The missile's hollow charge warhead is effective against all known types of tank and against ships and field fortifications. The tube from which the missile is fired serves also as a transport and storage container. After the missile is fired this tube is thrown off automatically and according to the nature of the installation, a new tube can be loaded manually or automatically. Some typical launcher arrangements are described below.

LAUNCHING GEAR 800 (MANUAL):

This gear is particularly suitable for light vehicles. The missile is locked manually on the ramp and aimed roughly before firing by swivelling the entire gear. Precise aiming is achieved by means of a periscope.

LAUNCHING GEAR 800 (HYDRAULIC)

In this gear the missile is locked hydraulically on the ramp. The target is tracked by the periscope aiming system and the entire launching gear is moved in elevation and azimuth by the hydraulic synchronising system.

LAUNCHING GEAR FOR TURRET VEHICLE

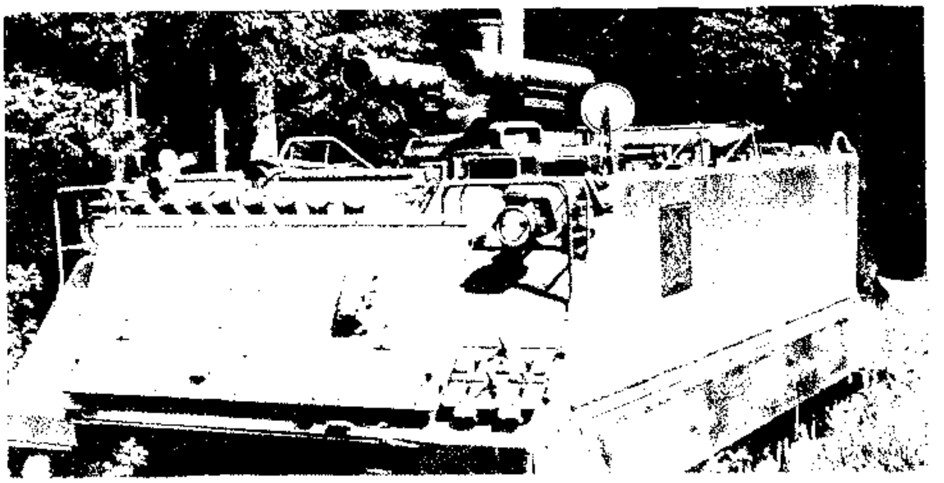
Here the missiles are carried in launching boxes on either side of the turret (see photograph). The guidance system is divided into small units for flexibility in installation and can be associated with any available type of gunner's sight. Aiming is accomplished by turning the turret.

LAUNCHING GEAR FOR CASEMATE VEHICLE

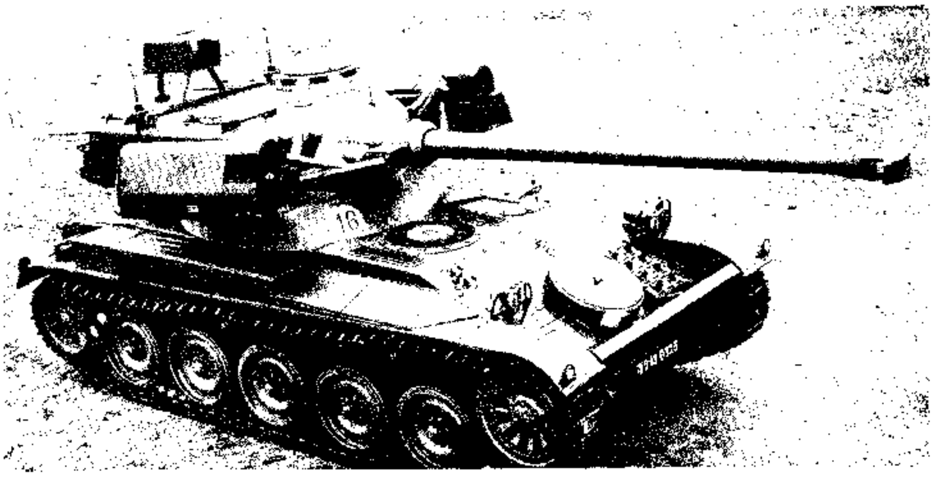
This consists of either one or two retractable clamp systems and a periscope guidance unit. Empty launch tubes are automatically thrown clear after launching and reloading is automatic on retraction of the clamp system into the vehicle. The clamp system is controllable in elevation and azimuth, and slaved to the motion of the periscope guidance unit.

CHARACTERISTICS:

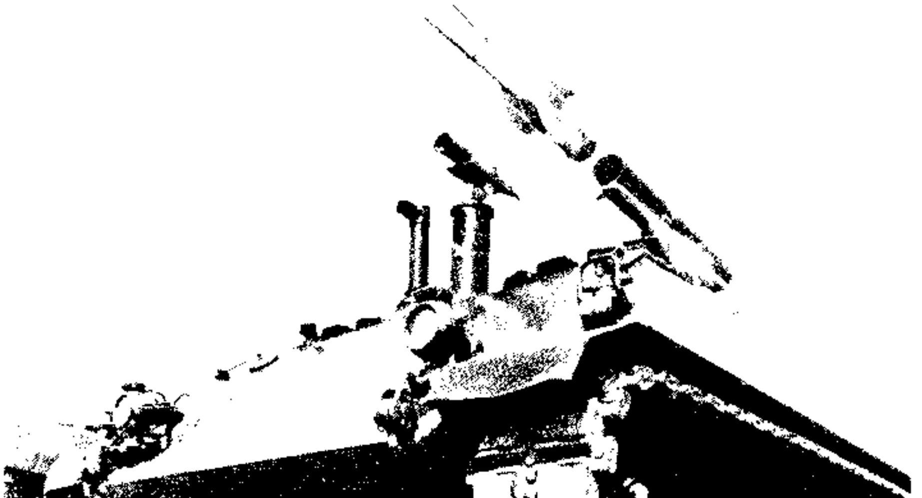
Type: Long-range, vehicle-mounted, wire-guided, anti-tank weapon with shipborne and airborne applications



HOT Launching Gear 800 (Manual) mounted on a M-113 APC. The aiming periscope can be seen between the two missile tubes



AFV installation of HOT anti-tank weapon system



Launch of a HOT missile from the Casemate Vehicle Launcher

Guidance Principle: Command to line-of-sight. Optical aiming with automatic infra-red tracking. Optional manual tracking

Guidance Method: Wire guidance control of jet vane system

Propulsion: Solid-propellant booster and sustainer

Warhead: Hollow charge

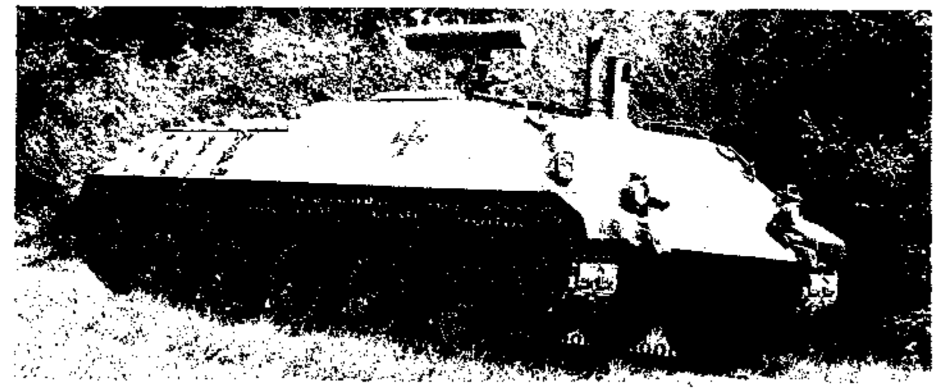
Missile Length: 1.275 metres

Missile Diameter: Warhead, 136 mm. Span 310 mm

Launch Tube Length: 1.3 metres

Launch Tube Diameter: 175 mm
Weight: Missile and container 28 kg. Missile at launch 22 kg
Maximum Speed: 950 km/h
Flight Duration: 2,000 8.7 s
3,000 m 12 5 s
4,000 m 16.3 s
Range: 75 m to more than 4 km
Penetration: More than 800 mm of solid armour. NATO triple-armour target at 65° incidence
Operating Conditions: —40° to +52°C at up to 95% r.h.

DEVELOPMENT:
The first design study for the system was made in 1964. Development is now complete and the weapon system has been evaluated (including helicopter trials) by the French and West German Forces. It is also one of the three systems (with TOW and Airstrike Swingfire) being considered for helicopter-launched applications by the British Army.

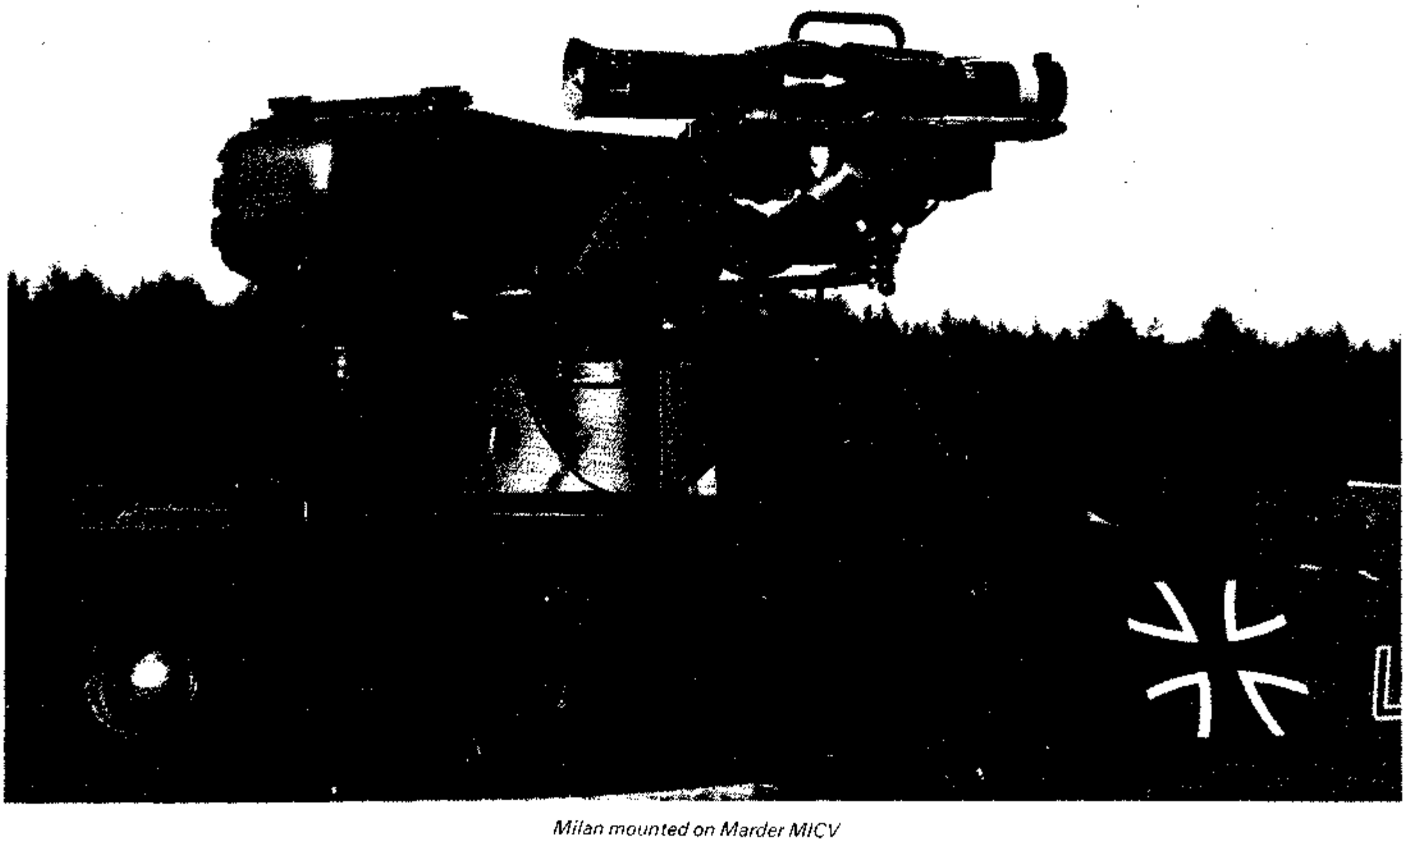


German Tank Destroyer with HOT Casemate Vehicle Launcher

MANUFACTURER:
Responsibility for management, sales and production is now vested in Euromissile, 37 Boulevard de Montmorency, 75016-Paris, France.

2215.111
MILAN ANTI-TANK MISSILE
DESCRIPTION:
Milan (Missile d'Infantrie Léger ANtichar) is a wire-guided, spin-stabilised, anti-tank missile system.
An advanced second-generation system, Milan incorporates a semi-automatic guidance technique that requires the gunner to do no more than maintain the cross wires of his guidance unit on the target during the missile's flight. The system comprises a missile in a container and a launch and control unit. Before the launch the container – which also serves as a launch tube – is mounted on the launch and control unit. This in turn can be either mounted on a tripod to be fired from a ground position or, mounted on a pivot, from a vehicle.
Although heavier than some of the small first-generation anti-tank missiles, Milan is readily portable. It is also suitable for operation from armoured or unarmoured vehicles. In its simplest form operation is effective in daylight, at dawn and dusk and, by means of battlefield flares, at night. It can be fired over fresh or salt water.

Milan – prone firing position



Milan mounted on Marder MICV

OPERATION:

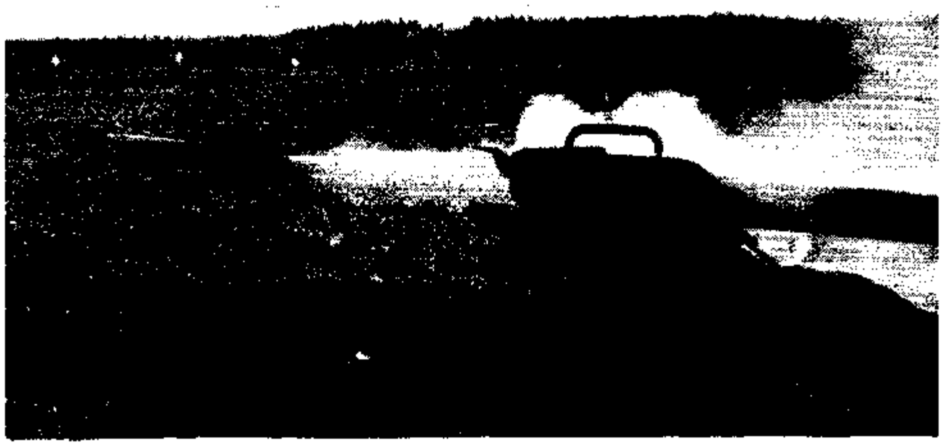
At launch the missile is popped from its container by a plunger which in turn is propelled by a gas generator located at the rear of the launch tube and working on the recoilless principle. This end of the tube is protected for storage and transit by a cap which must be removed before firing.

As the missile emerges from the tube, the tube is disconnected from the launch unit, and the forces in the system are sufficient to throw it backwards from the launcher to a distance of about three metres, leaving the launcher ready for reloading.

When the missile is ejected from the tube its wings, which impart a slow spin to the missile, flick open. The missile then coasts forward until, at a sufficient distance from the launcher to avoid harm to the gunner, the sustainer rocket ignites.

Built into the launcher/control unit is an infra-redTCA guidance system similar in operation to that described above for HOT (**2212.111**). After launching, the missile is gathered to the gunner's line of sight using wide-angle detection. Detection sensitivity in this phase is presumably relatively low but at close range the signal strength from the infra-red flares in the missile's tail will be high. For subsequent guidance narrow-angle detection is used.

Milan – standing firing position



Launching a Milan anti-tank missile. Picture shows missile in flight and container tube being ejected to the rear. Note that the periscope type sight enables the firer to keep his head well down

CHARACTERISTICS:

Type: Surface-to-surface, man-portable, anti-tank weapon system

Guidance Principle: Automatic command wire-guidance

Guidance Method: Optical tracking of target only. Automatic infra-red tracking of missile and control by varying thrust of sustainer efflux

Propulsion: Booster-ejector in tube. Single solid-propellant sustainer

Warhead: Hollow charge

Penetration: Against triple NATO target at 65° incidence average of 352 mm steel perforated. NATO heavy tank target perforated on nearly 90% of occasions: medium tank target on nearly 99% of occasions

Missile Length: 0.77 metre

Body Diameter: 0.09 metre

Fin Span: 0.27 metre

Weights: Missile and container: 11.5 kg; Launcher and Control Unit with tripod: 15.5 kg

Max Speed: 200 m/sec

Range: 25-2,000 metres

Time of flight: 7.1 sec to 1,000 m. 12.5 sec to 2,000 m

DEVELOPMENT:

Following the Franco-German agreement discussion started between Nord-Aviation and Messerschmitt-Bölkow in 1962 a design study was completed in 1963. Technical evaluation and firing demonstrations by and for the French and West German forces were completed in 1971. User trials in France, Germany and other countries followed; as a result of which the French Army has ordered the weapon and Germany is expected to follow suit. In June 1972, a successful series of demonstrations was given to representatives of some 30 countries. During the official Franco-German trials, which were designed to test the weapon's efficiency in a wide range of environmental conditions, a hit probability of 88.6% was established in 665 firings.

STATUS:

First batches of 10,000 missiles and 200 launch units have been ordered for both French and West German armies. Further orders are expected soon.

Large-scale production has been planned on the assumption of a total market of 200,000 missiles and 5,000 launch units. Initial production is planned at 1,000 missiles per month rising to 2,000 with launch units running at 50 per month.

Milan on Kraka vehicle

MANUFACTURERS:

Messerschmitt-Bölkow-Blohm GmbH, Munich, and Aérospatiale, Paris, are main contractors. Eltro, Luchaire-STRIM and SAT are also involved.

Management, sales and responsibility for production: Euromissile, 37 Boulevard de Montmorency, 75016-Paris, France.

2238.111
MOSQUITO ANTI-TANK MISSILE

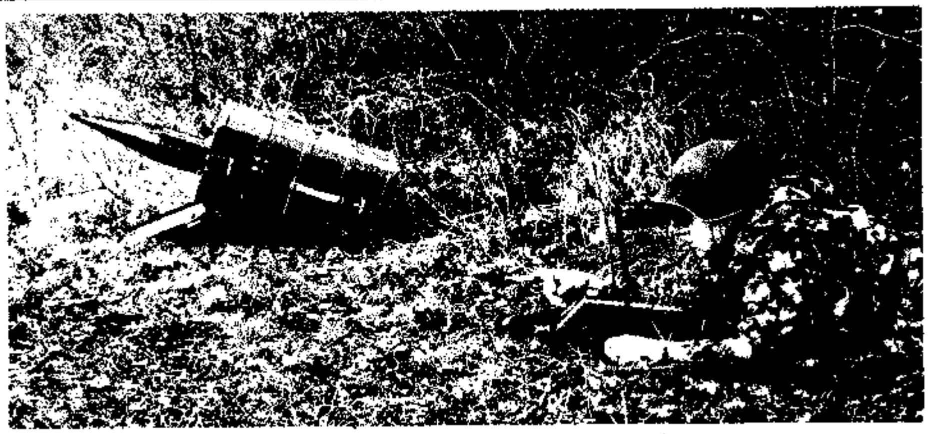
DESCRIPTION:

Mosquito is a wire-guided roll-stabilised infantry anti-tank guided weapon system. It can be carried and operated by one man using an optical sight and joystick control to guide the missile to the target.

MISSILE:

The Mosquito missile is of conventional design and consists of a cylindrical glass-fibre body and folding cruciform wings of sandwich construction. In flight the missile is controlled by vibrating spoilers on the trailing edge of each wing and is roll-stabilised by a gyro.

For storage and transport, a single Mosquito is



Mosquito anti-tank missile

packed into a container, with its wings in place and only the warhead detached. Alternative warheads are a hollow charge type capable of penetrating more than 66 mm of armour plate, or a fragmentation type. The complete package, with missile inside, weighs 22.0 kg. Six Mosquitos can be transported, ready for firing, on a Puch-Haflinger light cross-country vehicle. This weapon has also been mounted on Agusta-Bell 47 helicopters.

For training purposes, the Mosquito can be fitted with a parachute recovery system instead of a warhead.

CHARACTERISTICS:
Type: Man-portable, anti tank guided missile
Guidance Principle: Command to line of sight with optical aiming
Guidance Method: Manual command from optical tracking. Wire-guided control of vibrating spoilers on missile wings
Propulsion: Two stage solid-propellant rocket motor
Warhead: Choice of hollow charge or fragmentation. 4 kg
Missile Length: 1.11 metres
Missile Diameter: Body 12 cm. Span 60 cm
Launch Weight: 14.1 kg
Cruising Speed: 90 metres/sec
Range: 360-2,300 metres

STATUS:
The weapon system is in production.

MANUFACTURER:
Contraves Italiana SpA, Via Tiburtina 995, Rome.

2251.111
SPARVIERO ANTI-TANK MISSILE

DESCRIPTION:
Sparviero (Hawk) is the name given to a third generation anti-tank missile currently under development and intended to enter service in the 1980s.

An IR guidance system developed by Officine Galileo will be used for the system, which otherwise will comprise an optical aiming device, a tripod mounted launcher and a missile stabilised by flip out fins and carrying a 4 kg hollow-charge warhead more than 3,000 metres. All up weight will be 60 kg of which the missile accounts for 16.5 kg.

MANUFACTURERS:
System: Breda Meccanica Bresciana SpA, Via Lunga 2, 25100 Brescia, Italy.
IR Guidance: Officine Galileo, Florence, Italy.

JAPAN

2262.111
KAM-3D ANTI-TANK MISSILE

DESCRIPTION
KAM-3 is a command-controlled wire-guided anti-tank missile system which is standard equipment for the Japan Ground Self-Defence Force.

The KAM-3D missile has an orthodox configuration, with a cylindrical metal body and cruciform metal wings incorporating full-span trailing-edge spoilers for control. Propulsion is by a two-stage Daicel Co solid propellant rocket-motor, the booster stage of which accelerates the missile to its cruising speed in 0.8 seconds, after which the sustainer stage maintains this speed.

The missile can be fired singly or in multiple units by infantry and is carried by jeeps and helicopters. It is launched at an elevation of 15° and the operator controls it via an optical tracking system, using a flare by day and the sustainer rocket exhaust by night as a visual reference. A gyro-stabilisation system is embodied in the missile. A two-man firing team is required to operate the system. Control is achieved by using a thumb-button control box.

CHARACTERISTICS:
Type: Man-portable wire-guided anti-tank missile
Guidance Principle: Command to line-of-sight with optical tracking
Guidance Method: Wire-guidance control of vibrating spoilers on wing trailing edges
Propulsion: Two-stage solid-propellant rocket motor
Missile Length: 100 cm
Missile Diameter: Body 12 cm. Span 60 cm
Launch Weight: 15.7 kg
Cruising Speed: 85 metres/sec
Turning Radius: 250 metres
Range: 350-1,800 metres

DEVELOPMENT:
Following a design study carried out in 1956, development of this missile was started in 1957, under a contract awarded by the Technical Research and Development Institute of the Japan Defence Agency. The KAM-3 weapon system was adopted as standard equipment of the JGSDF in 1964 after several hundred test rounds had been fired, and has the official designation, Type 64 ATM. Trials showed that the missile's velocity control system enabled three out of four unskilled operators to hit a target with their first round after completion of a two week training course with the ATM simulator. Skilled operators could score 19 hits in 20 firings.

TEST AND TRAINING EQUIPMENT:
A field test set (KAM-3TE) and a simulator (KAM-3TP) are made by the main contractor

MANUFACTURERS:
Manufacturers of the complete system are Kawasaki Heavy Industries Ltd, Aircraft Division, 4-1 Hamamatsu-cho 2-chome Minato-ku, Tokyo. Other manufacturers known to have been associated with the system are:
Warhead – Daikin Kogyo Co
Rocket Motor – Daicel Co.; Nippon Oil & Fats Co.
Missile Guidance – Nippon Electric Co.
Guidance Wire – Fujikura Cable Works.

2263.111
KAM-9 (TAN SSM) BATTLEFIELD MISSILE

DESCRIPTION:
KAM-9 is an extended range, higher-performance version of the KAM-3, which can be used against armoured vehicles or both land and water. The missile is launched from a tubular container, which is used also for transport and storage. A solid-propellant launch motor ejects the missile from the container to a safe distance from the operator; the flight motor then ignites and accelerates the missile to its cruising speed in a few seconds.

Prior to launch, the container is placed on the launch and tracking unit, which consists of the firing mechanism, sight, and missile checkout device. The optical sighting device is designed to be operated by one man. During the missile's flight, the operator simply keeps the optical sight trained on the target, and sensors translate the course deviation to electrical signals which are fed into computer. The computer then feeds course corrections into the missile through the guidance cable

DEVELOPMENT:
Development of the missile was instituted by the Technical Research & Development Institute, Japan Defence Agency, and the first design study was started in April 1964. The system is now at the engineer production stage.

CHARACTERISTICS:
Type: Surface-to-surface, wire-guided tactical missile
Guidance Principle: Command to line-of sight with optical aiming and automatic – probably infra red – tracking
Guidance Method: Wire guidance. No other details known
Propulsion: Solid-propellant booster and sustainer
Warhead: Armour piercing. Type unknown
Missile Length: 1.5 metres
Missile Diameter: Body 15 cm. Span 33 cm

MANUFACTURERS:
System – Kawasaki Heavy Industries Ltd.
Flight Motor – Daicel Co. Ltd.
Launch Motor – Nippon Oils & Fats Co.
Guidance System – Nippon Electric Co.
Guidance Wire: Fujikura Cable Works.

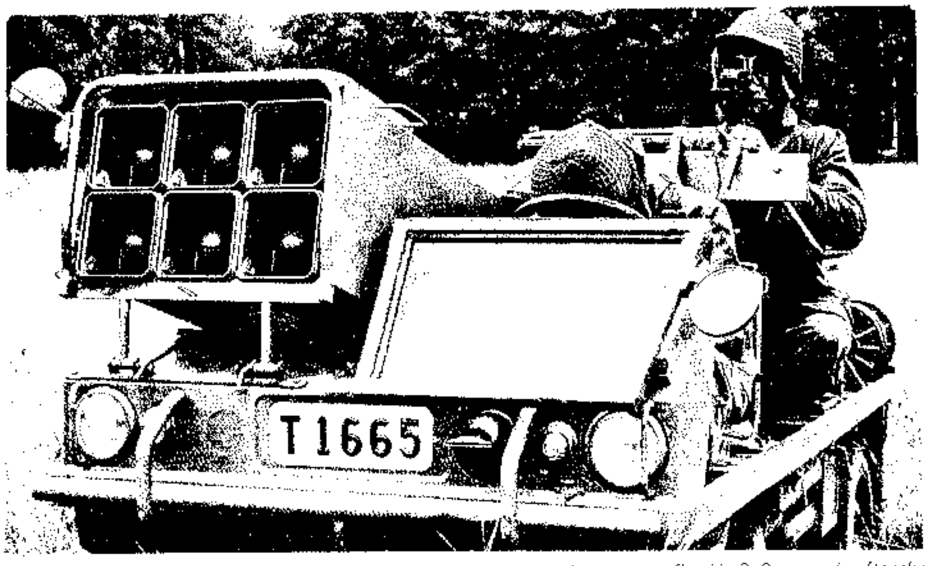
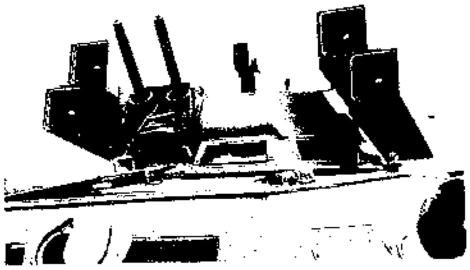
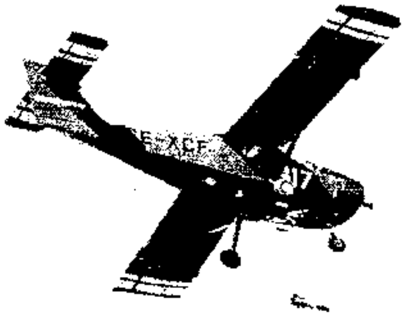
Launching a Bantam missile



The 6 Bantam missiles pointing forwards on the Puch-Haflinger jeep can be fired in 2-3 seconds after the vehicle has stopped. Six more missiles are carried at the rear of the jeep



Four Bantam missiles installed on the turret of a Cadillac Gage V-100 AFV



Bantam launched from SAAB MFI-17

2363.111
BANTAM ANTI-TANK MISSILE

DESCRIPTION:

Bantam is a small wire guided anti-tank missile, designed for operation by a single infantry soldier, but suitable also for use when mounted in land vehicles or small military aircraft. The missile has a hollow-charge warhead and is said to be able to "kill" the most modern heavy tank.

The complete system in its simplest configuration comprises the missile in its combined transport and launching container with carrying harness, a control unit and 20 metres of cable. All this weighs only 20 kg of which the launching weight of the missile is 7.5 kg.

OPERATION:

Time for setting up and firing is about 25 seconds. The container is positioned on the ground with the missile pointing in the direction of interest and the operator stations himself in a convenient position up to 20 metres away (or, with extra cable, up to 120 metres away) with the control unit which is connected to the container by cable. The control unit is fitted with a sighting device and a joystick to control the flight of the missile, command signals being conveyed through the wire trailed from the missile in flight.

Each wire spool contains 2,000 metres of guiding wire and in each is mounted a microswitch. One of these ignites the sustainer and up to four (as preselected by the operator) tracer flares in the rear of the missile after 40 metres of flight, the other arms the warhead after 230 metres.

When the missile is launched from the container its folding wings open. These have bent rear corners to give the missile rotation in flight and vibrating spoilers on their trailing-edges which are used to control the direction of flight. The missile battery which powers the control and fusing mechanisms is only activated when the missile starts its flight.

Also activated on firing is the missile gyro. This is energised by a powder pellet and after the missile has travelled 3 cm from rest a pin is withdrawn that uncages the gyro. Guidance signals for the spoilers are amplified by a transistor amplifier in the missile and passed to the spoilers by way of a commutator connected to the gyro. Due to the rotation of the missile the spoilers on each pair of wings switch from traverse guidance to elevation guidance or vice versa at each quarter rotation.

CHARACTERISTICS:

Type: Surface-to-surface anti-tank guided missile with air-to-surface capability
Guidance Principle: Wire guidance
Guidance Method: By control of vibrating spoilers on trailing edges of wings
Propulsion: Two-stage (booster/sustainer) solid-propellant motor
Warhead: Hollow charge; electrical fuse: weight 1.9 kg; armour penetration better than 500 mm
Missile Length: 0.85 metres
Missile Diameter: Body: 0.11 metre. Span: 0.40 metre
Weights: Container with missile: 11.5 kg; Minimum system with one missile: 20 kg
Range: Less than 300 metres to 2,000 metres
Hit Probability: 95-98% at 800-2,000 m
Cruising Speed: 85 metres/sec

DEVELOPMENT HISTORY

Bantam was designed and developed by AB Bofors as a private venture started in 1956. It is in large-scale production for the Swedish and Swiss Armies with which it is standard equipment having gone into service in Sweden in 1963 and Switzerland in 1967.

In addition to its use as an infantry weapon, Bantam can be used from land or other vehicles. In particular it has been designed into the Puch-Haflinger light cross-country vehicle, being available in this installation both for direct fire from the vehicle or for off loading for use by individual infantrymen.

Bantam also has air to surface applications. Missiles have been fired successfully from both helicopters and light aircraft.

MANUFACTURERS

Manufacturers of the complete system, of associated test instruments for the missile and of a firing simulator for training are:

AB Bofors, S-690 20 Bofors, Sweden.

2450.111
SWINGFIRE ANTI TANK MISSILE

DESCRIPTION:

Swingfire is a long range command-controlled anti-tank weapon system designed primarily for firing from a vehicle and capable of engaging and destroying the heaviest armour. The missile is wire-guided, command signals being generated by an operator's joystick control, and the commands are interpreted by the missile as demands for a change of heading, thrust vector control is employed.

An important feature of the system is its ability to operate with the firing vehicle concealed behind cover in such a way that there is no clear optical sight-line from launcher to target. The operator can be stationed a considerable distance (over 50 metres) from the launcher, and the missile will be automatically gathered into his field of view by means of the automatic programming of the initial flight of the missile.

Two basic methods of operation are possible. In one, in which the missile is controlled from the launching vehicle, the operator uses a periscopic sight that forms part of the main vehicle installation and can engage targets in his field of view over a 90 degree arc – that is, 45 degrees on either side of the direction in which the missile launcher is pointing. In the other method the operator uses a portable separation sight and stations himself in a suitable observation position while the launch vehicle remains concealed in a hollow or behind a building in any direction relative to the operator. A variation on this latter method is the use of a pallet-mounted system: since the weapon is battery operated it can be transported to a selected operational site and left there to be fired by an operator with a separation sight.

A typical vehicle installation comprises the periscope sight and joystick unit, a junction box and sequence firing unit, a programme generator and data store, a vehicle tilt compensating unit, a missile selector, a number of missiles, a power supply and a fault location indicator. A plug-in point permits the separation sight cable to be connected to the system. The system can be installed in almost any kind of military vehicle and installations have been devised for a wide range of tanks, armoured personnel carriers, armoured cars and scout cars. In some instances provision can be made for reloading within the vehicle in which case a rate of fire can be obtained that is comparable with that of a gun system. Vehicle installations do not require traversing or elevating gear, and the missiles can be fired from launcher boxes stowed in specially prepared bins or attached externally to the vehicle at the correct launch attitude. When the separated mode of fire is being used, vehicle tilt compensation is provided by the tilt unit. In all cases emphasis has been laid on protecting the equipment and the crew so that the system has a high degree of survivability on the battlefield.

Operation:

After the launch the missile is gathered into the operator's field of vision by the automatic gathering phase in the programme generator which functions in both azimuth and elevation. The inputs to this generator are the relative positions of the launcher, the operator, and the target; the operator-launcher relationship being predetermined when the periscope sight is used and separately programmed in when the separation sight is used.

When firing takes place from the vehicle the operator sets a selector switch to "Direct Fire" and aligns his vehicle sight with the target, thereby automatically feeding the required azimuth and elevation angles into the programme generator. When the separation sight is used, the separation cable is run out to the sight, positioned and levelled with its reference mark parallel to the launch direction. In the vehicle the selector switch is set to "Separate Fire"; and the programme generator is adjusted to allow for the vehicle tilt angles, the estimated distance of the separation sight, the angle between the launcher direction and the separation sight and the angle of elevation of the highest point over which the missile must fly. These last measurements are made with an alignment gauge that forms part of the installation. Target angles are then obtained from the separated sight as in the direct fire role.

In this way the missile is guided approximately onto the target sight line and final gathering is carried out by the operator. Swingfire has a velocity control system and movement of the operator's joystick in any direction alters the heading of the missile in that direction: maintaining the joystick stationary once the missile is framed in the target is sufficient to hold it on its collision course. Pitch and yaw demands are conveyed to the missile by the trailing wires and are referred to roll and heading gyros in the missile autopilot. Different signals are used to control the missile heading by altering the direction of thrust of the main motor and the servo loop is completed by a heading response unit so that the thrust deflection is reduced as the missile approaches the demanded heading.

Characteristics:

Type: Mobile anti-tank guided missile system. Pan-climatic. Missiles prepacked in hermetically sealed launcher boxes

Guidance Principle: Wire-guided. Heading demand signals referenced to autopilot. Optical sighting with automatic initial gathering. Manual control (local or remote). X1 or X10 magnification sights

Guidance Method: Thrust deflection of main motor

Propulsion: Rocket motor (solid propellant) designed to give low initial acceleration thus facilitating the engagement of targets at short ranges

Warhead: Hollow charge powerful enough to defeat all known combinations of armour

Range: Minimum – from less than 150 m at direct fire to 300 m with maximum separation. Maximum – 4,000 m

Fire Arcs: Azimuth +45 deg. without turret traverse. Elevation +20 deg to —15 deg relative to mounting plane

Special Features: Ease of concealment. Immunity to ECM

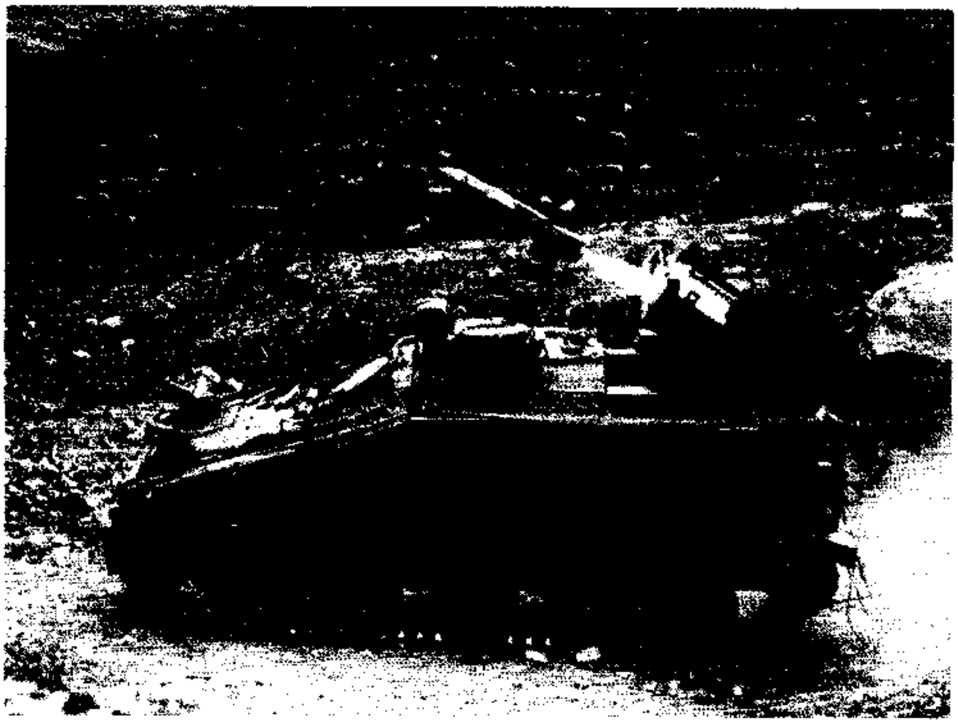
Development History:

British Aircraft Corporation (Guided Weapons) Ltd. based their design, development and production programmes on experimental work originally done by Fairey Engineering Ltd. The first design study was made in 1958 and the first public announcement concerning the system was made in 1962. The system went into service with the British Army in 1969. Although already extremely versatile and effective the system is regarded as being suitable for further development.

Future Development:

Work is now well advanced on three new applications of the Swingfire System. These are:

1. **Striker** – The Guided Weapons vehicle in the new CVR(T) Series.
2. **Infantry Swingfire** – A crew-portable version. It can be transported on and fired from any vehicle or trailer from a 1-ton truck or ¾-ton long-wheelbase Land Rover upwards. It can be carried over short distances (of the order of 400 metres) and deployed by its 3-man crew. For this purpose it is broken down into 2 manloads. When in action it is always used in the "separated fire" mode and covers an arc of fire in excess of 180° without traversing the launcher. It can be air-transported and air-dropped as a complete system. The British Army designation is **Beeswing**.
3. **Helicopter Installation** – Work is in hand to



Swingfire launch from Striker combat reconnaissance vehicle during firing trials. 1974 photograph

Infantry Swingfire – a version of the Swingfire system being developed for the British Army develop Swingfire as a "button-on system" for the new range of British Army Helicopters. As it is an easily removable system it will be readily adaptable to other helicopters of similar load carrying capacity to the British Army Gazelle and Lynx helicopters. The manufacturer's designation is **Airstrike Swingfire** and the British Army's, **Hawkswing**.

TEST AND TRAINING EQUIPMENT:

In addition to the built-in fault-locating equipment referred to above, the manufacturer offers a complete range of test equipment for unit and field workshop repair. A field trainer, for use in the vehicle or with the separated-fire sight, is available for continuation training in the field, whilst a multi purpose trainer, which provides a synthetic target and a means of assessing a trainee's performance, is available for initial training either in the classroom or in the field.

MANUFACTURER:

British Aircraft Corporation (Guided Weapons) Ltd, Stevenage, Hertfordshire, England.

2471.111

VIGILANT ANTI-TANK MISSILE

DESCRIPTION:

Vigilant is a man-portable wire-guided anti-tank missile system. Suitable for use by infantry, armoured regiments or paratroops it can be brought into action in seconds and is lethal against the heaviest battle tank.

In its simplest configuration the system comprises a launcher box containing one missile, a sight controller, a pocket battery and a length of interconnecting cable. The launcher box is set down on the ground with the missile inserted, pointing in the direction from which a threat is anticipated, and the operator, who carries the sight controller and its associated battery, takes up a suitably unobtrusive position where he has a good field of view. This position may be up to 63 metres from the launcher box. Thus positioned the operator can engage targets over arcs of fire of +10° in elevation and +35° in azimuth and at ranges of from 200 to 1600 metres.

To engage a target, the operator grips the sight controller with both hands, with a finger of one hand on the firing trigger and the thumb of the other on the guidance control cup, and fires. The thumb controller transmits signals to the missile guidance system through a wire link trailed out by the missile when in flight and operates as a velocity controller – so that movement of the cup in any direction alters the missile's heading in that direction: restoration of the cup to its initial position re-establishes the initial heading with the missile travelling on a path displaced from, but parallel to, its original path. Once the missile flare is framed in the target, therefore, centring the cup is sufficient to hold the missile on its collision course.

For daylight operations the missile is fitted with a special rear flare that can readily be seen by the operator. At night the light from the thrust pipe is found to be sufficient. The Sight Controller is fitted with a monocular sight that is useful for long-range engagements.

Vigilant missile at the moment of launch from the twin traversable launcher

Vigilant missile leaving its launcher

In the missile is a gyro autopilot, signals from which are combined with the elevation and azimuth demands from the thumb control and fed to a roll-resolving commutator. This ensures that whatever may be the roll-attitude of the missile the correct pair of control surfaces is actuated so that missile movement is in the same direction as thumb movement.

As the missile changes direction the gyros measure the change and bias the positioning signals back as the demanded heading is approached. The missile thus continues to fly on this heading until the removal of the demands from the thumb cup initiates the reverse process that brings the missile back to a new path parallel to its original path. The missile responds only to thumb control signals: disturbances caused by high winds are automatically corrected by the autopilot.

Optional system extras include a selector box to enable one operator to control up to six missiles in turn; a remotely traversable launcher containing two missiles that can be slewed through 340° in 8 seconds; a selector box that enables one operator to control three such launchers. Other system variants include mountings for scout cars or Land Rovers.

CHARACTERISTICS:

Type: One-man portable anti-tank missile system. Pan-climatic

Guidance Principle: Wire-guided. Heading demand signals referenced to missile autopilot. Optical sighting. Manual or semi-automatic control

Guidance Method: Servo-controlled surfaces in pairs

Propulsion: Two-stage solid-propellant motor

Warhead: Hollow charge. Weight in excess of 5 kg with fuse

Range: 200-1,375 m

Special Features: East of concealment. Immunity to ECM

DEVELOPMENT HISTORY:

Vigilant was developed by Vickers-Armstrongs (Aircraft) Ltd, as a private-venture weapon system from a design specification issued in 1956. Test firings took place in 1957-58 and the production weapon was tested in 1960. The system has since been widely sold and went into service with the British Army and the Defence Forces of Finland and Kuwait in 1963, of Saudi Arabia in 1964 and of Libya in 1968 and, on Ferret 2/6, to the Abu Dhabi Defence Forces in 1971.

TEST AND TRAINING EQUIPMENT:

The manufacturers, British Aircraft Corporation, offer a comprehensive range of test equipment for use with the system together with a classroom trainer and a field trainer.

THE UNITED STATES OF AMERICA

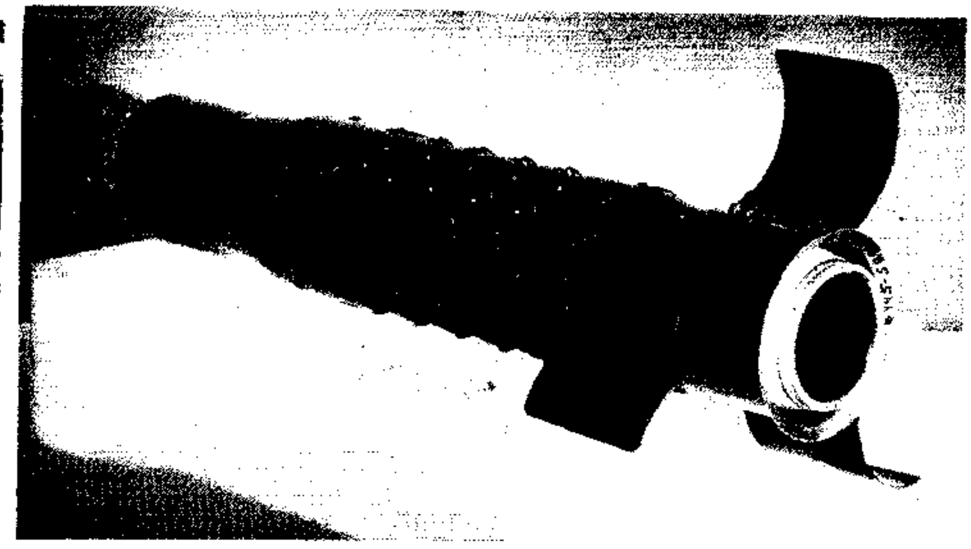
2573.111

DRAGON ANTI-TANK/ASSAULT WEAPON

DESCRIPTION:

Formerly known as MAW (Medium Anti-tank Assault Weapon System) Dragon has been developed for the US Army and Marine Corps as a weapon light enough to be carried and shoulder-fired by one man; yet having a warhead large enough to destroy most armour and other infantry targets encountered on the battlefield. It is superior in range accuracy and hit probability to the 90 mm recoilless rifle that it is intended to replace.

Aiming the Dragon missile from cover



Dragon missile

Dragon fired by gunner standing in the hatch of an APC during Engineering Tests in 1972

Dragon employs a command-to-line-of-sight guidance system and consists of three main items; a tracker, a recoilless launcher and a missile. The tracker includes a telescope for the gunner to sight the target, a sensor device and an electronics package. The tracker is reusable and is attached to the launcher, the missile is never seen by the gunner and after firing the launcher is discarded.

The missile is ejected from the tube by a gas generator using a recoilless technique. When it emerges folding fins flip open and the missile starts to roll. Thereafter propulsion is provided by the 60 small sustainers which fire in pairs on demand from the tracker. In operation, the gunner sights the target through the telescopic sight, then launches the missile. While he holds his sight on the target, the tracker senses the missile position relative to the gunner's line of sight and sends command signals over wire to the missile.

As commands are sent continually to the missile, the side thrusters apply corrective control forces. The thrusters are fired at appropriate roll angles so that the missile is automatically guided throughout its flight.

CHARACTERISTICS:

Designation: M-47
Type: Anti-tank guided missile
Guidance: Wire-guided, command to line of sight
Propulsion: Recoilless launched, solid-propellant rocket motor
Warhead: High explosive
Launch Weight: 12.25 kg
Range: 1 km

DEVELOPMENT:

Award to McDonnell Douglas of a $133 million contract for production engineering and production of Dragon was announced on June 28, 1968. The US Army announced in February 1970, however, that the missile would require further testing and would continue in development until June 1971.

The first manned firing of a Dragon armed with a live warhead took place at Redstone Arsenal on January 21st, 1971.

STATUS:

A small production test quantity of 560 missiles and 28 trackers was purchased by the Army in FY 1972 and in FY 1973 missile procurement was 3950. Purchases and supplementary requests for FY 1974 covered 7,000 missiles and for FY 1975 15,200 missiles and 1,200 trackers have been requested for the Army and 1378 missiles and 158 trackers for the USMC. 300 night sights have also been requested for the Army.

MANUFACTURER:

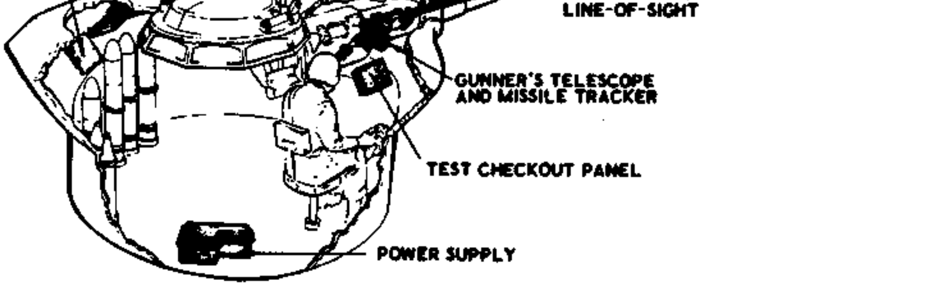
McDonnell Douglas Astronautics Co, TiCo Plant, Titusville, Florida.

2809.111
SHILLELAGH CLOSE SUPPORT WEAPON SYSTEM

DESCRIPTION:

Shillelagh is a lightweight close-support army guided weapon system intended primarily for use in a ground-to-ground role but suitable also for air-to-surface launching from helicopters. It is a direct-fire missile which can be carried by a variety of land vehicles ranging from armoured reconnaissance vehicles to main battle tanks.

Shillelagh is capable of high accuracy against both stationary and moving targets. The missile is fired from a 152 mm dual-purpose gun and missile launcher which also can fire conventional ammunition. Shillelagh is fired by a gunner, who guides the missile to its target using an infra-red command guidance system. He merely points the cross hairs at the target and follows the target during the missile flight to the point of impact. A missile tracker associated with the gunner's telescope measures the deviation of the missile's flight path from the line of sight, and the resultant



General arrangement of Shillelagh missile guidance system signals are converted into commands that are transmitted by the infra-red transmitter to the missile receiver. Here the commands are translated into actuation signals for the jet reaction flight controls. The missile is fitted with flip-out fins which open when it leaves the launcher.

CHARACTERISTICS:

Type: Lightweight land-mobile surface-to-surface guided weapon system

Guidance Principle: Infra-red command guidance to gunner's line of sight

Guidance Method: Hot-gas jet reaction

Propulsion: Cannon launch. Single-stage solid-propellant sustainer (Amoco Chemicals)

Warhead: Octol shaped charge

Missile Length: 1.14 metres

Missile Diameter: 152 mm

Launch Weight: 27 kg

DEVELOPMENT HISTORY:

The initial research and development contract was awarded to the Aeronutronic Division of Philco Ford by the US Army in 1959 following an industry-wide competition. The weapon system is managed by the US Army Missile Command, Redstone Arsenal, Alabama; and other government agencies have provided development support for specific components such as the warhead, fusing, propellants and optics.

Successful tests were carried out at White Sands Missile Range, New Mexico, in Arctic conditions in Alaska and in tropical conditions in Panama.

Limited production began in 1964; first production deliveries were made to the US Army in 1966; and the system was first deployed in 1967. Since then it has been made in larger numbers than any previous US guided missile. Philco-Ford Corporation received a $34.1 million production contract in September 1969.

Shillelagh is the main armament of the General Sheridan lightweight, air-transportable armoured reconnaissance vehicle, forming the Sheridan/Shillelagh weapon complex; it has also been adapted to an advanced version of the US Army's M60 Main Battle Tank – the M60 A2 (**5025.102**). It was also specified for the joint American-German MBT-70 Main Battle Tank (**5029.102** but see **2853.102**) development of which was cancelled.

The gun-launcher used in the M60 A2 differs from that used in the Sheridan. Sheridan gunners speak highly of the Shillelagh missile, which they find easy to use, but firing the conventional round, which has a fully-combustible cartridge, has been said to be less than satisfactory in the Sheridan – partly, no doubt, because it is lightly constructed for firing so large a weapon. It is said, however, that in the M60 A2 – as finally developed – the gun can be used more satisfactorily and with greater reliability and maintainability than in the Sheridan, while the Shillelagh performance is unimpaired.

For helicopter-launching in its air-to-surface role Shillelagh is used in conjunction with a gyro-stabilised sight, also developed by Aeronutronic.

STATUS

The first procurement of Shillelagh was completed in 1970. In January 1972, however, the manufacturers announced receipt of a contract for nearly $12 million for modifications to the system. Details of these modifications have not been made public but they were said to affect both the missile itself and its guidance and control equipment.

2830.111
TOW ANTI-TANK MISSILE

DESCRIPTION:

TOW is an acronym for Tube-launched, Optically-tracked, Wire-guided, and describes a heavy assault ground-to-ground (or air-to-ground) anti-tank guided weapon system.

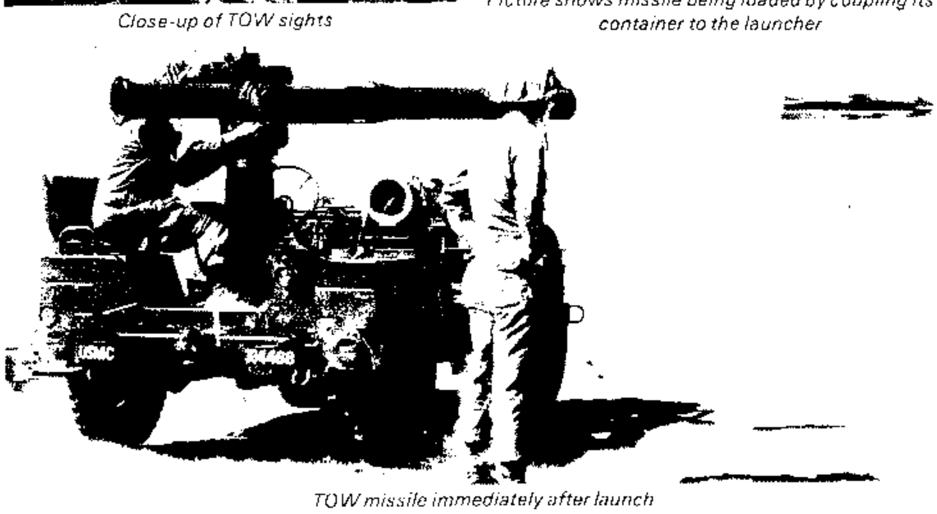
The TOW launcher system, for infantry use, is made up of five elements none of which weighs more than 24 kg, although the complete launcher weighs 78 kg when assembled and ready to fire. Four of these elements are a tripod and a traversing unit, mounted upon the tripod, to which the tripod launch tube and optical sight are attached. The gunner's optical sight is of high magnification and equipped with aiming cross-hairs which when combined with the smooth, stable motion of the traversing unit permit very accurate tracking of moving targets after very little operator training. The fifth individual element is the electronic guidance computer which sends steering commands automatically to the missile in flight.

The missile itself is contained in a sealed storage and transport container which becomes a launch tube extension when placed in the launcher breech. After the breech locks, all electronic contacts to the missile are automatically closed, and TOW is ready to fire.

The missile contains two solid propellant motors. The launch motor ejects the missile from the launch tube and is burned out by the time the missile has left the tube. Only after the missile has flown several metres does the flight motor ignite, so that no protection is necessary for the gunner against hot exhaust gas and propellant particles. The flight motor is mounted in the centre of the missile with its two exhaust nozzles mounted on either side. This arrangement prevents interference with the guidance wires which are placed at the tail of the fuselage. Steering commands are transmitted by the two wires which uncoil from two separate spools. Cruciform, short wings in the

Close-up of TOW sights

TOW heavy anti-tank guided weapon system. Picture shows missile being loaded by coupling its container to the launcher



TOW missile immediately after launch

centre of the missile and the cruciform rudder surfaces all unfold after leaving the launch tube. Missile manoeuvring is done entirely aerodynamically (without jet vanes) so that TOW maintains good manoeuvrability throughout missile flight. The electronics unit is mounted between the flight motor and the armour-piercing warhead

The flight motor accelerates the missile rapidly to its peak velocity and then burns out so that TOW leaves no visible smoke trail, which could allow an enemy to trace the flight path back to the place of launching. In addition, the missile does not continue to leave a heat trail which could interfere with tracking or the use of a night sight. Owing to the high initial speed a target once detected can quickly be engaged and a high rate of fire is possible. Due to its use of aerodynamic control, the TOW manoeuvre capability gives it a very low minimum firing range and at this short range targets can be engaged effectively even though they may be crossing at speeds of up to 50 km/h.

The anti-tank warhead has been designed to penetrate the armour plate of all types of tanks known or expected in the planned life of the system. It has also been shown to be effective against concrete bunkers and similar fortifications.

After the missile leaves the launch tube, a light source in the tail comes on so that the optical sensor on the launcher, which is bore-sighted with the gunner's telescope, can track the missile along its flight path. The light source does not distract the gunner, and it is sufficiently strong to allow automatic guidance to the maximum range of the missile under all conditions in which the target is visible to the gunner.

OPERATION:

The gunner's only job is to keep the cross-hairs of his telescope on the target during missile flight. The light source in the missile is tracked by the sensor which measures the angle between the flight direction of the missile and the gunner's line of sight. These displacements are transformed by the computer into guidance commands for the missile.

MOBILE INSTALLATIONS:

TOW can also be installed in most of the available wheeled or tracked vehicles capable of cross-country travel. The US Army is using it on armoured personnel carriers, jeeps and UH-1B and AH-1G HueyCobra helicopters; the US Marine Corps has tested it on the "mechanical mule". Moreover, the American Army plans to operate the system on more advanced armoured vehicles similar to the German Schutzenpanzer.

The adaptability of TOW for the armament of fighting helicopters has been thoroughly demonstrated. Missiles can be fired even at high speeds and still hit the target, and during an attack the helicopter can fly evasive manoeuvres. The missile was used in this role with considerable success in Vietnam; and in manoeuvres in Germany in 1972 the possibility of destroying as many as 20 tanks for every helicopter lost was demonstrated (see **2831.311**).

TOW mounted on the FMC XR311 high-mobility wheeled vehicle

CHARACTERISTICS:

Military Designation: BGM-71A

Type: Heavy anti-tank guided weapon system

Guidance Principle: Automatic missile tracking and command guidance from optical target tracker

Guidance Method: Wire guidance control of gas-operated aerodynamic tail surfaces

Propulsion: Two-stage solid-propellant motor. First stage quadruple; second stage single. Recoilless launch

Warhead: High-explosive shaped charge armour piercing

Missile Length: 117 cm

Missile Diameter: 15.2 cm

Launch Weight: 18 kg

System Weight: 102 kg including one missile

Speed: Believed to be at least 1,000 km/h

Range: Minimum: 65 metres
Maximum: 3,000 metres

Rate of fire: 3 launches in 90 sec

Crew: 4

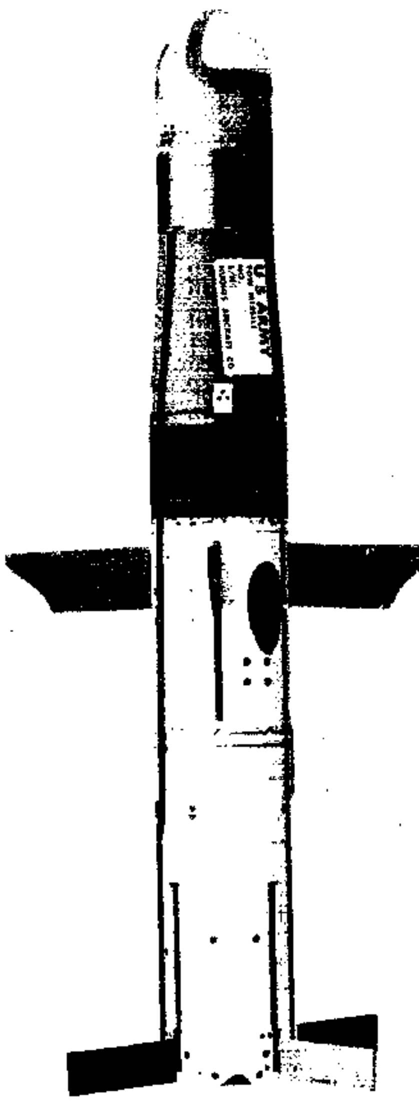
DEVELOPMENT:

The system has been under development since 1962, when the Hughes Aircraft Company won a competition with several other defence contractors.

TOW production missile firings began in August 1969, and by February 1970 more than 75 missiles had been expended.

STATUS:

TOW is in full production for the US Army. \$62.7 million was authorised for procurement in FY 1972 and \$43.3 million was spent in FY 1973 when 12,000 missiles were bought. Initial and supplementary requests for FY 1974 covered 23,425 missiles and 1618 launchers (including an initial quantity of both for the USMC) and totalled \$153.8 million (including spares and RDT&E expenditure) and \$138.4 million was requested for FY 1975 to cover the purchase of 30,319 missiles and 1041 launchers as well as providing the comparatively large sum of \$10.7 million for RDT&E.



THE TOW missile

TOW has also been sold to Italy, West Germany, Iran and the Netherlands and is one of three missiles being considered by the British Army for helicopter-launched applications – the other two being HOT and Airstrike Swingfire (**1654.311**).

MANUFACTURERS:

Hughes Aircraft Company, Culver City, California, is the prime contractor for the system having developed it for the US Army Missile Command.

Emerson Electric Co, Electronics and Space Division, 8100 Florissant, St Louis, Missouri 63136, are prime suppliers of the launcher, missile guidance set, optical sight and traversing unit.

2838.111

TERMINALLY GUIDED SUB-MISSILE (TGSM)

DESCRIPTION:

Conceived originally as a means of extending the range of operational applications of the Lance battlefield support missile (**2682.111**) the terminally-guided sub-missile (TGSM) is an anti-armour weapon which could be used in conjunction with any ballistic or quasi-ballistic launch vehicle having a comparable or higher apogee and range.

Whereas most other anti-tank weapons are line-of-sight weapons, the TGSM offers an indirect-fire option to a force commander, enabling him to engage reinforcements to the rear of enemy formations.

As the system is at present envisaged, six or nine TGSM would be loaded into the warhead compartment of a missile which would then be fired in the direction of a group of armoured vehicles or similar target located by reconnaissance. The warhead compartment has an ogive-shaped steel casing and is furnished with linear explosive charges which, at a predetermined time after the carrier missile has passed its apogee, cut the shell longitudinally and circumferentially. The resulting casing segments, as they move outwards and are decelerated by air resistance, eject the sub-missiles laterally to give the required dispersion.

The TGSM are equipped with timing devices which begin to operate on ejection: at the same time the covers over the rear ends of the sub-missiles are blown clear, drawing a paraballoon out of the aft end of each missile. This paraballoon stabilises the flight of the sub-missile. After a preset interval the timer opens two fixed and two movable tail fins from slots in the rear casing of the missile, at the same time detaching the paraballoon and activating the search mechanism of the sub-missile's guidance system.

This search mechanism scans the ground until the required target is identified – the dispersion of the sub-missiles being planned to keep to an acceptably low level the chance that more than one TGSM will lock on the same target. When the target is acquired, the guidance system locks to it and guides the sub-missile in unpowered flight using the moveable tail fins for control. If the control is inadequate to guide the weapon to the target the search mechanism is re-activated to seek another target. This is a relatively undesirable sequence of events, however, and the general aim would be to release the sub-missiles high enough to provide adequate time and energy for manoeuvre but not so high that target acquisition became difficult.

The target acquisition system is likely to use an infra-red detector tuned to the typical emission spectrum of armoured vehicles. It is understood, however, that a millimetre-band radiometric correlator is also being considered – the latter having the advantage of being less affected by environmental conditions than an IR system.

Although primarily designed as an anti-armour device the TGSM could evidently be used for other purposes – provided the target was of a kind that could be identified by a suitably small seeker head.

CHARACTERISTICS:

Type: Unpowered, missile-launched, guided anti-armour missile

Guidance Principle: Passive, selective IR or millimetre radiometric correlation homing

Guidance Method: Control of aerodynamic tail surfaces

Propulsion: Propulsive energy supplied by carrier

Warhead: HE anti-armour. Other warheads possible

Missile Dimensions: Length 76 cm; diameter 15 cm; span 46 cm; weight about 15 kg

Range: Dependent on carrier. Up to about 160 km with Lance missile

STATUS:

Development. Ejection and allied processes have been satisfactorily demonstrated using a rocket-sledge, and homing and guidance systems have been tested by dropping missiles from helicopters. Full-scale testing is believed to be imminent at the time of writing. Possible deployment date – given adequate financial support – is thought to be 1978

MANUFACTURER:

THE UNION OF SOVIET SOCIALIST REPUBLICS

2983.111
AT-1 (SNAPPER) ANTI-TANK MISSILE

DESCRIPTION:

Snapper is the NATO code name for the wire-guided anti-tank missile believed to be known to the Russians as Shmell (Bumblebee) or 3M6 and known also by the US code AT-1. It is a vehicle-borne system, now usually deployed on the BRDM armoured amphibious vehicle, and is similar in general configuration to such missiles as the MBB Cobra and Contraves-Oerlikon Mosquito.

The missile is launched from a guide rail, a triple mounting being standard in the BRDM vehicle, whereas quadruple mountings were used on the GAZ-69 light cross-country vehicle on which the missile was formerly deployed. The triple mounting is retractable, the weapons being transported under cover plates which open up for firing. There is also a ground launcher for infantry use.

Provided with periscope binoculars embodying an illuminated variable-brightness reticle with which to sight the target, the operator uses a joystick to control the missile, keeping it on the line of sight to the target with the aid of tracking flares on two of the wings. The missile can be fired and guided by an operator stationed anywhere up to 50 metres from the launcher.

Multiple launcher for Snapper anti-tank missiles

CHARACTERISTICS:

Type: Surface-to-surface guided anti-tank missile

Guidance Principle: Wire-guided, command to line-of-sight; optical tracking

Guidance Method: By control of vibrating trailing-edge spoilers

Propulsion: Solid-propellant rocket motor

Warhead: Hollow charge

Missile Length: 1.13 metres

Missile Diameter: 14 cm

Launch Weight: 22.25 kg

Cruising Speed: 320 km/h

Range: 500-2,300 metres

STATUS:

In service with Warsaw Pact countries and in Cuba and the United Arab Republic

2985.111
AT-2 (SWATTER) ANTI-TANK MISSILE

DESCRIPTION:

Swatter is the NATO code name for a wire-guided anti-tank missile which is known as the AT-2 in the US code and which, like the AT-1 (**2983.111**), is carried on the BRDM armoured amphibious vehicle.

Of similar size to the AT-1 it is believed to be a more advanced missile – probably in the class of the French SS.11 – and certainly has a different configuration. Control is by elevons mounted on the trailing edges of the rear-mounted cruciform wings.

The standard mount on the BRDM vehicle carries four missiles mounted on guides. Operation of the missile is presumed to be similar to that for the AT-1, except that the missile appears to have some form of terminal guidance system – believed to be an infra-red homing device – mounted in the nose.

Range is believed to be 2,500 m; propulsion is by solid propellant motor; missile length is 114 cm and diameter is 132 cm

STATUS:

Believed to be in service only with Warsaw Pact forces.

BRDM I showing the mounting arrangements for the four Swatter anti-tank missiles (Tass)

2950.111
AT-3 (SAGGER) ANTI-TANK MISSILE

DESCRIPTION:

Sagger is the NATO code name for a small wire-guided anti-tank missile, also known by the US code AT-3 and, first seen in the VE-Day anniversary parade in Moscow in 1965. More compact than either the AT-1 (Snapper) or AT-2 (Swatter) missiles (**2983.111** and **2985.111**), but apparently carrying an equally powerful warhead, it is known to be deployed in various vehicle mountings including a 2 × 3 mounting on the BRDM-1 amphibious reconnaissance car (**5034.102**) and a single mount on the BMP-76PB armoured personnel carrier (**5054.102**). There is also a single manpack mounting that enables it to be fired from the ground.

In the BRDM vehicle the two clusters of three

This close-up of the BMP-76PB mounting shows clearly the short launch rail of the AT-3 missile

Sagger anti-tank missiles mounted on BMP-76PB armoured personnel carriers seen in the Moscoow parade in November 1967 (Novosti)

missiles are mounted retractably and are shielded when in the firing position by the cover plate that protects them when in the retracted position.

Like the two earlier missiles, the AT-3 is powered by a solid-propellant rocket motor.

CHARACTERISTICS:

Type: Surface-to-surface guided anti-tank missile
Guidance: Wire-guided; command to line of sight; optical tracking
Propulsion: Solid propellant motor
Warhead: Hollow charge C. 3 kg
Missile Length: About 70 cm
Missile Diameter: About 12 cm
Range: 2.5 km
Penetration: 400 mm

STATUS:

Formerly believed to have been used only by Warsaw Pact forces, the AT-3 is now in service in the Middle East and was extensively used against Israeli tanks in 1973. Reports indicate that it is an effective weapon.

BATTLEFIELD SUPPORT WEAPONS

2285.111
INTRODUCTION

This section is concerned primarily with large land-mobile tactical guided missiles designed for use as super-heavy artillery over ranges from a few tens to several hundreds of kilometres and many of them equipped with nuclear warheads.

Such missiles, however, are not the only land-based tactical nuclear weapons that are available to the commanders of the armed forces of major military powers: conversely, the guided missiles themselves are not necessarily equipped with nuclear warheads – although their cost-effectiveness if equipped only with HE warheads is open to question.

A few brief notes on the main categories of land-based tactical nuclear weapons may help the reader to identify and locate the weapons which are of interest to him.

Tactical Ballistic Missiles – Guided

Described in this section, these are all substantial ramp-launched rocket-propelled weapons almost all of which have been designed from the outset to be armed with nuclear warheads but most of which have an alternative HE warhead. They are sometimes referred to as short-range ballistic missiles (SRBM) to distinguish them from the longer-range strategic missiles.

Most of these weapons are inertially guided; but the early versions of the Russian Scud missiles (**2969.111**) are believed to have used radio command guidance and it is believed that one of the missiles developed in Egypt (**2050.111**) was wire-guided.

Almost all the missiles of this type that are known to have been developed are either American or Russian: the only other weapon that is known to have been completely developed is the French Pluton (**2130.111**). A British development programme, for a missile known as Blue Water, was cancelled – but on political/econommic grounds: technically it was considered by some to be superior to the American Sergeant missile (**2804.111**). Notwithstanding claims, suggesting the contrary, that were made during the 1973 Arab-Israeli war the German-aided missile development programme in Egypt (**2050.111**) never resulted in significant deployment of operational missiles. The situation regarding the Israeli Jericho missile (**2226.111**) is far from clear. We have received no information on Chinese People's Republic developments in this field but clearly they could develop weapons of this kind if they wished to do so. A battlefield support missile is, however, reported to be in an exploratory development phase in Taiwan.

Tactical Ballistic Missiles – Unguided

Missiles of this type, though still quite widely deployed, must be regarded as obsolescent at least. Weapons believed to be still in use are the American Honest John (**2652.113**) and most of the Russian Frog missiles (**2920.113** etc). In earlier editions of this book these missiles were described in this section; but recent developments have tended to blur the distinction between these weapons and other unguided artillery rockets and to accentuate the importance of the distinction between the guided and unguided types of weapon: the descriptions are therefore now to be found, with those of the other land-based unguided artillery rockets, in Section Three.

Tactical Cruise Missiles

Although several types of guided tactical cruise missile have been developed since the end of the Second World War, the only ones currently deployed as battlefield support weapons are of Russian origin and are described in this section. Weapons believed to be identical to these are also available for use for coastal defence; but since several other weapons, not used for battlefield support, are also available for coastal use a separate section, following this one, is devoted to such weapons.

Interest in the use of remotely piloted vehicles for military purposes, which has waxed and waned several times since such remote control became a practical possibility, is currently on the increase. It will not be surprising, therefore, if other countries introduce either nuclear or non-nuclear RPVs for battlefield support. An early example is quite likely to come from the USA: emphasis there is currently on air-launched and submarine-launched strategic or tactical cruise missiles, but much of the development work would be relevant if a land-based missile were required.

Heavy Tube Artillery

Both the USA and the USSR have operational large-calibre artillery weapons which can fire nuclear ammunition with kiloton-range yields. The American weapons – such as the M-110 203 mm SP howitzer (**5523.103**) and the M-109 155 mm SP howitzer (**5508.103**) and variants – are in service in several other NATO armies and a few non-NATO armies. Few, if any, of the weapons in non-American forces have nuclear ammunition available to them, however, and any such ammunition is in the custody of US forces. So far as is known, neither Britain nor France has yet developed nuclear shells for artillery weapons although both have the ability to do so: the British Army uses American nuclear-capable weapons and France has weapons of similar calibre (see especially **5574.103**).

Ammunition for the Russian M-55 203 mm gun-howitzer (**5540.103**) is believed to be controlled in much the same way as is the nuclear ammunition for the American weapons. Some of the M-55 weapons, however, were supplied to the Chinese People's Republic some years ago, and it is conceivable (though perhaps unlikely at the present time) that nuclear ammunition has been developed for them in China.

Since these heavy weapons, even when firing nuclear ammunition, are controlled and operated in the same way as other tube artillery they are not described in this section. Available details can be found in Section 3.

Miniature Nuclear Warheads

Classification of battlefield support weapons has been complicated by the emergence of the miniature low-yield nuclear warheads to which development effort has been applied recently in the USA and possibly elsewhere. The possibility of equipping a shell or rocket warhead with a physically small nuclear charge having a yield of, say, 0.1 KT considerably modifies the potential tactical significance of many bombardment weapons of quite modest size; and the allied possibility of equipping larger missiles with several of these devices, with or without terminal guidance, could in certain circumstances reduce the need for basic missile accuracy and would in any event give grounds for re-classifying some unguided rocket weapons as weapon *systems*.

For the time being, however, since deployment of these miniature nuclear weapons is not expected - in Western forces at least - before about 1978, discussion of them is limited to a few details in entry **2725.103** in Section 3. Multiple warheads, specifically related to the Lance missile system (**2682.111**) are discussed in the previous section (**2838.111**) and reference should also be made to the Pave Pepper programme (**2839.111**) which may relate to both strategic and tactical missiles.

Rocket Assisted Projectiles (RAP)

Rocket-assisted unguided projectiles for field artillery weapons have been available to the US forces for some time and are described in Section 3 (**2834.103** and see also **6091.203** for naval applications). A note on guided projectiles is included in this section (**2837.111**). The techniques involved could be applied to nuclear ammunition but it is believed that they have not

Static Nuclear Weapons

In addition to the various rockets, shells and other missiles which can be used in nuclear warfare there exist many nuclear devices which are designed for use in a static role to hold up an enemy advance or otherwise deny territory to him. Details of such devices are not available; but their general nature and principle of operation is sufficiently obvious for further discussion here to be unnecessary.

EGYPT

2288.111
BATTLEFIELD SUPPORT MISSILES (1973)

During the 1973 Arab-Israeli war, President Sadat of Egypt was reported to have threatened to attack Israeli cities with a long-range missile which he is said to have described as the Zafir.

Dating back to about 1961 there was a programme of missile development in Egypt, in which German scientists and engineers are believed to have been involved, which resulted in the creation of three rockets. Two of these were single-stage missiles, the smaller called Al Zafir and the larger Al Kahir, and the third was a two-stage rocket (Al Raid) which may or may not have been intended for military purposes. Brief descriptions of these rockets - which were first seen in public in 1962 - were last published by us in the 1972-73 edition (**2050.111**).

So far as is known, the three projects were dropped, briefly revived and then finally abandoned in the middle to late 1960s. The reason for abandoning them is believed to have been failure to develop a reliable guidance system, and because of this it seems most unlikely that President Sadat's threat was backed by *Egyptian* missiles, although what is believed to have been the design performance of the original Al Zafir (500 kg warhead and 375 km range) would have been reasonable in the context.

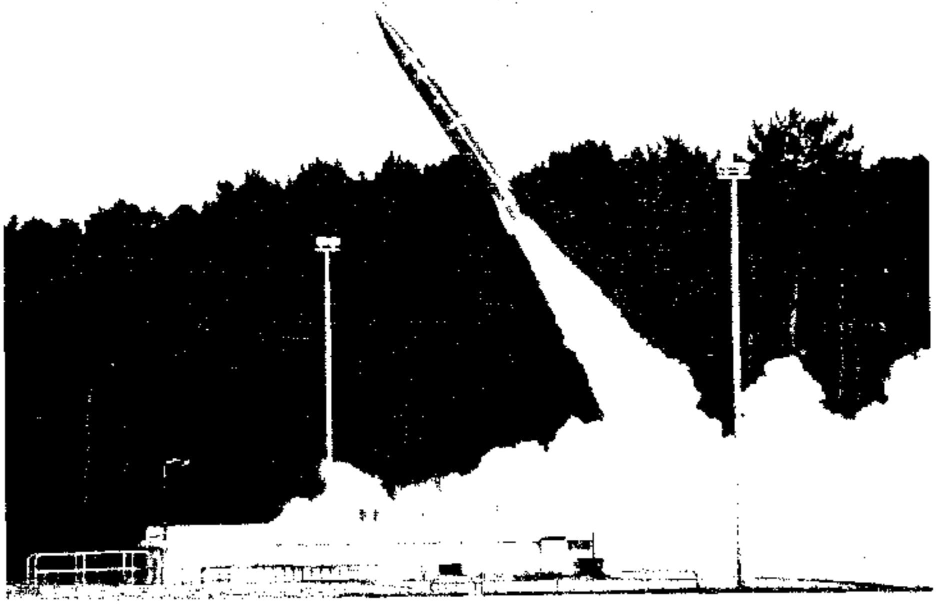
On the other hand US reconnaissance reports revealed the presence in Egypt at that time of a quantity of Russian Scud missiles (**2969-70.111**) complete with nuclear warheads: and while it is probable that such dangerous weapons would have remained effectively in Russian custody in one way or another it could well be that it was their presence in Egypt that prompted President Sadat to issue his threat.

FRANCE

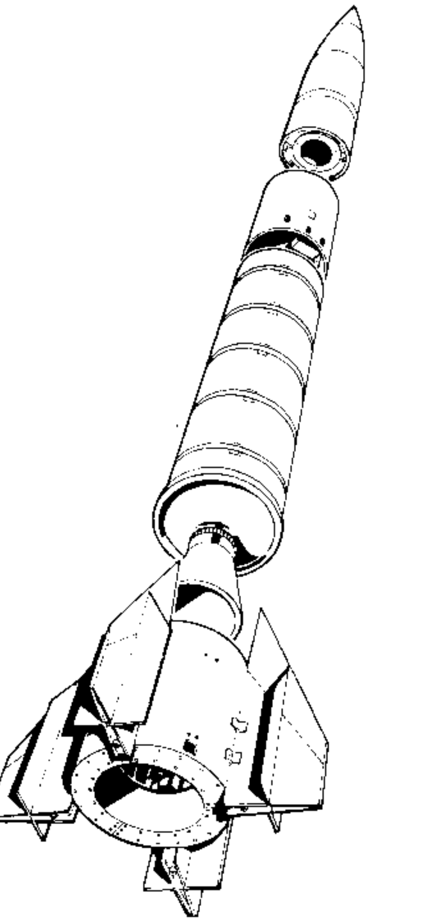
2130.111
PLUTON BATTLEFIELD SUPPORT MISSILE

Description

Developed to meet a French Army requirement, Pluton is a surface-to-surface tactical nuclear missile. The weapon, which is intended to have a range capability from 10-120 km, is installed on and fired from the AMX-30 tank chassis, the missile container being used as a launching ramp.



Launch of Pluton missile



Main components of Pluton missile

Missile and warhead are supplied separately to operational units.

In addition to the AMX-30 launching vehicle the system includes command vehicles containing data processing equipment organised round the IRIS 35M computer of the Plan Calcul Militaire. This is a third-generation general purpose computer capable of operation under severe environmental conditions. If operational circumstances require it, target data can be obtained in real time from an R.20 drone (**2127.351**) equipped with a Cyclope passive IR reconnaissance system (**1070.353**). Missile guidance is by means of a simplified inertial system based on a SFENA stable platform. The warhead is the AN-52 tactical nuclear weapon which is also used for air-dropped bombs. It has a yield of 10-15 kilotons.

Characteristics

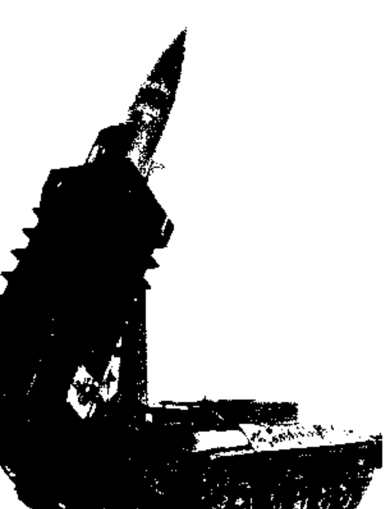
Type: Land mobile, vehicle-launched, tactical nuclear weapon system

Guidance: Inertial

Propulsion: Dual thrust solid propellant rocket motor. Propellant weight 1,200 kg

Warhead: Nuclear: reputedly 10-15 kilotons

Missile Length: 7.7 metres



Pluton missile on launcher vehicle

Body Diameter: 63 cm
Span: 141 cm
Launch Weight: 2,400 kg
Range: 10-120 km
CEP: Believed to be 200-400 m depending on range
Crew (Launch Vehicle): 4

STATUS:

Test firings have been carried out. Initial production contracts were awarded in 1972, and deliveries to the French Armed Forces began early in 1974. The last reported order quantity was 120 missiles, and it is believed that the initial deployment will be of six regiments, each armed with six missiles, with the French 1st Army. Army evaluation firings began late in 1972.

It was at one time thought that the French authorities had no intention of exporting Pluton. Recent comments in the French press concerning the purchase of Lance (**2682.111**) by European nations, however, suggest that the French missile is in fact on offer. There is, however, no official confirmation of this.

DESIGN AUTHORITIES:

Programme direction: Direction Technique des Engins.

Nuclear Warhead: Commissariat à l'Energie Atomique.

Command and Control System: Direction Technique des Armements Terrestres.

MANUFACTURERS:

Project management, aerodynamic studies, structure, guidance and control system: Aérospatiale, 37 Boulevard de Montmorency, 75016 Paris, France. Others involved are –

Rocket Motor: SEP

Propellants: SNPE

Main Body Equipment: SFENA, Air-Equipment, Auxilec

Warhead Equipment: SERAT

Crane: Griffet

Turbine: Microturbo

Vehicle Equipment: CII, CIT, SINTRA, SOPELEM

Vehicle Integration: DTAT / GIAT

Command Antenna: SPAIR

Command & Control Equipment: CII (Computer), CIT, SINTRA

Command & Control Integration: DTAT / SEFT

ISRAEL

2226.111
ISRAELI BATTLEFIELD SUPPORT MISSILES

DESCRIPTION:

There have been persistent reports in recent years that Israel has one or more surface-to-surface weapons programmes under way.

One of these relates to a missile known as Jericho, another relates to a two-stage surface-to-surface rocket whose project reference is MD 660. The two programmes may well be one and the same thing; and indeed the only reason for supposing that they may not be is an earlier association of the name "Jericho" with an earlier number, MD-620.

So far as is known, the Israelis have at no time in the recent past admitted that either project still exists as a current venture, indeed, at and around the time of the 1973 Arab-Israeli war reporters were firmly told that no such project existed. These denials have to be viewed in the context of a threatened attack by Russian Scud missiles based in Egypt, however – circumstances of a kind in which most people would argue that some distortion of the truth would be permissible.

While not denying the Israeli denials, therefore, we think it right to record what has been said about the Jericho project in other quarters. According to the reports referred to above the MD-660 is fired from a mobile ramp and is said to have a design range of 450 km. The warhead can be high-explosive or nuclear – the nuclear warheads being made in Israel.

STATUS:

MD-660 programme history extends back over several years and that of the MD-620 programme even longer. Nevertheless it is not definitely known that the Jericho or any similar programme exists: nor is it known, even if the programme does exist, that nuclear warheads could or would be made available for use with the missiles.

MANUFACTURER:

Not known – but it is known that Dassault were involved in the early days prior to the arms embargo. There is, however, certainly no French involvement now.

THE UNITED STATES OF AMERICA

2682.111
LANCE BATTLEFIELD SUPPORT MISSILE

DESCRIPTION:

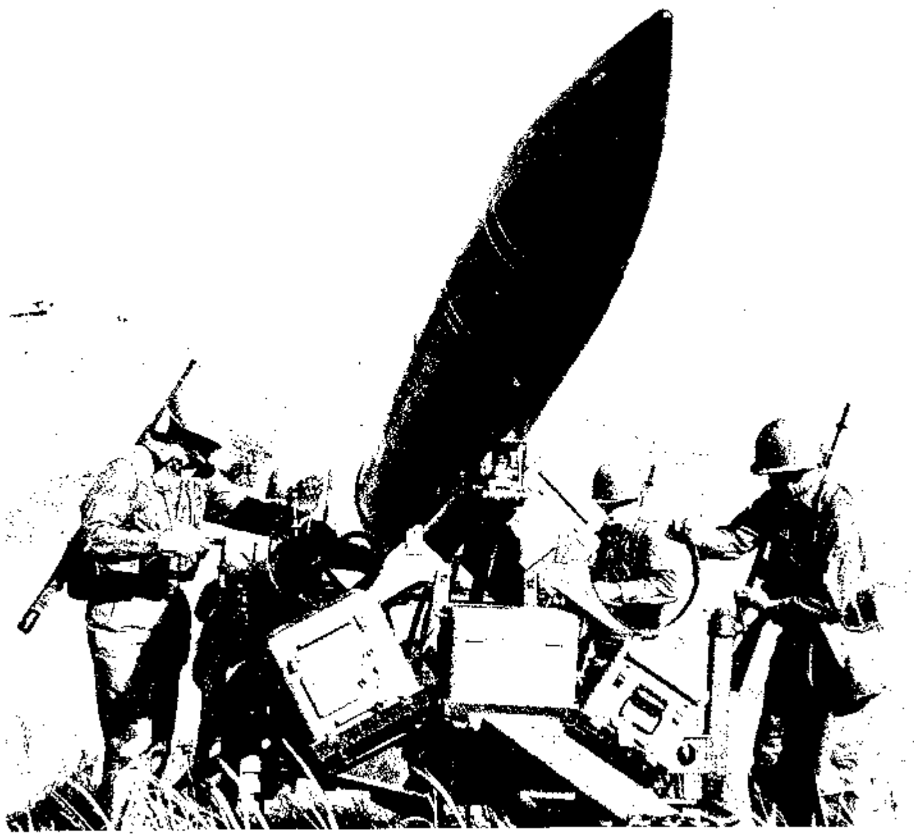
Lance is a surface-to-surface guided missile designed to provide general battlefield fire support for an Army corps. It will replace both Honest John and Sergeant missiles. It can carry either a nuclear or conventional high-explosive warhead and its range has been estimated at approximately 110 km. It requires a six-man crew, half the number required for Honest John (**2652.111**) and Sergeant (**2940.111**).

This highly mobile missile can be delivered by plane or it can be airdropped. It also has a good mobility over ground and can swim inland waterways. Lance uses simplified inertial guidance, and is the first US Army missile to use ready-packaged and storable liquid propellants. Major ground support equipment includes a self-propelled launcher, a fully mobile lightweight launcher and a transporter-loader.

In the field, Lance will complement conventional divisional tube artillery and extend the resources for nuclear or non-nuclear supporting fire available to the divisional commander.

The Lance missile comprises a warhead section, a guidance package, fuel tankage and an engine. The guidance package is a rugged low-cost device conceived and developed in the US Army Missile Command's Guidance and Control Laboratory. Over the operational range of the missile it is claimed to have a high degree of accuracy and reliability.

Spin-stabilisation in flight is achieved initially by venting some of the propellant gases through canted vents in the body of the missile. After initial spin has been imparted in this way it is maintained



Lance on its lightweight launcher

by aerodynamic pressure on the canted fins at the base of the missile.

Propulsion is by a Rocketdyne storable liquid-propellant engine comprising two concentrically-mounted sections. The outer section provides thrust during the boost phase of the missile's flight, and during this phase, which corresponds to a flight of about a mile (1,600 m), the missile is under tight control by the control and guidance electronics. When the on-board inertial system detects that the predetermined velocity has been achieved, the boost motor is extinguished and the missile continues on a zero-g flight powered by the (inner) sustainer motor. At a predetermined point in the flight this motor, too, cuts out, and the missile finishes its journey in free flight.

For land-mobile operations the weapon system will be transported on two XM-667 vehicles (US Army's M-113 family of tracked vehicles) one of which will function as an erector-launcher while the other carries two extra missiles and a loading hoist. For air mobile operations the lightweight launcher will be more appropriate; and this and the missile can be taken into the battle zone by helicopter or parachuted from a fixed-wing aircraft.

CHARACTERISTICS:

Designation: MGM-52A

Type: Mobile surface-to-surface tactical guided missile

Guidance: Simplified inertial

Propulsion: Two-part, concentric pre-packed storable liquid-propellant motor

Warhead: Nuclear or high-explosive

Length: Approx 6 metres.

Diameter: Approx 55 cm

Launch Weight: Approx 1,500 kg

Speed: Supersonic

Range: Estimated 110 km

DEVELOPMENT:

The Lance prime contractor was selected in 1962. The research and development contract was awarded in January, 1963. The first test firing was made at White Sands Missile Range in March 1965. The first firing from the engineering model lightweight launcher was in July 1965; and first firing from the self-propelled launch vehicle came the following month. In October of the same year the first successful parachute drop was made. Ground testing was begun in March 1966 at Redstone Arsenal, Alabama. The missile was fired successfully in temperatures of 140 degrees and 40 degrees below zero in 1969. Thirty-seven static tests and six flight tests were conducted in 1969.

Lance development was delayed for approximately one year when problems were encountered with the propulsion system and the rocket engine, but these difficulties were subsequently overcome. The first production model was delivered to the US Army for service testing in April 1971; the first Army launch took place that August and service testing was completed in March 1972.

During development a total of 156 flight tests were conducted – including 37 Army launches, all but one of which were successful.

STATUS:

Lance was type-classified "Standard A" early in 1972 and the first training battalion was activated in April. The weapons are now replacing Honest John (**2652.103**) and Sergeant (**2804.111**) units and it now seems likely that replacement in US service will be completed in 1975. The first operational launch took place in November 1972. It is expected that Lance will also be bought at least by those of the Eurogroup of NATO who currently have either Honest John or Sergeant missiles. The value of this European purchase has been estimated at £250 million.

The standard A release relates only to the system with a nuclear warhead. To extend the range of tactical applications of the weapons the US Army wish to have a non-nuclear warhead also: this would employ a USAF cluster bomb and would be used against softer targets than those for which the nuclear warhead is required. Funds for this development were denied by Congress in FY 1972 and funds were not explicitly requested in the FY 1973 proposals. It was however thought possible that the Department of Defense might arrange to re-programme previously-authorised funds for this purpose.

LTV revealed, late in 1972, that they were studying a multiple warhead version of Lance; while this study was not explicitly concerned with the US Army proposals it was evident that the basic operational requirement was the same (see **2838.111** in the preceding sub-section).

A total of $85 million was included in the FY 1973 budget for the Lance system. Of that, $30 million was for 194 missiles less warheads and the balance was for warhead sections (excluding the nuclear device which is separately budgeted and procured from the Atomic Energy Commission) both for the US Army and for Lance systems "sold or expected to be sold" to NATO countries.

The budget for FY 1975 covers any study work done on the non-nuclear warhead but specifically excludes any procurement thereof.

2683.111
LANCE-DERIVED EXPERIMENTAL BATTLEFIELD MISSILE

DESCRIPTION:

This entry relates to an experimental project undertaken by LTV Aerospace – makers of the Lance missile (**2682.111**) – on behalf of the US Army Missile Command.

The purpose of the project is primarily to test and demonstrate in conjunction with Lance the use of a new low-cost missile guidance system, using fluidics instead of electronics, which has been developed by the US Army's Harry Diamond Laboratories.

A secondary objective is to demonstrate the use of a new low-cost solid-propellant propulsion system, developed for LTV by United Technology Centre, in place of the prepackaged storable liquid bi-propellant rocket motor now used in Lance.

It is expected that the demonstration missile will be less accurate than Lance; but it is believed that the inaccuracy will be almost entirely in range; the fluidic guidance system is expected to lead to minimal cross-track error. The range error is thought to be acceptable for applications in which Lance is used as an area weapon – eg with its single nuclear warhead or possibly with multiple warheads. It is unlikely, however, that the degree of error envisaged would be acceptable with the TGSM system (**2838.111**) although it may be possible to upgrade the accuracy of the new system later. The main advantage of the new guidance and propulsion systems will lie in cost reduction.

STATUS:

Experimental project on a $1.2 million contract from US Army Missile Command.

MANUFACTURER:

Michigan Division of LTV Aerospace Corporation, PO Box 5003, Dallas, Texas 75222.

2765.111
PERSHING 1A BATTLEFIELD SUPPORT MISSILE

DESCRIPTION:

Pershing 1A is an improved version of the Pershing 1 ground-to-ground guided weapon system (**2764.111**). It has replaced Pershing 1 and is now deployed with the US Army and the Federal German Republic.

The most obvious change that has taken place is the replacement of the XM-474 tracked vehicles on which Pershing 1 system components were mounted by a set of wheeled vehicles based on the M656 five-ton truck. The system now has an improved erector-launcher which is an articulated truck and trailer combination that carries both the missile and its warhead (previously carried on separate vehicles) and which is capable of both paved road and cross-country travel. The other vehicles are a transporter for the programmer-test and power stations, the firing battery control centre truck, and the radio terminal set vehicle with an inflatable antenna. All the equipment is transportable by the CS-130 cargo aircraft.

System reaction time of the Pershing 1A has been reduced below that of Pershing 1 by improvements in the erector-launcher and by the introduction of automatic countdown. The radio communications system has also been expanded. There is no change in the missile itself.

Most recent of the improvements is an Automatic Reference System (ARS) which employs gyro compass techniques similar to those used in navigation and which enables the missile to be fired from a previously unsurveyed site in something like half the time previously required for surveying.

DEVELOPMENT HISTORY:

A $66 million development contract was awarded to Martin Marietta in 1966. This was followed by two production contracts, one for $52 million in 1967 and one for $32 million in 1968. Production started in November 1967 and was completed in 1971.

Pershing 1A equipment began deployment with US and West German forces in Germany in the summer of 1969 and was completed in 1971.

CHARACTERISTICS:

Military Designation: MGM-31A

Type: Land-mobile air transportable surface-to-surface tactical ballistic missile system

Guidance: Inertial
Propulsion: Two-stage solid-propellant rocket motor
Warhead: Nuclear. The majority of deployed weapons are believed to be equipped with 400 KT warheads but some have lower yields – down, it is believed, to 60 KT
Missile Length: 10.5 metres (approx)
Missile Diameter: 1 metre (approx)
Launch Weight: About 4,600 kg
Speed: Mach 8
Range: 160-840 km

STATUS:

Operational. Funding requested for FY 1975 covered $7.9 million for 54 Automatic Reference Systems and $11.1 million for component replacements to prolong the operational life of the missiles. This replacement operation covers 88 missiles and is the final stage of a four-year modernisation programme.

MANUFACTURERS:

Complete System: Martin Mariette Corporation, Orlando Division, Orlando, Florida.
Propulsion: Thiokol Chemical Corporation.
Communications: Collins Radio Company.
Inertial Navigation: Bendix Corporation, Eclipse-Pioneer Division.

2767.111
PERSHING II BATTLEFIELD SUPPORT MISSILE

DESCRIPTION:

Pershing II is the name assigned to a US defence project, outlined in the FY 1975 budget proposals, for improving the accuracy of the Pershing missile (**2765.111**) and thus permitting the use of a lower-yield nuclear warhead to perform the same military function.

Most Pershing missiles currently deployed are believed to carry 400-kiloton warheads, and these have been criticised for being excessively large and destructive for battlefield use. What is now proposed is the addition of what has been described as a Radar Area Correlation Guidance system, a form of terminal guidance system which is expected to produce the desired improvement in accuracy and thus make the use of a smaller warhead operationally sensible – with consequent improvement in the political acceptability of the weapon.

Details of the correlation system are not known but it clearly involves a process of matching a radar picture obtained by missile-borne equipment with a similar picture obtained previously by reconnaissance. This principle has been known for some time and a rather similar notion is embodied in the TERCOM system for re-entry vehicles (see **2719.111**).

STATUS:

It is understood that earlier experimental work has now bought the project to an advanced development stage. $11 million was requested, in the FY 1975 budget, for further development work.

2804.111
SERGEANT BATTLEFIELD SUPPORT MISSILE

DESCRIPTION:

Sergeant is a field artillery ballistic missile, capable of carrying either a nuclear or a high-explosive warhead, and intended to provide missile support to a corps or field army. A second-generation system, it replaced the Corporal missile, and among the improvements offered were inertial guidance and solid-propellant propulsion. These features reduced the amount of ground handling equipment required by the system and resulted in a shorter reaction time than that of the command-guided liquid-fuelled Corporal.

Recent improvements in the electronics and procedures for automatic count-down have resulted in a still further reduction in reaction time. Units already in the field have been modified to incorporate these improvements.

The missile is composed of four major sections. These are the warhead, guidance, rocket motor and control surfaces. These sections are assembled just before firing and are transported to the firing position in special sealed containers. Similar missile sections are interchangeable. The guidance system is immune to known countermeasures.

Major items of a firing battery are the Launching Station, Organizational Maintenance Test Station, and the Missile Transport Trailer. In addition, the XM68E2 Sergeant Trainer, which simulates all technical characteristics of the missile, is used as a training device.

A Sergeant missile battalion comprises a headquarters, a headquarters battery, and two firing batteries with one launcher per firing battery. The battalion is usually assigned to a field army and

MGM-29A Sergeant missile erected for launching attached to a corps. Normally, three battalions will be found in each field army.

The Sergeant may be employed against large troop concentrations, enemy nuclear delivery systems, communications centres, and command and supply installations. Its mobility and air-transportability allow for rapid occupation and displacement from position.

CHARACTERISTICS:

Military Designation: MGM-29A

Type: Surface-to-surface tactical guided missile

Guidance: Inertial

Propulsion: Single stage solid-propellant rocket motor

Warhead: Nuclear or high-explosive

Missile Length: 10.5 metres

Missile Diameter: 79 cm

Launch Weight: 4,536 kg

Speed: Supersonic

Range: 45 to 140 km

DEVELOPMENT HISTORY:

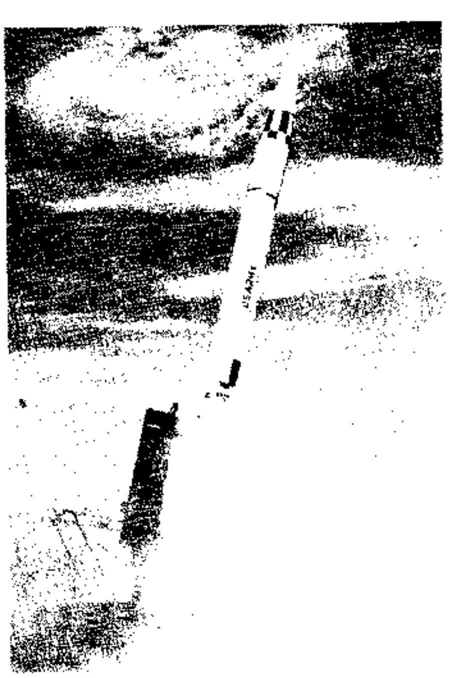
In 1955, Jet Propulsion Laboratories (JPL), the developing contractor for Corporal, predecessor of Sergeant, was awarded a contract for the Sergeant System. Sperry Utah Company entered the programme in 1956 as the co-contractor for research and development and the prime contractor for equipment production. The Sperry Utah Company, now the Univac Salt Lake City Company, took over complete prime contractor responsibility for the system in July 1960.

The Sergeant system is in operation with US troops in the United States and overseas. West Germany also has Sergeant. It is expected that Lance (**2682.111**) will replace Sergeant during the 1970s – and probably by 1975 in the USA.

MANUFACTURERS:

Prime Contractor: Univac Salt Lake City Company, Salt Lake City, Utah.

Rocket Motor: Thiokol Chemical Corporation, Bristol, Pennsylvania.



Launch of a Sergeant at White Sands Missile Range, New Mexico

2837.111
ROCKET-ASSISTED GUIDED PROJECTILES

DESCRIPTION:

Rocket-assisted projectiles have been in use for US field artillery for several years (see **2834.103**) but all such missiles in service are unguided.

Development of a terminal homing guidance system for such projectiles was initiated by the US Navy, but was subsequently handed over to the US Army. Laser guidance is known to be among the techniques being explored. No details are available but it seems reasonable to suppose that an accurate long-range fire capability, although desirable in itself, is not the sole reason for the development and that nuclear warheads have at least been considered.

MANUFACTURERS:

It is known that Martin Marietta and Texas Instruments have been competitively involved in one guided projectile project.

THE UNION OF SOVIET SOCIALIST REPUBLICS

2925.111
FROG 7 GUIDED BATTLEFIELD SUPPORT MISSILE

DESCRIPTION:

FROG (Free Range Over Ground) is a NATO name applied to what has grown to be a substantial family of heavy battlefield support weapons which can carry either nuclear or high-explosive warheads.

The majority (and possibly all) of these weapons are unguided and are described in Section 3 (**2920-24.103** and **2926.103**). A recent report, however, has suggested that the most recently introduced member of the family, Frog 7, may also exist in a guided version (the unguided version is described in **2926.103**). This report is based on evidence which came to light during the 1973 Arab-Israeli war when some, possibly guided, Frog 7 missiles with high-explosive warheads were fired against the Israeli forces by the Syrian Army.

If such a version of Frog 7 does exist it may confidently be expected to be radio command-guided, but no other information is available.

STATUS:

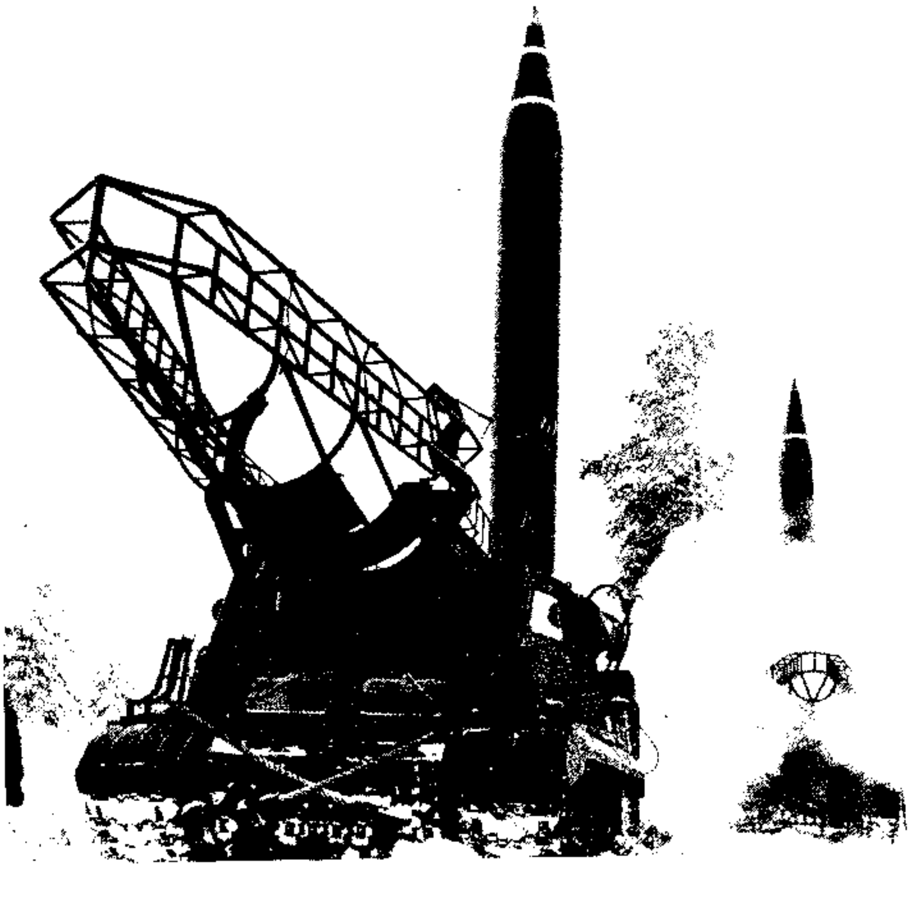
Not definitely known to exist but by no means an impossibility.

2969.111
SS-1B (SCUD A) BATTLEFIELD SUPPORT MISSILE

DESCRIPTION:

The family of heavy artillery rockets known by the NATO code name of Scud has two or, according to some sources, three members. The first, Scud A, which is generally identified with the US code SS-1B, is carried on and fired from a tracked vehicle, with a JS-III chassis similar to that used for Frog 1, has a liquid-propellant motor, is about 11 metres long and has a range of about 150 km. The tubular metal cradle in which it is supported elevates with it into the firing position; ladders in each side of the cradle give access to the warhead section when the missile is erected. According to Soviet reports the preparation time of this missile in service with army corps is more than one hour.

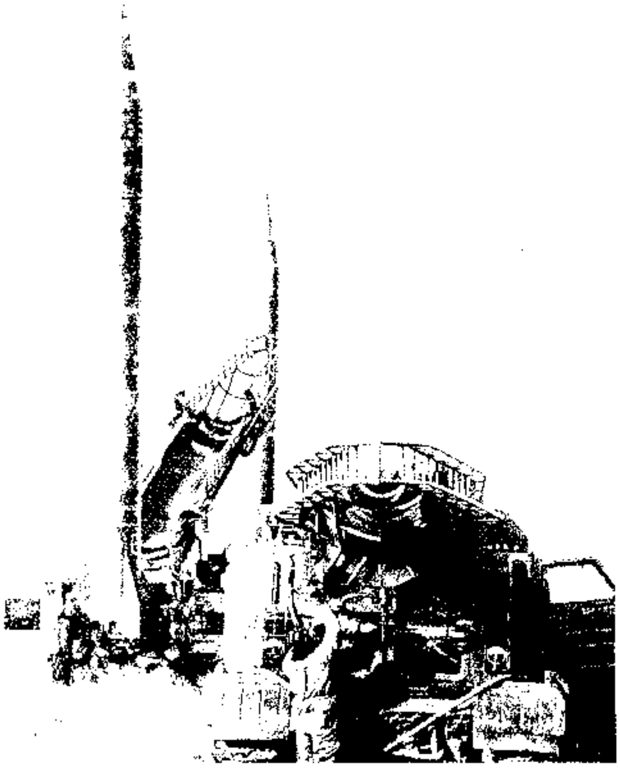
Unlike the Frog series of unguided missiles the Scuds have movable fins. The method of guidance used for the later Scuds is believed to be a simplified inertial system but appears previously to have been some form of radio command guidance. According to most sources Scud A is still a command-guided weapon.



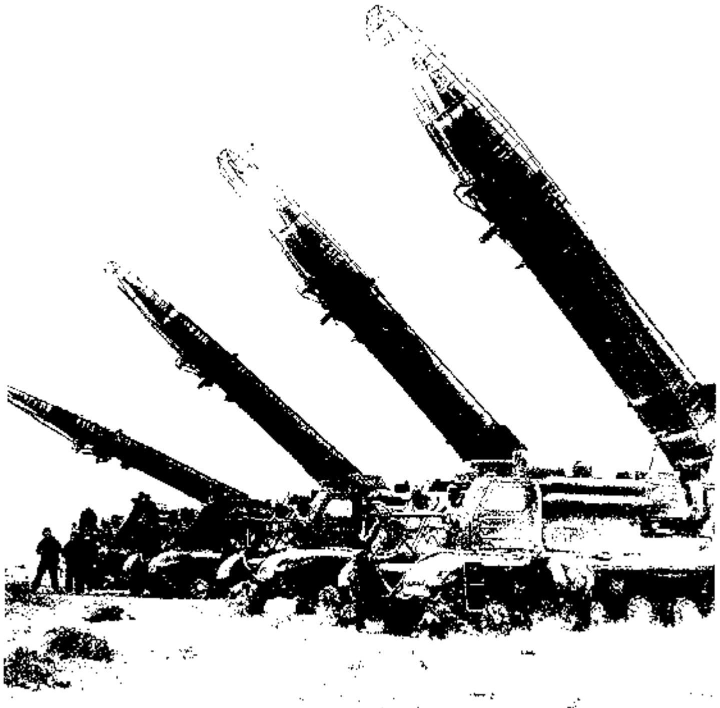
Scud-A missiles on exercises in January 1970 (Tass)

CHARACTERISTICS
Type: Surface-to-surface guided tactical missile
Guidance Principle: Radio command guidance
Guidance Method: By movable tail fins
Propulsion: Liquid propellant sustainer
Warhead: Believed optional nuclear or high explosive
Missile Length: About 10.5 metres
Missile Diameter: About 85 cm
Launch Weight: About 4,500 kg
Range: 80-150 km

STATUS:
Operational in Warsaw Pact forces



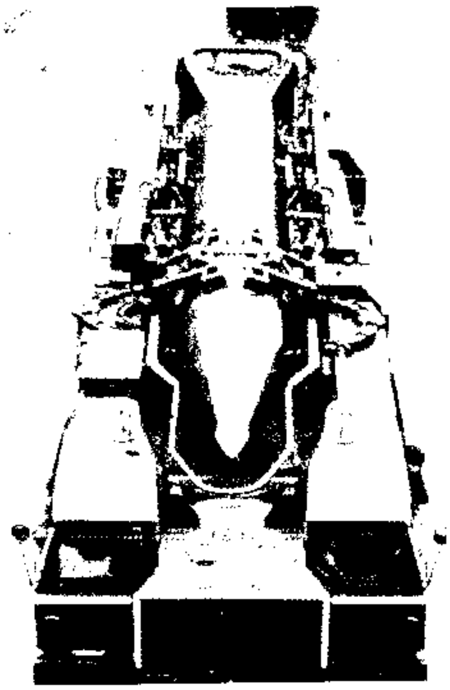
Scud-B missiles being erected (Novosti)

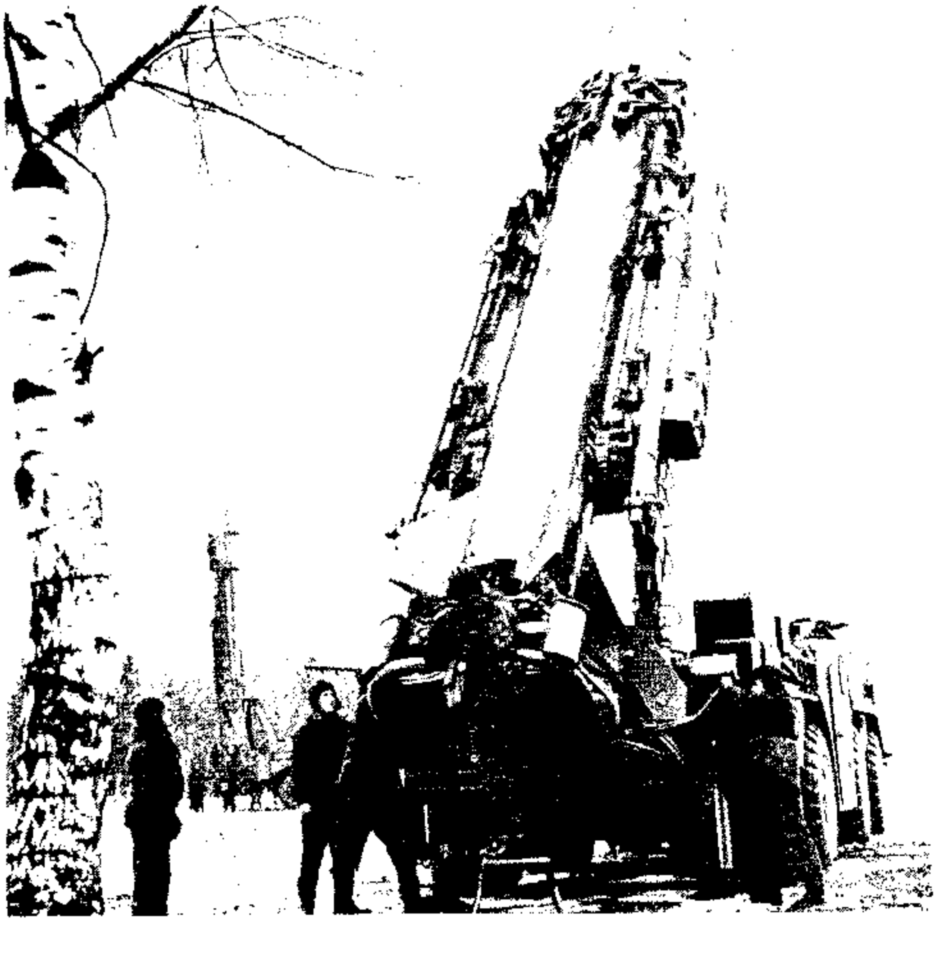


Two views of Soviet troops undergoing training with Scud-B surface-to-surface guided missiles (Tass)

2970.111
SS-1C (SCUD B) BATTLEFIELD SUPPORT MISSILE

DESCRIPTION:
Scud B, which is generally identified with the US code SS-1C, is somewhat larger than Scud A (about 0.5 metre longer) and is credited with a longer range. It first made its appearance mounted on a JS-III chassis similar to that used to transport Scud A but with the cradle mounting arrangements modified to accommodate and give front support to the longer missile. It is generally agreed that this missile is inertially guided.



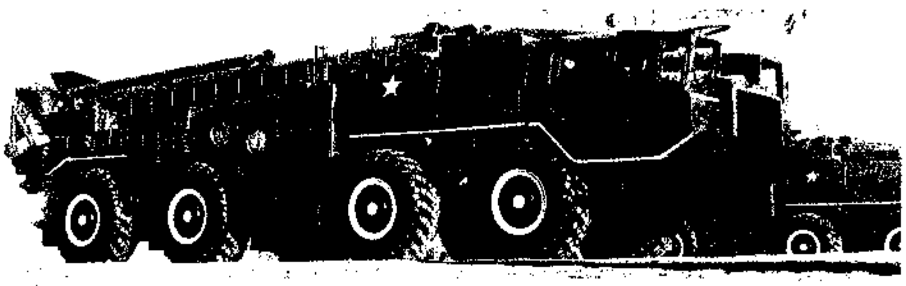


Scud B MAZ-543 mounting viewed from above

In 1965, however, the missile was seen mounted in a MAZ-543 wheeled transporter/erector/launch vehicle. The driver occupies the left-hand cab at the front and the launch operator with his console occupy the right-hand cab at the front. Behind them are seats for other members of the crew. A pair of sideways-hinged doors, between the two inner wheels on the left-hand side of the vehicle, give access to the control equipment.

CHARACTERISTICS:

Type: Surface-to-surface guided tactical
Guided Principle: Simplified inertial
Guidance Method: By movable tail fins
Propulsion: Liquid propellant sustainer
Warhead: Believed optional nuclear or high explosive
Missile Length: About 11 metres
Missile Diameter: About 85 cm
Launch Weight: Said to be about 6,300 kg



Scud-B surface-to-surface weapon system (Tass)

Range: 165-280 km – possibly a little more

STATUS:

Operational in Warsaw Pact forces. Also two brigades of "Scud missiles" were reported to have been deployed on the West bank of the Suez Canal at the time of the 1973 Arab-Israeli war. It was also reported that they were equipped with nuclear warheads. It is not definitely established that they were Scud B missiles but it seems probable.

2971.111

SS-1D (SCUD C) BATTLEFIELD SUPPORT MISSILE

DESCRIPTION:

There have been several references in the literature to a third member of the Scud family identified as Scud C or SS-1D. It now appears, however, that these references are in all probability erroneous, and that the idea that this third missile exists arises either from confusion with the longer-range Scaleboard missile (**2959.111**), which is also transported on a MAZ-543 vehicle, or from the change of transport vehicle for Scud B.

2959.111

SS-12 (SCALEBOARD) BATTLEFIELD SUPPORT MISSILE

DESCRIPTION:

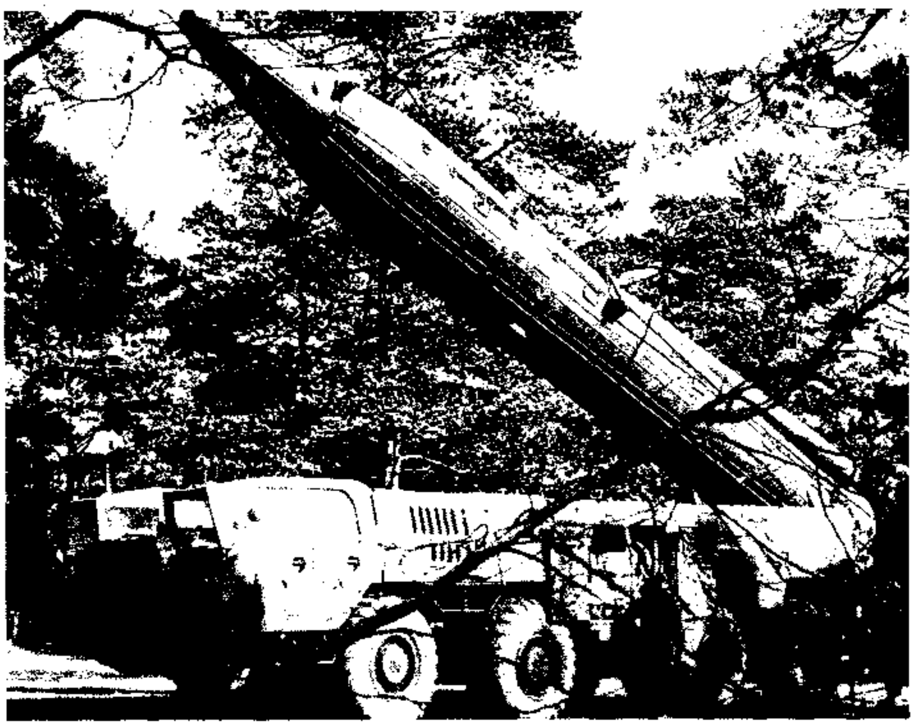
Scaleboard is the NATO name for a short medium-range ballistic missile which is identified by some sources with the SS-12 in the US series. It is a mobile missile and is normally transported on a MAZ-543 eight-wheeled vehicle similar to that sometimes used for Scud-B (**2970.111**). Its warhead has been reported to be in the megaton range. This suggests that it has rather greater destructive power than its approximate equivalent in NATO, the American Pershing missile (**2965.111**).

Unlike the Scud missiles, which in transit are exposed to view as they rest in their elevating cradles, the Scaleboard missile is enclosed in a ribbed split metal casing which is elevated with the missile into the firing position.

Scaleboard appears to be approximately the same length as Scud-B – rather more than 11 metres – but larger in diameter. Its range has been estimated in the region of 7-800 km. Nothing is known about its guidance system but it is presumed to be some form of inertial guidance suitable for use with a missile that is elevated from the horizontal to the vertical shortly before firing.

STATUS:

Believed to be fully operational in the USSR.



Scaleboard missile being erected. The access doors to the control equipment are open

COASTAL DEFENCE WEAPONS

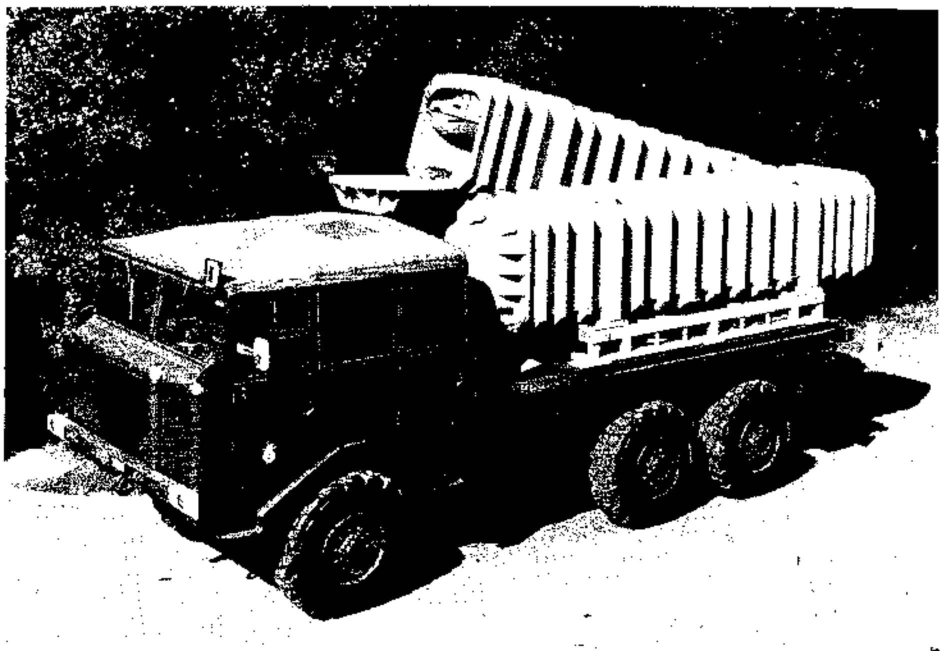
EXOCET COASTAL DEFENCE WEAPON
Description

This entry relates to a proposal by Aérospatiale, principal manufacturers of the MM38 Exocet ship-to-ship missile system (**1156.221**), to use the missile in a coastal defence role.

The proposal has not as yet been spelt out in detail so there is no information on the radar and other ancillary apparatus that might be used. General information on the weapon system can be found in the Shipborne Weapons sub-section below. The reader's attention is particularly drawn to the note on Improved Exocet in entry number **1156.221** because one of these versions of the missile could well form the basis of a coastal defence system.



Exocet launched from fixed container

INTERNATIONAL

1337.121
OTOMAT ANTI-SHIP MISSILE (FRANCE/ITALY)
Description:

The Otomat is an anti-shipping missile initially developed for launching from naval vessels but also designed in fixed and mobile land launched and air-launched versions. Range for the land-based version, either fixed or in a vehicle, is up to 200 km and speed is in the region of Mach 1. Inertial guidance plus a radio altimeter is employed for the cruise phase of the missile's trajectory with a Thomson-CSF active homing head for the terminal phase. A more detailed description is given in Entry No. **1336.221**

Manufacturers:

Engins Matra, 78-Velizy, France.
Oto Melara, La Spezia, Italy.

SWEDEN

2372.121
RB 08 COASTAL DEFENCE WEAPON
Description:

The Swedish RB 08 surface-to-surface cruise missile is intended for use either as a shipborne weapon or for coastal defence.

Detailed information on this system will be found in the Shipborne Weapons sub-section below (**2366.221**).

RB 08A boosted off its launcher

THE UNION OF SOVIET SOCIALIST REPUBLICS

2953.121
SALISH CRUISE MISSILE
Description:

This is the NATO code-name given to a cruise missile which is similar to and probably derived from the air-launched missile whose NATO code-name is Kennel (**1148.311**) as also is the missile known as Samlet (**2951.111** below).

Powered by a turbojet motor this missile has a range that has been estimated as anything from 100 to 200 km. Since Samlet appears to be the more modern of the two missiles it may be wise to assume not more than 100 km for Salish.

When shown publicly, Salish has appeared mounted on a short ramp on a low trailer. Mounted for launching, however, it has been seen on a larger ramp and with a JATO bottle attached.

Like Samlet, Salish has a radome above the air intake in the nose. This is believed to cover a semi-active homing equipment. There are no other obvious indications of guidance equipment.

Approximate dimensions are given below in the entry for Samlet.

2951.111
SAMLET CRUISE MISSILE
Description.

Like Salish, the missile known to NATO as Samlet is a surface-to-surface version of the air-to surface jet powered cruise missile whose NATO code name is Kennel. It has been operational in the USSR, Poland and Cuba as a coastal defence weapon. When shown publicly Samlet has been mounted on what appears to be its launching ramp constructed as a trailer. For launching a JATO bottle is presumably necessary.

Samlet, like Salish, has a radome over its jet air intake. The radome is larger than that on Salish and Samlet also has what seems to be an electronics pod mounted on its tail fin. The radome is assumed to cover a semi-active radar homing seeker: the other device may contain the receiver and associated apparatus of a command guidance link. Apart from these differences the two missiles appear very much alike and the following approximate data are probably equally true of both.

CHARACTERISTICS:

Length: Approx 7.0 m

Wing Span: Approx 5.0 m

Weight: Believed about 3 tons

Cruising Speed: Mach 0.8-0.9

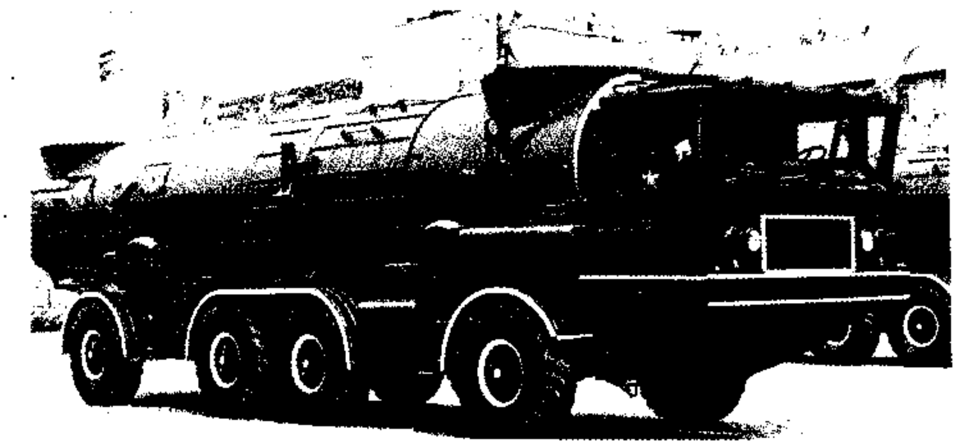
Range (Samlet): Possibly as much as 200 km with mid-course guidance

2975.121
SHADDOCK MOBILE CRUISE MISSILE

DESCRIPTION:

Too little has been seen of this missile on public display for it to be described with confidence. The general view seems to be that it is a ramjet or turbojet-powered cruise missile with hinged wings that open out when the missile leaves its cylindrical launcher. Initial boost is provided by two rocket units under the rear of the fuselage. Length of the missile is estimated at about 10 metres and the diameter of the fuselage is probably around 1.0 metre.

Shaddock – or a missile very like it – is best known as a naval weapon and is described as such below (**2976.221**). It appears, however, that it is used by the land forces of the USSR; and this view is reinforced by the appearance of the container/-transporter illustrated here which is clearly capable of elevating the missile to an inclined launch position.



Shaddock surface-to-surface cruise missile in its mobile container launcher (Novosti)

While no doubt it could be used as a ground-to-ground weapon, however, it seems rather more likely that it would be used as a coastal defence weapon – if only because of its ability to cruise at speed at low altitude over water.

Guidance is by radio-command with infra-red homing. Range capability is in the order of 450 km, but mid-course guidance by aircraft or helicopter would be necessary for such a long mission.

SHIPBORNE WEAPONS

INTRODUCTION.

This section deals with shipborne surface-to-surface weapons for anti-ship and shore bombardment purposes. In certain cases it will be found that the missile employed in such systems has other roles, and the practice in these instances is to cross refer to the appropriate entries for other applications of a given missile. In general it will be found that the most comprehensive description of the missile as a 'round' will appear under the entry for its principal function, but adequate data for an appreciation of a missile's performance is given in the entry for each system in which it is employed.

Naval guns and unguided bombardment rockets are contained in Section Three of this volume, and naval fire control systems are described in this section of the book (One).

CANADA

2035.221
CANADIAN SEA SPARROW MISSILE SYSTEM

DESCRIPTION:

This system is described more fully in a later section of this book dealing with shipborne surface-to-air weapon systems, which is the principal function of the Canadian Sea Sparrow System, also known as CCRMS (Canadian Close Range Missile System), under Entry **2036.231**. The version of Sparrow III missile used is the AIM-7E2, as applied to shipborne use and which then carries the designation RIM-7H. This missile is also employed in the NATO Sea Sparrow system (**2770.231**) but in that system the missile is provided with folding wings which allow the use of smaller containers. Both air and surface targets can be engaged by the Canadian Sea Sparrow system.

STATUS:

Early sea tests of the Canadian Sea Sparrow were conducted in the summer of 1973 and full firing tests have been scheduled for 1974. Four DDH280 Class destroyers are fitted.

MANUFACTURERS:

System – Raytheon Canada Ltd, Waterloo, Ontario, Canada.

Fire Control System – N.V. Hollandse Signaalapparaten, Hengelo (O.), Netherlands.

FRANCE

1156.221
MM 38 EXOCET SURFACE-TO-SURFACE MISSILE

DESCRIPTION:

Exocet is a surface-to-surface tactical missile designed to provide surface warships with all-weather attack capability against other surface vessels. It can be fitted in major and minor warships including fast patrol boats and hydrofoils.

The missile is in the form of a streamlined body equipped with four cruciform wings and four tail control surfaces in the same planes as the wings.

Propulsion is provided by a two stage, solid propellant motor.

Exocet's range is about twenty nautical miles (38 km), flying at very low altitude. Its cruising speed is high subsonic and it carries a high explosive warhead.

Missiles are stored in box-type containers which also serve to launch them. These launcher-containers may be installed in fixed positions or on rotatable mountings.

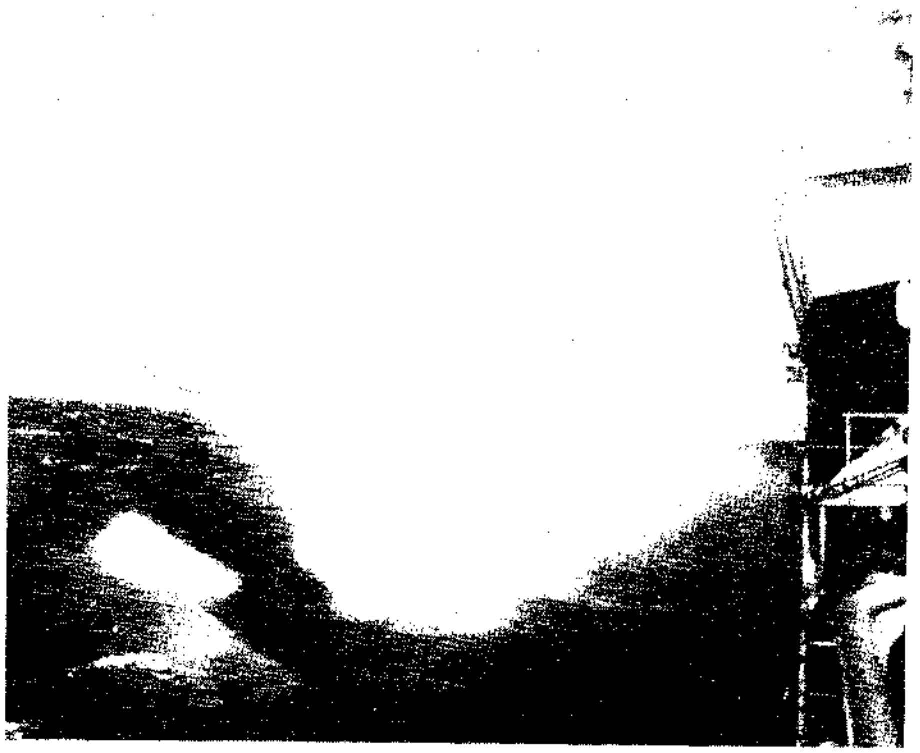
The missile flight consists of a preguidance phase during which it flies towards the target, whose range and bearing have been determined by the fire control computer and set up in the missile preguidance circuits before firing, and a final guidance phase during which the missile flies directly towards the target under the control of its active homing head. Throughout the whole flight the missile is maintained at very low altitude by a radio-altimeter.

Exocet is understood to use several elements similar to those fitted on the German Kormoran air-to-sea missile (**1180.321**) developed jointly by Messerschmitt-Bölkow-Blohm and Aerospatiale for instance the twin-gyro inertial guidance system for the initial trajectory. The long burn cruise motor is an extended range version of the motors used on the Kormoran and the TV version of Martel. The radio altimeter is produced by TRT under the designation RAM 01. The warhead is reported to weigh between 150 and 200 kg.

The terminal guidance phase (approximately the last 10 km) is by means of the ADAC radar homing head developed by Electronique Marcel Dassault.

To launch Exocet, the ship's fire control system is normally connected to the ITS (Installation de Tir Standard, or Exocet ship system). The ITS is assembled by the Ruelle Establishment (DTCN) under SNIAS as prime contractor, with several British sub contractors. ITS is fitted on the French, British and W. German ships armed with Exocet. The Thomson-CSF Vega fire control system (**1053.281**) can be used with or without ITS.

The TRT RAM.01 radio altimeter carried by the Exocet missile is reported to be capable of permitting safe flight at a height of between 2 and 3 m above the wave crests of the sea at a speed of Mach 1.



Exocet launch

DEVELOPMENT

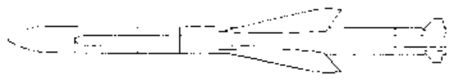
Development has been carried out by Aérospatiale in collaboration with the French Government military research establishments, to meet a French Navy requirement.

STATUS:

Exocet has been adopted as the standard surface-to-surface missile of the French Navy. Official announcements have been made regarding orders from West Germany, Greece and the United Kingdom and other negotiations are in progress with countries interested in purchasing the system for either shipborne or shore-based applications. Early in 1972 it was the manufacturer's view that there was a market for a minimum of 1,500 missiles and by the end of that year some 600 had been ordered. Production at that time was under 10 units per month but a rate of about 25 per month was thought possible without retooling.

Manufacturer's tests were concluded in July 1972 with a direct hit, by a missile fitted with a live warhead, on a 350-ton hulk which was sunk.

Evaluation trials by the French Navy, with the participation of the Royal Navy and the West German Navy, began in October 1972.



MM38 Exocet

The first French naval vessel to be equipped with the missile is the ASW frigate *Tourville*. Six Exocet launchers are mounted.

The missile is already operational on four FPBs of the Greek Navy, each of which is equipped with four missiles. Deliveries to the Royal Navy began in March 1974. Other countries known to have ordered Exocet are Brazil, Chile, Malaysia and Peru.

Improved Exocet

An improved version of Exocet, using an improved solid propellant motor, is in development. It is understood that final decisions on possible configurations have not yet been taken but because the new motor offers the possibility of producing either a smaller and lighter missile with the MM 38 performance or a missile of the size of the MM 38 with superior performance it may be that more than one "Mark 2" version will be tried. Smaller versions could find applications on hydrofoils and other light vessels or on submarines (**2219.421**) whereas the more powerful versions would be useful in coastal and possibly some airborne applications.

In the latter part of 1973 two air-launched versions of Exocet were revealed under the designations AM-38 and AM-39, for helicopter and fixed-wing deployment, respectively. These are described in the section on air-to-surface tactical weapon systems which appears later in this book.

INTERNATIONAL

1336.221
OTOMAT ANTI-SHIP MISSILE (FRANCE / ITALY)

DESCRIPTION:

Otomat is an anti-ship missile intended initially for launching from naval platforms of any size from fast patrol boat upwards, but also capable of land deployment (fixed or mobile), and use from aircraft. The main physical characteristics of the missile are: length 440 cm, diameter 40 cm (front) and 46 cm (rear), wing span 1.19 cm, and weight about 700 kg (shipborne version). Weight for the aircraft-launched version is much reduced by elimination of the boosters which are not required in this mode of operation. The helicopter and land versions weigh the same as the shipborne model. A semi armour-piercing warhead of over 200 kg is carried. The speed has not been revealed but may be assumed to be close to Mach 1.

Otomat missiles are delivered in containers which also serve as launchers, the containers being mounted on prepared locations. Propulsion during cruise is by a Turboméca turbojet engine, the four air inlets for which are in the wing roots. Two lateral jettisonable boosters are attached for the launch phase. Range is over 80 km, but fuel capacity is stated to be sufficient for ranges beyond the conventional radar horizon of a ship.

A Mark II version of Otomot has been developed, the principal features of which are increased range (about 100 km) and the use of a new homing head produced by the Italian SMA concern (Segnalamento Marittimo e Aero). The latter allows Otomat to follow a sea-skimming flight path up to the point of impact with the target. The Otomat Mk I, which is fitted with a Thomson-CSF 'Col vert' homing head performs a late 'pull-up' and dive trajectory to the target. A third version, which has a reported range of 200 km, is in development for the Italian forces under the designation Téséo. This is probably for coastal defence applications.

OPERATION:

Subsequent to launching the Otomat follows a cruise phase towards the target's predicted position, flying at low level under radio altimeter control and inertial guidance. An active homing head is used for the terminal phase.

The Otomat is claimed to be compatible with any normal target designation radar and fire control system.

DEVELOPMENT:

Development of the Otomat began in 1969 under a fixed-price contract and was jointly undertaken by Engins Matra in France and Oto Melara in Italy. The programme was first revealed in late 1970. Prior to the combined effort, each of the two concerns had been working individually in this area of missile technology.

Frame from cine-record of Otomat test firing

STATUS:

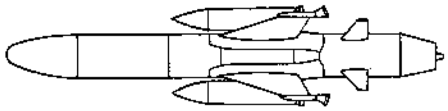
First test firings took place in early 1971, booster acceleration tests taking place in Sardinia in April of that year. Guided test firings started in December 1971 and the first complete test of the system took place in February 1972 and was completely successful, the missile impacting on its target several tens of kilometres away.

The first launch of Otomat Mk II took place in January 1974.

An extended range version, known as Téséo, is in development for coastal defence purposes.

STATUS:

In February 1974 it was announced that orders had been received for 120 Otomats. Most of these are for the Italian Navy which will equip six hydrofoil patrol craft and some coastal batteries. Forty are stated to have been ordered by Venezuela to arm four patrol boats, and these are due for delivery in 1974. A third, unnamed country is reported to have ordered Otomat.



Otomat Mk I

MANUFACTURERS:
Engins Matra, 78-Velizy, France.
Oto Melara, La Spezia, Italy.

ISRAEL

6019.221
GABRIEL SHIPBORNE SURFACE-TO-SURFACE MISSILE

DESCRIPTION:

Gabriel is a shipborne anti-ship missile developed in Israel and designed for installation in ships from about 250 tons upwards.

A sea-skimmer, the missile is transported in, stored in, and launched from hermetically sealed, reinforced fibreglass containers which also hold the missile launching rail and the hydraulically-operated container door. The missile is pre-adjusted and tested and requires no further tests or adjustments after installation. The standard

Gabriel firing from Israel fast patrol boat. One of the launch cells can be seen launcher carries three missile cells on a rotatable pedestal, but single, possibly fixed, cells also exist. The missile, whose general configuration can be seen from the accompanying photograph, is powered by a solid-propellant rocket motor.

A sophisticated guidance and homing electronics system is carried by the missile, all parts of which appear to have been developed in Israel. While details of this system have not been made public it appears that over the major part of its trajectory the missile is radar-guided in the horizontal plane and maintains its height above surface by means of radio altimeter. A manual/optical alternative control system is available for use in conditions where radar guidance is not practical. When it nears the target the missile's homing system takes over: this has been described as a semi-active radar homing system, but it seems probable that an alternative form of homing is also available for use in ECM conditions.

Gabriel's cruising speed is in the high subsonic region. It was announced during 1972 that there were two versions of Gabriel in production, one having nearly twice the range of the other. It is believed, however, that the only differences between the two are that one has a larger propulsion unit and may incorporate additional guidance equipment for over-the-horizon operation.

According to one American source, the latter capability is achieved by adding a television camera to the Gabriel missile and providing the necessary video and command links.

CHARACTERISTICS:

Type: Shipborne surface-to-surface guided weapon system

Guidance: Radar control from ship plus missile-borne homing system

Propulsion: Solid-propellant two-stage rocket motor. First stage 3,600 kg for 3 seconds. Second stage 77 kg for 100 seconds (short-range version) or 200 seconds

Warhead: High-explosive 180 kg

Length: 3.35 m

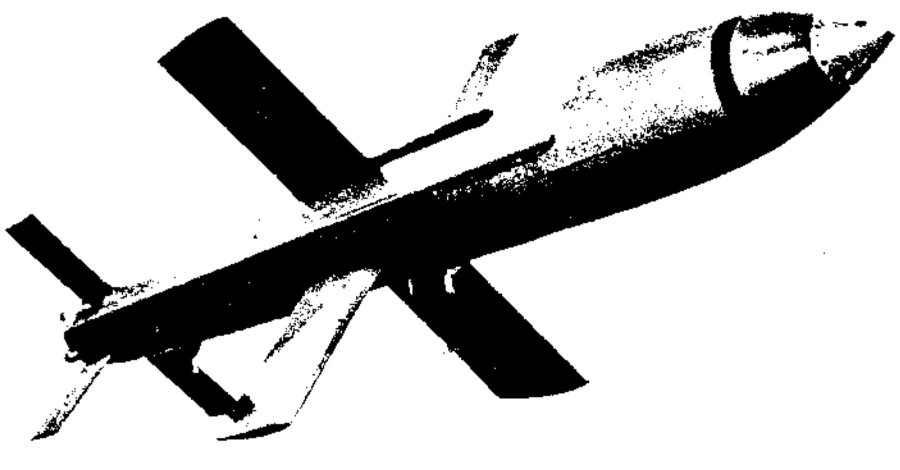
Diameter: 32.5 cm

Wing Span: 60 cm and 138 cm

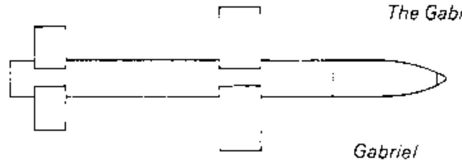
Launch Weight: 400 kg

Range: 2 – 22 km (1 – 14 nm) or 2 – 41 km (1 – 26 nm)

Speed: Mach 0.7



The Gabriel missile



Gabriel

STATUS:

Developed in Israel during the nineteen-sixties, the missile is now operational in fast patrol boats of the Israeli Navy. In addition, up to the end of May 1972, export orders to a value in excess of £15 million had been received for the missile. Names of customers have not been disclosed but at least one is believed to be South American and Singapore has been quoted as another user.

Missile prices have been reported to be in the region of £35-40,000 or about £1 million for a six-launcher installation with radar, directors, etc. This gives some indication of the scale of Gabriel sales overseas.

The launch of the first of a new series of Israeli-built 415-ton patrol boats was announced in February 1973. It is understood that these vessels will be equipped with the long-range Gabriel missile.

MANUFACTURER:

Israeli Aircraft Industries Ltd, Lod Airport, Israel.

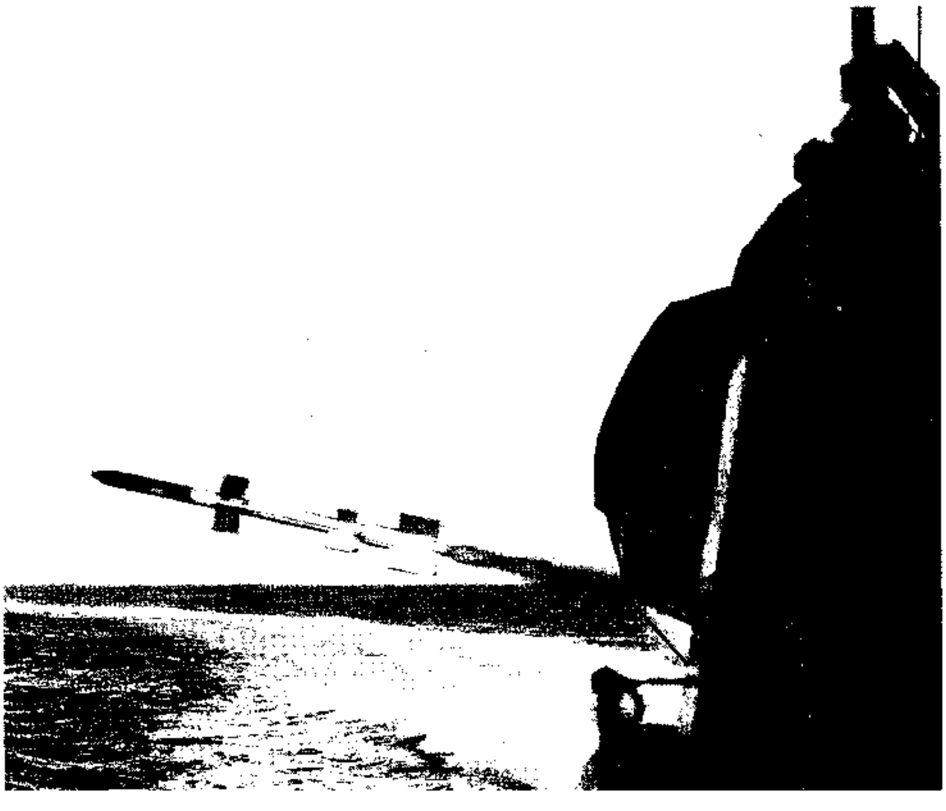
SEA KILLER MISSILE SYSTEMS

The Italian shipborne surface-to-surface missile systems Nettuno (**2240.221**) and Vulcano (**2253.221**) have long been known outside Italy as Sea Killer Mk 1 and Sea Killer Mk 2 respectively. Both systems were originally developed by Contraves Italiana SpA and were taken over by Sistel SpA when that company was formed in 1969.

Sistel (Sistemi Elettronici) SpA was formed jointly by Montecatini Edison, Contraves Italiana, Fiat, Finmeccanica and Snia Viscosa, to develop new products in the missile field, benefiting from the experience of Contraves in this area. This venture has been supported by the Italian Ministry of Defence.

The alternative names mentioned above have now been abandoned officially in favour of the Sea Killer nomenclature, which has been retained for the latest weapon of this family, Sea Killer Mk 3 (**2242.221**).



Sea Killer Mk 2 launch

2240.221
SEA KILLER MK 1 (Nettuno)

DESCRIPTION

A short-range ship-based surface-to-surface guided missile, (formerly Nettuno but now officially the Sea Killer Mk 1) is now in service with the Italian Navy. Both the Mk 1 and Mk 2 Sea Killer missiles can be employed in the Marte (**1651.231**) helicopter anti-ship weapon system.

OPERATION:

Launched from a trainable five-round multiple launcher the missile normally operates as a beam-rider for bearing guidance – using the Sea Hunter (**7021.281**) or similar fire control radar – while altitude control is provided by means of a missile-borne radio altimeter which can be controlled from the launch point to adjust the height of the missile in flight. Alternatively, if beam-riding is rendered impossible by interference, provision is made for radio command control of the missile – optical tracking being by means of a television sub-system which, together with the command transmitter, is mounted on the Sea Hunter radar pedestal. An important characteristic of the guidance technique is the achievement of a very low flight altitude which makes it difficult for an enemy to detect and track the missile.

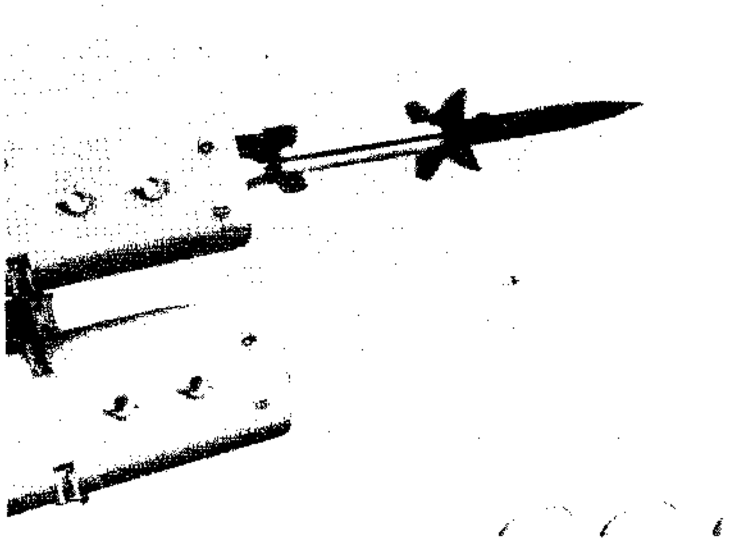
Sea Killer Mk 1 is intended to be integrated with the ADT A40 (Sea Hunter 2) or a similar fire control system although integration with other similar radars has been studied and offered to a number of potential users. The ADT A40 is basically a gun fire control system but it can be upgraded to a gun/missile control system by the addition of a small quantity of additional apparatus.

CHARACTERISTICS:

Type: Shipborne short-range surface-to-surface tactical guided missile

Guidance Principle: Beam-rider/radio command/radio altimeter plus optical/radio command guidance in interference conditions

Guidance Method: By control of movable cruciform surfaces at mid-point on body. Stabilisation by cruciform tail fins.



Sea Killer Mk 1 launch

Propulsion: Solid-propellant rocket motor, 2000 kg st for 5 seconds

Warhead: High explosive (35 kg) fragmentation type with impact/proximity fuse

Missile Length: 3.73 metres

Missile Diameter: Body (cylindrical): 0.206 metres. Span: 0.857 metres

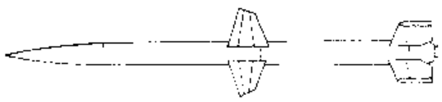
Launch Weight: 170 kg

Speed: Subsonic after burnout

Range: Over 10 km

DEVELOPMENT:

Development was initiated by Contraves Italiana SpA in 1963 and the first prototype was completed in 1966. The first service installation was made in 1969. In the same year responsibility for the project was taken over by Sistel SpA.



Sea Killer Mk 1

Subsequently, the Sea Killer Mk 1 has been applied to the helicopter-launch role in the Marte programme (**1651.321**) described in the air-to-surface tactical missiles section.

MANUFACTURER

Sistel SpA, Via Tiburtina 1210, 00131-Rome, Italy.

2253.221
SEA KILLER MK 2 (Vulcano)

DESCRIPTION

Similar in many respects to the earlier Sea Killer Mk 1, the Mk 2 Sea Killer (once bearing the Italian designation Vulcano) is a shipborne surface-to-surface tactical guided missile. It is, however, larger than Sea Killer Mk 1 and is powered by a two stage rocket motor. Both the Mk 1 and Mk 2 Sea Killer missiles can be employed in the Marte (**1651.231**) helicopter anti-ship weapon system.

OPERATION:

Like the Mk 1, Sea Killer Mk 2 can be launched from a trainable five-round multiple launcher and uses the same beam-riding plus radar altimeter guidance supplemented by radio command guidance when required. The missile can also be launched from deck-fixed launching containers if this is operationally more convenient. The missile's ability to cruise close to the surface of the sea is operationally important.

Sea Killer Mk 2 is also intended to be integrated with the ADT A40 (Sea Hunter 4) or a similar fire control system, the missile checkout, firing and guidance control being centralised in the missile control console. No launcher crew and no shipboard maintenance of missiles is required.

CHARACTERISTICS

Type: Shipborne medium-range surface-to-surface tactical guided missile

Guidance Principle: Beam-rider/radio command/radio altimeter plus optical/radio command guidance in interference conditions

Guidance Method: By control of movable cruciform surfaces at mid-point on body. Stabilisation by cruciform tail fins

Propulsion: Solid propellant booster and sustainer. SEP 4,000 kg st and SEP 100 kg st

Warhead: Semi-armour piercing high explosive (70 kg). Impact and proximity fuses

Missile Length: 4.7 metres

Missile Diameter: Body: 0.206 metres. Span: 0.999 metres

Sea Killer Mk 2 launch

Launch Weight: 270 kg

Speed: Transonic. Subsonic after burn out

Range: 25 km

DEVELOPMENT

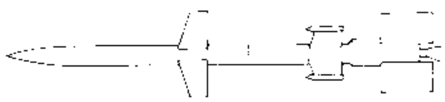
Development was initiated by Contraves Italiana SpA in 1965 and the first prototype was completed in 1969. In the same year the project was transferred to Sistel SpA. The system is operational on four Vosper Mk 5 frigates of the Imperial Iranian Navy and the missiles are in production.

Like the Sea Killer Mk 1, the Mk 2 version is used in the Marte helicopter-launched anti-ship missile system (**1651.321**).

MANUFACTURERS

The missile is manufactured by Sistel SpA, Via Tiburtina 1210, 00131 Rome, Italy.

Sea Killer Mk 2 missile



Sea Killer Mk 2

2242.221
SEA KILLER MK 3 SHIPBORNE SURFACE-TO-SURFACE MISSILE

DESCRIPTION:

This third missile in the Sea Killer series, now under development, incorporates features that have proved satisfactory in earlier members of the series but is a larger and more powerful weapon with a bigger warhead, a longer range and a more elaborate guidance system. Significant missile changes are the provision of a second sustainer motor and the addition of radar homing.

Basically, the system comprises a missile control console (MCC), launchers and missiles, but with these must be associated a stabilised platform, the ship's log, an anemometer and appropriate primary and secondary radars or other target information sources; the platform and log, of course, provide ship's motion data to the MCC.

Once a target has been identified as hostile its position data are inserted, in digital form, into the MCC where the launch computer determines, from these and the other input data, whether or not the target can be engaged. If it can, the computer generates a flight programme for the missile which, after a predetermined boost phase, will bring the missile to within radar homing range of the target.

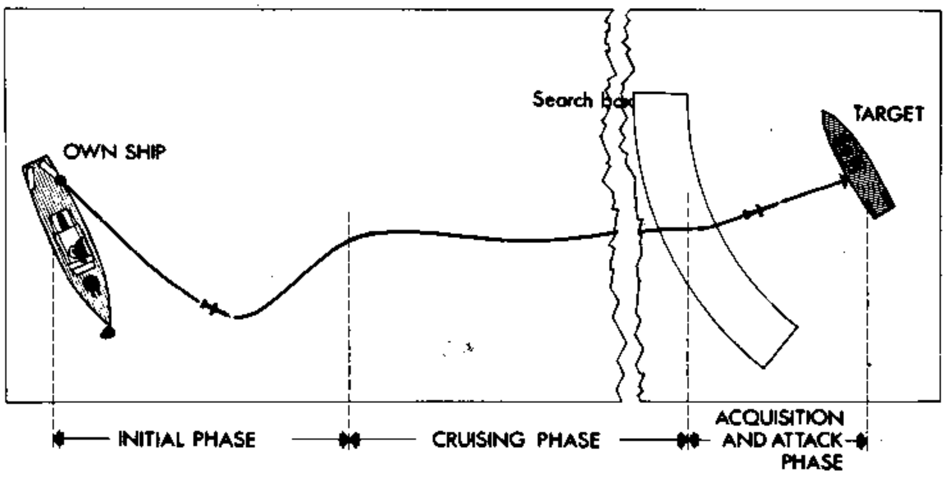
This programme is continuously updated until the firing command is given, whereupon the computer takes control of the automatic launching sequence.

The first phase of the missile's flight is a booster-powered climb during which the booster burns out and separates. At the peak of the climb the missile reaches an altitude of 120 metres. Following booster separation roll control is activated, the missile flight is stabilised and the missile is automatically guided according to the programme inserted by the MCC. Azimuthal guidance is by directional gyroscope and the required altitude is maintained by reference to a radio altimeter. During all the post-boost phases propulsion is provided by the sequential firing of the two sustainer motors.

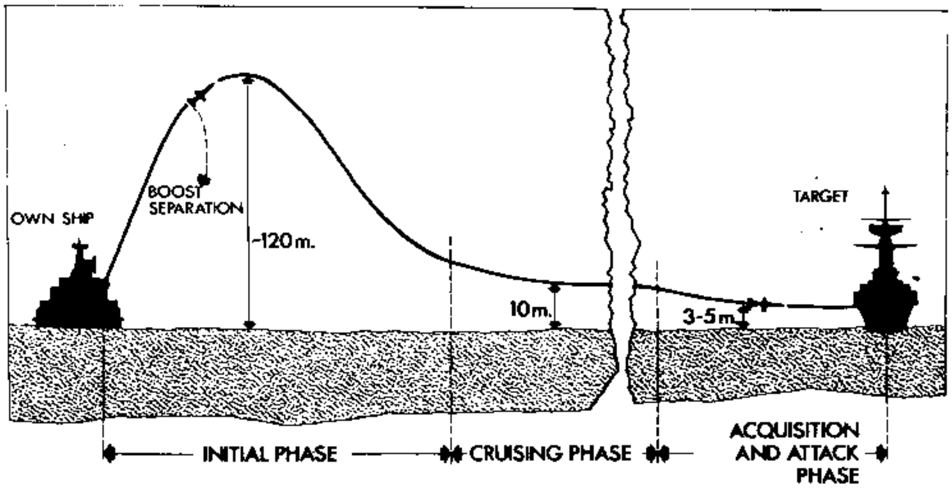
This second or cruise phase of the flight ends when the missile reaches a point within a "box" which is close enough to the target for the radar homing system to work with a high probability of success. Once automatic detection has taken place the homing radar tracks the target and steers the missile to its destination. During the search phase of this final process the homing radar uses a 4 km distance gate (although the maximum acquisition range of the radar on a typical ship target is considerably more than that). After lock-on the antenna search stops and range and azimuth tracking circuits are energised, using the target co-ordinates determined during the acquisition phase as imputs.

CHARACTERISTICS:

Type: Shipborne extended range surface-to-surface tactical guided missile



Flight phases in horizontal plane



Flight phases in vertical plane

Guidance Principle:
Cruising phase:
Horizontal: directional gyroscope system
Vertical: radar altimeter
Attack phase:
Horizontal: active radar homing
Vertical: radar altimeter

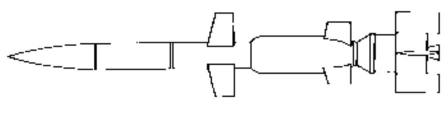
Guidance Method: By one set of cruciform wings at the centre of the missile

Propulsion: Solid propellant booster with approx 10,000 kg st for 1.6 sec plus two solid propellant sustainers each of approx 100 kg st for 70 secs

Warhead: HE, semi-armour-piercing. Weight 150 kg. Impact/proximity fuse

Missile Length: 5.3 metres

Wing Span: 1.09 metres



Sea Killer Mk 3

Cruising Speed (after booster burn-out): 280 m/sec

Launch Weight: 548 kg approx

Range: More than 45 km. Very low level

Sistel SpA, Via Tiburtina 1210, 00131-Rome, Italy.

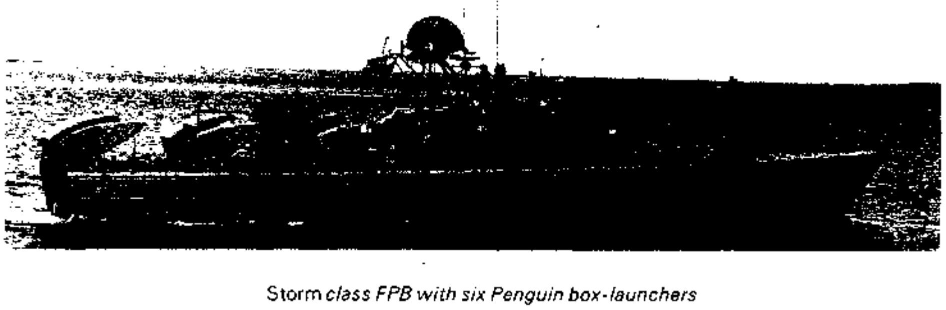
NORWAY

1339.221
PENGUIN ANTI-SHIP MISSILE

DESCRIPTION:

Penguin is a surface-launched anti-shipping missile primarily intended to provide small, fast naval craft with a powerful striking capability against larger vessels. It carries a 120 kg Bullpup ASM-N-7A warhead at Mach 0.7 over a range of at least 20 km. An impact fuse is fitted and the boost and sustainer motor is solid-propellant powered.

The missile is mounted on a simple launcher which is built into a container which serves as protection against weather and also serves as packing for transport to and from the ship. This unit, the box-launcher, is delivered as a complete and tested item from the base to the ship. Combined weight of box-launcher and missile is about 500 kg. Typical ship installations comprise four or six deck-mounted box-launchers. These are located on prepared mounts which incorporate an



Storm *class FPB with six Penguin box-launchers* umbilical cord connection. When fitted, the missiles are ready for immediate firing and no on-board service or repair is performed. Automatic testing can be effected from the missile control panel in the operations room.

OPERATION:

The Penguin missile employs inertial guidance for the cruise phase of its flight path, with passive infra-red homing to the target for the terminal phase. After launch the missile is thus independent of the parent vessel which is thereby freed to take evasive action or engage a further target.

Design requirements included missile range comparable to the maximum effective radar range for fast patrol boats and a passive mode of operation. Target detection, acquisition and designation is therefore by means of the launch vessel's radar and fire control system. Upon target acquisition, the fire control computer calculates the bearing so the predicted point of impact and the missile inertial guidance system is automatically slaved to the Kongsberg SM-3 computer data. The missile is then fired in the general direction of the target. After launch, the missile follows a programmed trajectory toward the predicted impact area. This programme can be varied.

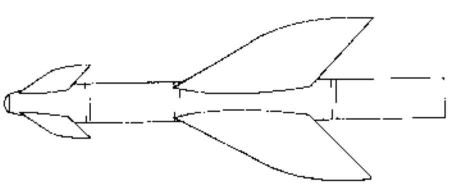
Prior to acquisition of the target by the missile's infra-red homing system this operates in a search mode, scanning a sector ahead of the flight path. Upon detection of the target, the homing system tracks the target and generates signals which are used to direct the missile to the target.

The Norwegian operational requirements relating to the Penguin system call for a warhead capable of inflicting serious damage on a destroyer. A vessel of this type, in normal circumstances would be capable of detecting an attacking fast patrol boat whilst still beyond the latter's radar range. Although not mentioned by the Norwegian authorities, the Penguin system would appear to have the potential to counter this by a completely passive mode of attack.

Passive direction finding equipment could provide bearing information on the radar transmissions of a potential target, and this information could be used to provide the Penguin missile guidance system with initial cruise data.

CHARACTERISTICS:

Type: Shipborne surface-to-surface tactical guided missile



Penguin

Guidance Principle: Inertial en-route guidance with infra-red terminal homing

Guidance Method: Aerodynamic by moving wings

Propulsion: Two-stage solid-propellant motor

Warhead: 120 kg semi-armour-piercing. Impact fuse

Length: 3.00 m

Diameter: 28 cm

Span: 1.40 m

Launch Weight: 330 kg

Weight with Box-Launcher: 500 kg

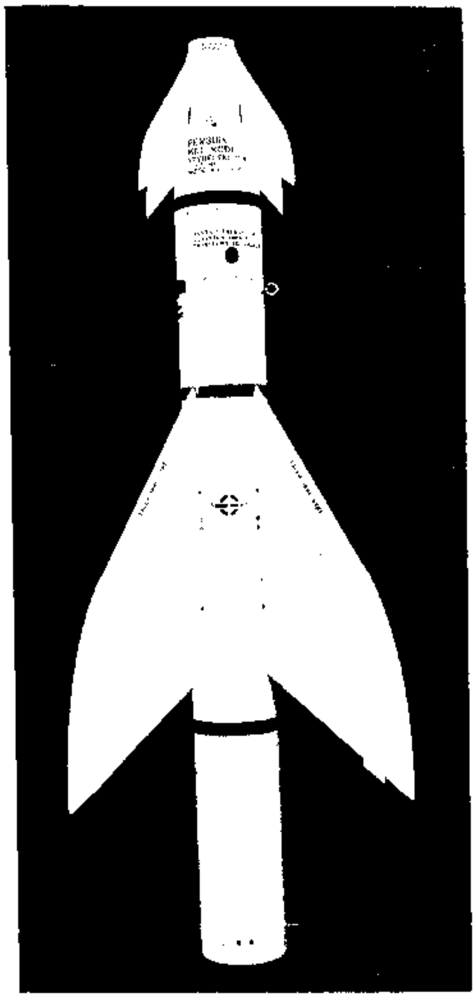
Cruising Speed: Mach 0.7

Range: At least 20 km (11 nm)

DEVELOPMENT:

Development was initiated in the early 1960s at the Norwegian Defence Research Establishment in response to an assessment of Royal Norwegian Navy requirements. These two bodies and A/S Kongsberg Vaapenfabrikk have worked in close co-operation since the inception of the programme. Financial support, through bi-lateral agreements, has been given by the US and West German Governments. Technical and test support facilities have been provided by the US Navy.

Although originally designed for deployment on smaller naval craft, the Penguin system is well suited to use on larger vessels. It is also being considered for use in coastal defence and studies have been made of its use from helicopters. In the latter case, minor modifications only are stated to be necessary. Additionally, a modified version without the booster motor and with a smaller wingspan is being considered for use from jet fighters, but so far as is known, this project has not progressed beyond the study stage.



The Penguin missile

STATUS:

Operational in *Snogg*-class and *Storm*-class patrol boats and Oslo Class frigates of the Norwegian Navy, and on patrol boats of another country.

MANUFACTURER:

A/S Kongsberg Vaapenfabrikk, Postboks 25 – 3601 Kongsberg, Norway.

SWEDEN

2366.221

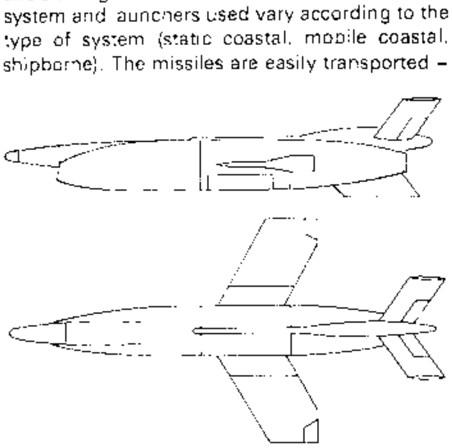
RB 08A

DESCRIPTION:

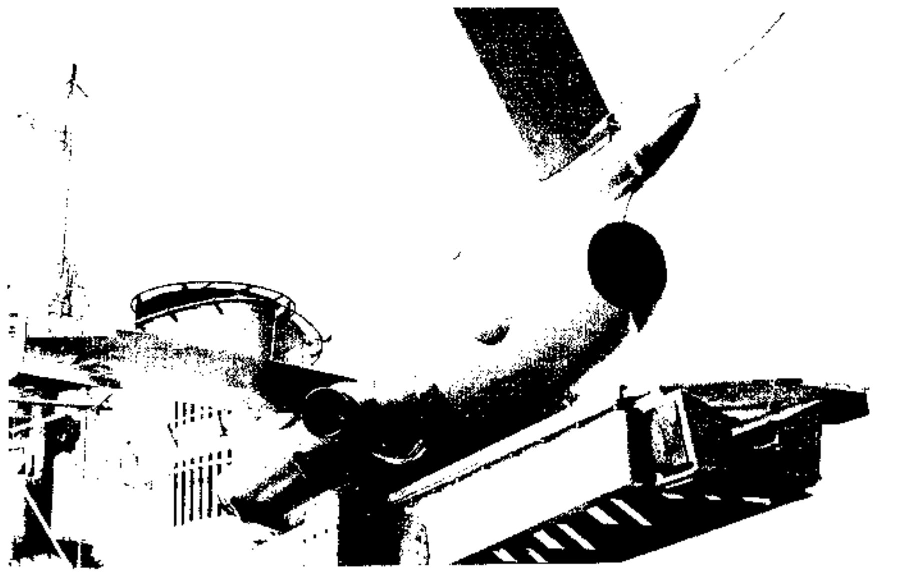
RB 08A is a surface-to-surface long-range cruise missile system intended for coastal defence and ship-to-ship use.

Based on the Nord CT 20 target drone, the missile is a rocket-launched turbojet-powered monoplane carrying a warhead large enough to destroy an average freighter. The complete system comprises the missile, the fire control system and starting box and the launchers; of these the missile and starting box are common while the fire control system and launchers used vary according to the type of system (static coastal, mobile coastal, shipborne). The missiles are easily transported – the wings fold – and the amount of other equipment required for a mobile battery is not great.

The range of the system is not disclosed, but it may be noted that the Nord CT 20 drone has an endurance of 60 minutes and a maximum speed of 900 kmn at 10,000 metres. Since the all-up weight of the RB 08 is considerably greater than that of the CT 20 and since the RB 08 has the same power plant as that version of the CT 20 to which the figures above refer, a substantial reduction in endurance must be expected; nevertheless it seems probable that the system range is more likely to be limited by other factors than by the range capability of the missile.



RB 08A



RB 08A cruise missile on a shipboard launcher

SYSTEM DESCRIPTION:

The target is detected (by radar or by other means such as patrol boats or reconnaissance aircraft) and the target data are sent to a fire control director assisted by a computer. On the basis of these data and missile performance, the computer gives orders to the launcher.

The missile is launched by a booster unit which separates when expended. After climbing and further acceleration the missile reaches cruising altitude and speed; the climb being interrupted at a pre set altitude which is then held by a constant altitude device. In the last part of the flight the missile is guided towards the target by the homing equipment.

AUTOPILOT:

The autopilot consists of a constant altitude device, a programmer, two free gyros, one rate gyro, a signal transforming head and logic circuits. Signals from the homing head, the constant altitude device and the gyros are converted to steering signals fed to the wing spoilers and the elevator actuator. Pitch demands are met by elevator movement: yaw demands are met by actuating the spoilers to roll the missile and then by elevator movement.

HOMING EQUIPMENT:

No details have been released concerning the operation of the homing equipment, but it seems likely that it is a radar operating in one of the higher frequency bands and capable of distinguishing between the target vessel and the surrounding sea clutter. The homing head is mounted in the nose of the missile; the warhead is mounted in the middle of the fuselage. It has been reported in France that homing heads for the RB 08A are supplied by Thomson-CSF.

CHARACTERISTICS:

Type: Surface-to-surface cruise missile system

Guidance Principle: Directional launch, followed by autopilot control, terminal guidance probably active radar homing

Power Plant: Turbomeca Marboré IID (400 kg static thrust) Booster rocket assembly for launch

Span: 3.01 metres

Length: 5.72 metres

Height: 1.33 metres

Missile gross weight: 900 kg

Booster unit weight: 315 kg

Total launch weight: 1,215 kg

HISTORY

Work on the RB 08 system was initiated by the Royal Swedish Navy and the first design study was carried out in 1959. There followed several years of development and investigation work, and then in 1964 Saab was appointed prime contractor for the system. RB 08 first went into service in Sweden in 1967.

Production of the weapon ceased in February 1970. It is understood that no successor system is planned.

MANUFACTURERS:

HARPOON SHIPBORNE SURFACE-TO-SURFACE MISSILE (RGM-84A)

DESCRIPTION:

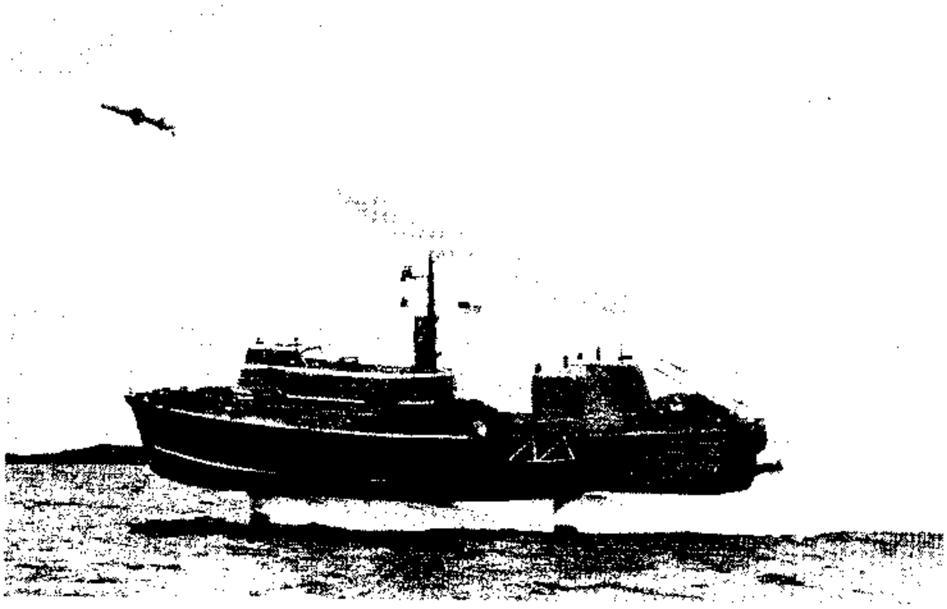
Harpoon (RGM-84A) a high-subsonic anti-ship tactical cruise missile which is being developed for the US Navy and which is expected to enter service in the mid-1970s.

This missile is officially regarded as the principal anti-ship weapon and has been designed for launch from all classes of USN surface ships (except patrol gunboats), the S-3 Viking and P-3 Orion maritime patrol aircraft, USN A-6 and A-7 attack aircraft, and in a special encapsulated form, from all but the oldest nuclear attack submarines. The airborne and submarine versions are described elsewhere in this book (entries **1301.221** and **2642.421** respectively) and the following description relates primarily to the shipborne version, although much of the system is common to all three applications.

An all-weather system, Harpoon has been specified in a way that is intended to achieve operational flexibility and adaptability to existing systems. The main body of the missile with its cruise-phase propulsion and guidance systems, homing and terminal manoeuvring systems, ECCM facilities and warhead is common to all applications; the aerodynamic surfaces of this part of the system exist in two forms, one of which will always be used for airborne and sometimes for surface launchings while the other will always be used on submarines but also for certain types of surface launchings.

For all other than airborne launchings an additional boost section contains a solid-propellant boost motor. This propels the missile on a ballistic trajectory which it follows until the booster separates: after which the missile descends to a low cruise altitude, determined by its altimeter, and flies to the target under the power of its turbojet cruise motor. In the terminal phase the missile executes a "pop-up" manoeuvre to evade close-in enemy defences and enhance the effectiveness of its warhead. Aerodynamic control throughout is by four movable fins on the main missile body.

The weapons control system for Harpoon AN/SWG-1(V), is produced by McDonnell-Douglas, with Sperry as subcontractor for the Command and Launch console. Targeting data are provided by a Command and Launch Subsystem, which interfaces with the missile-borne equipment to programme and launch the missile. The Harpoon Data Processor is a general-purpose digital computer which receives targeting and attitude data from standard shipborne equipment (or from a third party for over the-horizon operations) and computes the necessary missile and launcher orders. After launch, en-route guidance is provided by a missile-borne system consisting of a strap-down attitude reference assembly and a digital computer: no data inputs from the ship are required by the missile after it has been launched. Cruise altitude is monitored by a radar altimeter and flight control commands are interpreted by electromechanical actuators operating on the fins. This guidance system is designed to operate satisfactorily when the missile is launched at any angle up to 90° from the required course line.

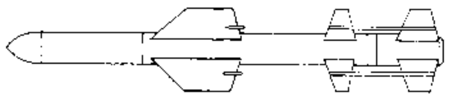


Harpoon launch from PCH-1, High Point, the US Navy's oldest operational hydrofoil. A series of test firings to evaluate a canister-type launcher/container was carried out in December, 1973 and January, 1974 at the joint Canadian-US range in Nanoose, Canada

Terminal guidance is achieved by means of a Texas Instruments DSQ-28 active radar homing system which maintains its lock until final impact. Included in the terminal guidance system is provision for the terminal manoeuvre referred to above: it should be noted, also, that the high degree of manoeuvrability implicit in this terminal pattern also means that the missile is capable of engaging targets that are taking high-speed evasive action. The radar homing system is frequency-agile, and this facility, coupled with extensive on-board computer logic circuitry, provides considerable ECCM capability to the missile in the terminal phase.

CHARACTERISTICS:

Type: Shipborne surface-to-surface tactical guided missile



Harpoon

Guidance Principle: Pre-programmed attitude reference plus radar altimeter in cruise phase; active radar homing

Guidance Method: By electromechanical control of four moving fins

Propulsion: Solid propellant booster. Teledyne CAE J402 turbojet cruise engine

Warhead: High-explosive blast type

Missile Length: With booster 4.57 m
Without booster 3.84 m

Missile Diameter: 34 cm

Launch Weight: With booster 635 kg
Without booster 500 kg

Range: Up to 60 nm (110 km)

LAUNCHERS:

Harpoon can be launched from Tartar, Terrier or ASROC launchers. In addition, however, a special Canister Launcher has been developed which will make possible the use of Harpoon on vessels (or coastal installations) where these standard types of launcher are not available. This type of launcher is, however, particularly aimed at providing Patrol Hydrofoil Missile (PHM) ships and other small surface vessels with a means of using Harpoon. Weighing some 900 kg, the launcher consists of a cluster of four Harpoon canisters, each containing one missile, and associated support structure. For use in these canisters the aerodynamic surfaces of the missile are modified to enable them to be folded within the diameter of the canister.

DEVELOPMENT:

The full history of this project can be traced back – as an air-to-surface concept – to about 1968. The idea of combining this with a ship-launched missile programme is much more recent. Requests for proposals were issued in January 1971; and in May of that year McDonnell Douglas Astronautics was selected as prime contractor and awarded a $66 million contract.

The project is now in an advanced stage of development. Successful launches have been made to demonstrate aircraft, surface ship and submarine capabilities. Entry into service is planned for the mid-1970s.

STATUS:

The weapon system development contract was awarded in June 1973. This provides for 40 prototype missiles and command and launch systems for P-3 and S-3 aircraft and a variety of surface craft. These are being used for test and evaluation work which started in early 1974. If a review of results proves satisfactory, pilot production will be initiated later in 1974. The Fiscal Year Budget allocates $58 million for development, $78 million for procurement of 150 missiles (58 for operational test and evaluation and 92 for the first operational deployment of Harpoon). 20 of the 58 test rounds are for use in Encapsulated Haproon development.

MANUFACTURERS:

Programme Direction: US Naval Air Systems Command supported by the Naval Ordnance Systems Command.

System Contractor: McDonnell Douglas Astronautics Company, 5301 Bolsa Avenue, Huntington Beach, California 92647.

Propulsion: Teledyne CAE (turbojet), Aerojet Solid Propulsion Co (booster).

Guidance: IBM, Lear Siegler, Texas Instruments.

Radar Altimeter: Honeywell

2669.221
INTERIM SURFACE-TO-SURFACE MISSILE (ISSM)

DESCRIPTION:

Initiated in 1971 as the Interim Surface-to-Surface Missile, but more recently referred to in official US quarters as the Standard SSM (Surface-to-Surface Missile) programme, this development was undertaken to provide an interim anti-ship missile capability until such time as Harpoon (**2641.221** above) could be developed and deployed. As the programme has progressed, three different versions of Standard have been involved, of which two were operational and the third was still in development in the first half of 1974. As a consequence, this version, Active Standard, is no longer regarded as an interim weapon as it is running concurrently with Harpoon which has the same function.

The first of the three, Standard SM-I-MR, has been installed in six DEG class ships and two Patrol Gunboats (PG) not previously missile-equipped. Thus, with the vessels already fitted with Standard in its original anti-aircraft role, a total approaching 100 have been given a limited anti-ship missile capability. Standard SM-I-MR employs semi-active radar homing so that range is limited to the radar range of the associated illuminating radar. For extension of operating range beyond the horizon Standard ARM (Anti-Radiation Missile) and Active Standard were initiated. The former, which is designed to home onto radiating sources on the target, is to be installed on 12 DDG-Class ships and four Patrol Gunboats.

Development delays with Active Standard have ruled out its use as an interim SSM weapon, and under the schedules applicable in early 1974 it could be introduced into USN Fleet service only a few months before Harpoon. Development of the latter, however, was not regarded as sufficiently advanced to justify cancellation of Active Standard and it was retained as a back-up to Harpoon. As its name implies, Active Standard employs an active radar homing head to provide for over-the-horizon operation.

1758.211
US NAVY CRUISE MISSILE

DESCRIPTION:

The USN Cruise Missile programme is also known as SLCM (Submarine-Launched Cruise Missile) since the principal aim of the project is to provide a long-range, penetration, cruise missile capability for US submarines, similar to that already available to Soviet submarines in the form of the SS-N-7. However, it is also proposed to provide for surface ships launching of SLCM, and the USAF is engaged in collaborative development with the USN in the project with the aim of producing an Air-Launched Cruise Missile (ALCM). Broad areas of responsibility allocated to the two Services are propulsion (cruise) to the USAF, and guidance to the USN.

The general capability called for by the Navy envisages two versions: a tactical model with a range of 300 nautical miles (555 km), and a strategic model with a maximum range of about 1500 nautical miles (2780 km). Nuclear or conventional warheads will be available for both versions. Turbofan engine propulsion for the cruise phase will be used and it is expected that the guidance system will embody the TERCOM (Terrain Comparison) technique pioneered by the USN. As an aid to penetration when used in the strategic or shore target bombardment role, a low-level cruise profile will be followed.

More details of this programme will be found in the section of this book dealing with Sub-surface-to-surface weapon systems (Entry No **1759.411**).

STATUS.

The US 1975 Fiscal Year Budget allocated a total of $45 million for SLCM development.

THE UNION OF SOVIET SOCIALIST REPUBLICS

2949.221
RUSSIAN NAVAL SURFACE-TO-SURFACE MISSILES

There is some uncertainty regarding the identification of some of the surface-to-surface missiles installed in Russian surface vessels and for use on some of their submarines when surfaced. In part, of course, the uncertainty stems from the general lack of information from official Russian sources – plus the suspicion that attaches to such information as does come from these sources – and much of the information that is available results from observation of and speculation regarding the activities of the Soviet Navy and the navies of the other Warsaw Pact countries.

An added complication, however, is the Russian practice of continuous weapon development and modification. All countries practise this to some extent; but in the USSR it seems that there is both a greater readiness to put an improved device into service, even on an experimental basis, and a greater willingness to keep older equipment in service than is apparent in most Western countries. Older equipment seems seldom to be withdrawn totally from service: it may be relegated to reserve formations or handed over to the armed forces of satellite nations; but so long as it remains operationally useful, to however restricted an extent, it is seldom scrapped. This is, of course, a perfectly sensible policy provided it is consistent with reasonable efficiency in manpower training – and here it seems likely that the very large numerical strength of the Soviet armed forces is an important consideration.

Like much other Russian military equipment the naval missiles are commonly identified in three ways – by an alpha-numerical code of US origin, by a NATO code-name and sometimes by some other name. The US code numbers appropriate to these missiles are SSN-1, SSN-2 etc. and it is known that missiles up to SSN-11 have been thus identified. For two of these missiles the NATO code-name is known with reasonable certainty: SSN-2 is Styx (**1155.221**), the missile that has for many years been carried by the "Komar" and "Osa" fast patrol boats, and SSN-3 is the naval version of Shaddock (**2976.221**) which is carried by some submarines and several surface vessels.

Most authorities agree that the NATO code-name for the SSN-1 is Scrubber (**2968.221**); but many identify it with the missile widely known by the non-NATO name Strela (**2986.221**). The balance of probability is inclined towards these two missiles being one and the same; but there is a slight discrepancy between their reported sizes, Strela being noticeably larger than Styx whereas Scrubber is said by some to be similar to Styx. The subject is more fully discussed in the entry for Scrubber.

2968.221
SCRUBBER SHIPBORNE SURFACE-TO-SURFACE MISSILE (SSN-1)

DESCRIPTION:

The SSN-1 cruise missile is the earliest known weapon of this kind deployed by the Soviet Fleet. Two code-names have been associated with the SSN-1, Strela and Scrubber, but on the evidence available, the latter is regarded as the correct NATO designation.

Little is known with any certainty of the precise dimensions or configuration of Scrubber beyond the fact that it has an aircraft-type layout and requires a launch ramp about 17 metres in length. This ramp is carried on a mount that can be trained over an angle of about 200 degrees and elevated. It is surmounted at one end by a 'hangar-type' enclosure, presumably used to house one missile in a 'ready-to-fire' state. To the rear of the launcher a deckhouse is located for the housing and preparation of reload missiles.

In 1973 two "Krupny" class destroyers remained in service with installations of this sort fore and aft, while four "Kildin" class destroyers were then in use with a single aft Scrubber installation.

The SSN-1 Scrubber is thought to fly at subsonic speeds and to carry a high-explosive warhead. The probable means of propulsion is by ramjet, with a solid-propellant booster rocket for the initial launch and acceleration phases. A maximum range of about 100 nautical miles (185 km) has been credited to Scrubber in some quarters, but the practical operating range is probably considerably less. If, as is generally assumed, command guidance by radio is employed for the cruise phase, the operating range could be extended by use of a co-operating aircraft. The "Krupny" destroyers carry their own helicopter, but the Kildins are not so equipped. Infra-red homing during the terminal phase is considered likely, although opinions on this differ and it is possible that alternative homing heads may have been developed during the long life of this weapon.

DIMENSIONS (PROVISIONAL):

Length: 7.6 m
Diameter: 100 cm
Span (Max): 4.6 m

STATUS:

Entry into service was in 1958-59 with "Krupny" and "Kildin" class destroyers of the Soviet Fleet. The numbers of these vessels fitted have decreased over the years as a result of conversions, and it is likely that the next year or so will bring the complete disappearance of Scrubber as an operational weapon.

SSN-1 Scrubber (Provisional)

1155.221
STYX SHIPBORNE SURFACE-TO-SURFACE MISSILE (SSN-2)

DESCRIPTION:

The SSN-2 Styx anti-ship missile is a short/medium range weapon which is very widely deployed by the Soviet Fleet and the navies of many of its allies. Entry into service was in 1959 or 1960, but despite the length of service this indicates, new Styx installations are apparently still being made. This weapon also has the distinction of being the first of its type to have been used operationally, in the 1967 war between Israel and Egypt, and more recently by Indian ships against Pakistan vessels in December 1971.

The general configuration is that of a small aircraft, with a delta planform wing and a triple tail-surface arrangement. A jettisonable booster rocket is used for the launch and acceleration phases, after which an internal motor sustains a cruising speed of about Mach 0.9. Range is estimated as about 20 nautical miles (40 km) maximum.

During the relatively long service life of Styx it is probable that several guidance modes have been employed, and some references quote the existence of 'A' and 'B' versions of the SSN-2 (but without agreement as to the differences between the two models). They probably relate to various combinations of the following alternatives: (1) the cruise phase could be carried out under either autopilot or radio command guidance, (2) the terminal phase could rely upon continuation of command guidance, active radar, or infra-red homing. Over the years, the launcher/hangars associated with Styx have undergone progressive changes and it seems reasonable to assume that the guidance apparatus also has received periodic updating, in which case all of the above methods may be employed in different installations.

DIMENSIONS (PROVISIONAL):
Length: 6.25 m
Diameter: 75 cm
Span (Max): 2.75 cm

STATUS:

Styx has been in operational service since 1959 or 1960 and is now widely deployed with Soviet Navy forces and those of numerous friendly states. Most widespread are the fittings on board the "Osa" and "Komar" Class missile boats which are operated by the navies of Algeria, Bulgaria, China, Cuba, Egypt, East Germany, India, Indonesia, North Korea, Poland, Romania, Syria, Yugoslavia, and possibly Pakistan, this last nation thought to have been supplied by China. Komar boats carry two launchers and "Osa" class vessels have four each. Exclusive of Chinese and Soviet figures, the above navies in 1973 had a total of 121 boats of both classes to produce a potential total of 348 Styx missiles. The Soviet Styx force in the same period comprised 25 "Komar" Class and 65 "Osa 1" Class boats to yield a total of 310 missiles. It should be mentioned that the Soviet Navy has 55 Osa II boats which each carry four Styx-type launchers of obviously later design and which are held to contain a newer missile designated SSN-11, about which little is known except that it performs a similar function to Styx and is of later design.

More recently, information has been received of a modified version of the Soviet Navy's "Kildin" Class of destroyer, which now has four launcher/containers of the same sort as those on the Osa II boats.

The People's Republic of China is another important user of SSN-2 and there is good evidence that after having been supplied with initial quantities of Styx missiles and Komar and Osa missile boats, the Chinese have now established their own production lines. Provisional figures (1973) for these amount to about 40 Komar type boats and up to 55 Osa I boats, yielding a potential total of 300 SSN-2 launchers. In addition, China seems to have been the first nation to add Styx to the armament of larger vessels. The new class of destroyers of indigenous design, but based on the Soviet "Kotlin" class in some respects, has two twin or triple launchers for what is almost certainly Styx (Chinese version) amidships. It has also been learned that at least one of the ex-USSR Pacific Fleet "Gordy" class destroyers has been equipped with Styx-type launchers in place of the original sets (2) of torpedo tubes. It is believed that a twin SSN-2 launcher replaces each torpedo mount. The same source has also reported that China has a number of Styx missiles deployed as coastal defence weapons.

SSN-2 Styx (Provisional)

2976.221
SHADDOCK SHIPBORNE SURFACE-TO-SURFACE MISSILE (SSN-3)

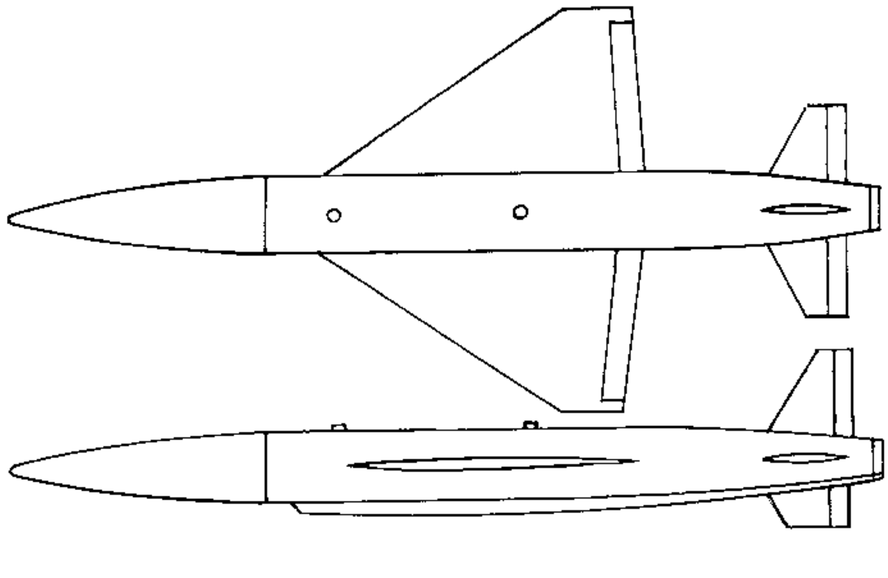
DESCRIPTION:

Shaddock is the largest of the Russian cruise missiles. It is not known to what extent, if any, the missile that is installed in many surface vessels and submarines of the Soviet Navy differs from the Shaddock missile displayed (in its container) at Moscow parades and used by Russian land forces (**2975.121**) but it is generally assumed that there are some differences: moreover it appears that there are several different missiles of the Shaddock type in naval use.

DESCRIPTION:

Powered by either a ramjet or a turbojet engine. Shaddock is boosted by two large JATO units under the rear of the fuselage. These give the missile a great deal of power at launch, and a notable characteristic of the missile's flight pattern is a very steep climb immediately after launch.

Command guidance is used; and for surface vessel installations the missile is tracked by Scoop Pair radar (**1324.253**) and course corrections transmitted to it by radio. For the terminal phase it is believed that infra-red homing is used; but it may be assumed with some confidence that this is



SSN-3 Shaddock (Provisional)

Shaddock missiles installed on Soviet W class submarine

one feature of the missile that will have been affected by modifications in the 10 years or so that these missiles have been in service, the most likely development being the provision of an active radar homing head.

Missile speed is believed to be transonic and range is limited mainly by radio/radar horizons. With mid-course guidance the maximum achievable range is believed to be about 300 nautical miles, but practical ranges are nearer to 100 nautical miles for missiles launched from cruisers and less than that for submarine-launched missiles.

It is believed that the standard warhead is nuclear with a yield in the kiloton range.

One of the most interesting aspects of this weapon system is the extent to which it has been installed in submarines and the length to which the Russian engineers have gone to find the most satisfactory form of installation. Of several types of submarine installation the most elaborate is the four-missile arrangement in the W-class "Long Bin" submarine (illustrated here) which involves the insertion of an additional section – about six and one-half metres long – into the submarine hull and constructing thereon a streamlined conning tower in which are built four forward-firing missile launchers, in two pairs both inclined to the horizontal by about 15 degrees.

STATUS:

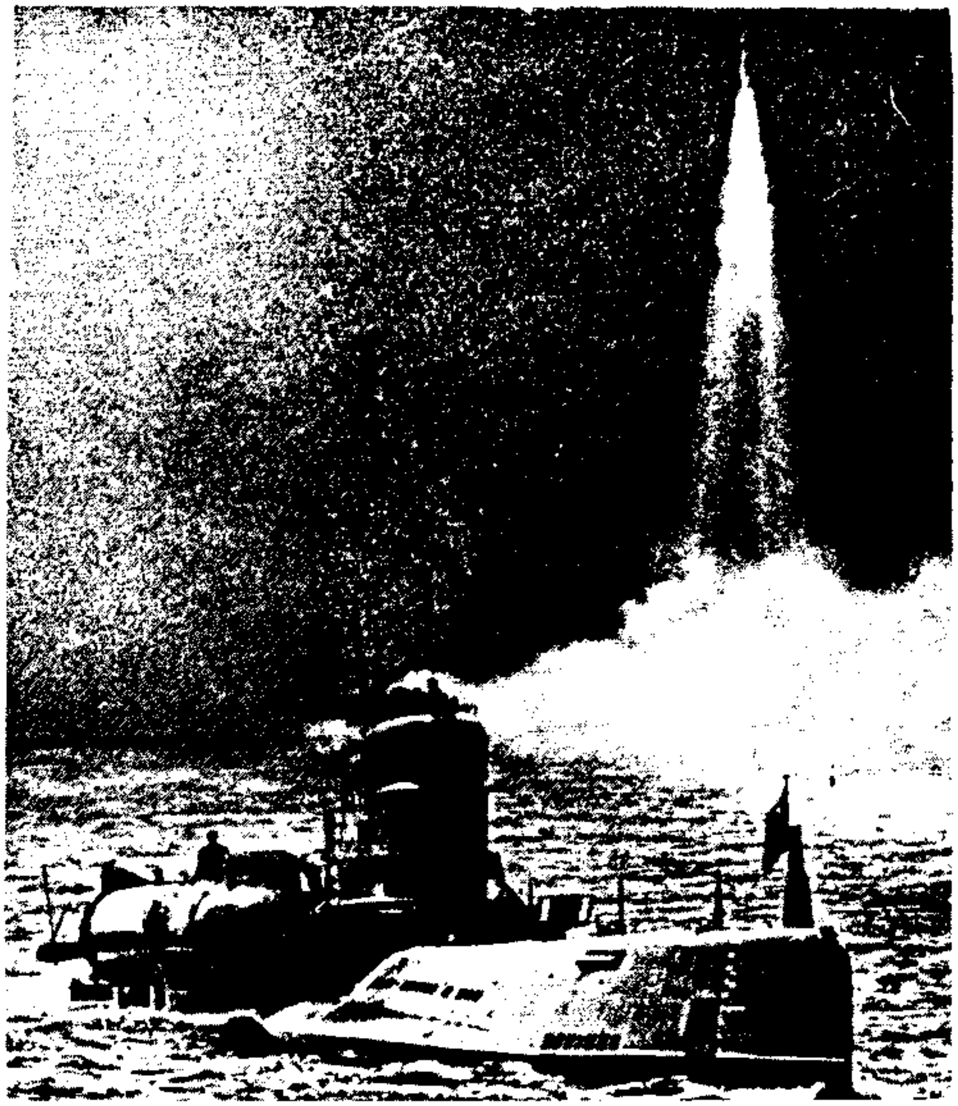
Shaddock-type missiles are installed operationally in "Kresta I" and "Kynda" class guided missile cruisers and in submarine classes E1, E2, J and W. The E1 and E2 nuclear submarine classes carry respectively 6 and 8 missiles in pairs, the launchers being let into the hull so as to present a smooth surface except when elevated for launching. The J-class non-nuclear submarines have similar launching arrangements for four missiles. In the W-class submarines two arrangements are still current – one being the Long Bin arrangement described above and the other the "Twin Cylinder" arrangement in which two launching tubes are mounted on the deck aft of the conning tower.

Each of the "Kresta" class cruisers carries four Shaddock-type missiles in twin launchers which can probably not be reloaded in action. The "Kynda" class carry two quadruple launchers fore and aft and probably carry eight further missiles with which to reload the launchers. The "Kresta" launchers and all the submarine launchers can be elevated for firing but cannot be trained. The "Kynda" launchers, on the other hand, can be trained through about 250 degrees and elevated up to about 30 degrees.

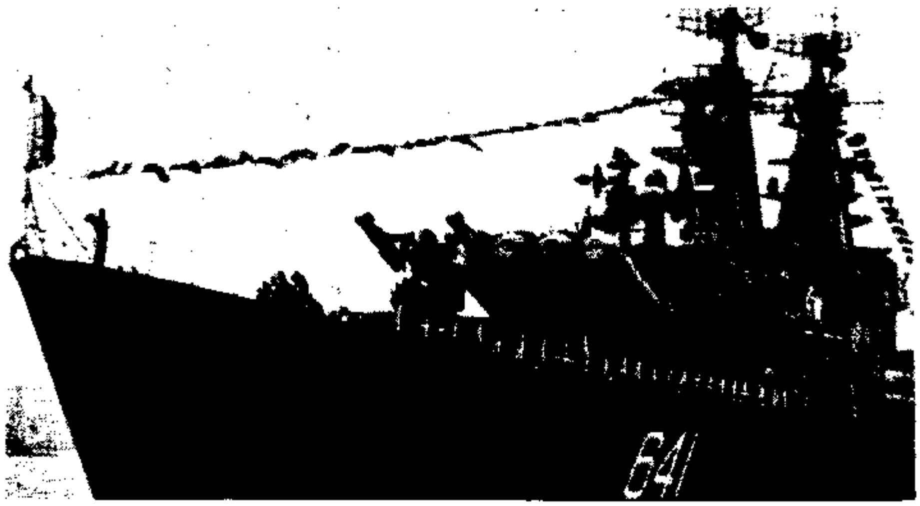
On the basis of the latest available figures for each class of vessel, the Soviet Navy has a total of 48 Shaddock launchers on surface ships and no less than 336 on submarines.

NONEMCLATURE:

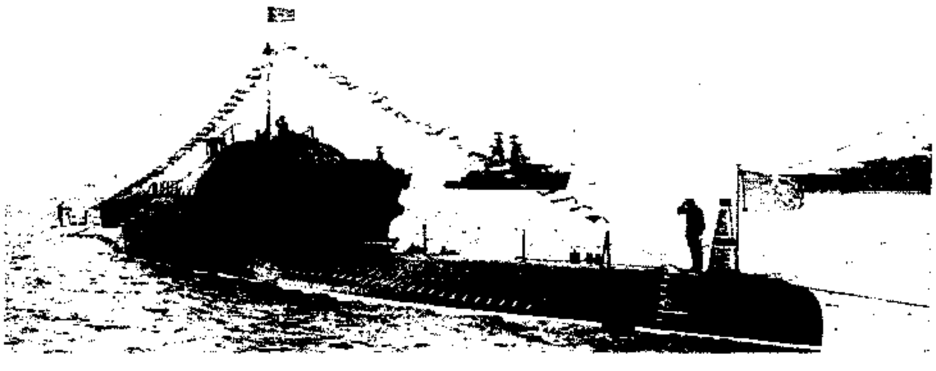
It seems to be generally agreed that the cruise missiles described specifically in this entry are those known in the American code as SSN-3, that they are about 12-13 metres long, and that they have a range capability (as noted above) of at least 300 nm (c. 550 km) and it has been suggested that the maximum range may be as much as 450 nm (c. 840 km).



W-class submarine with "twin cylinder" Shaddock missile launcher installation. Missile launch in background is probably Shaddock (NOVOSTI)

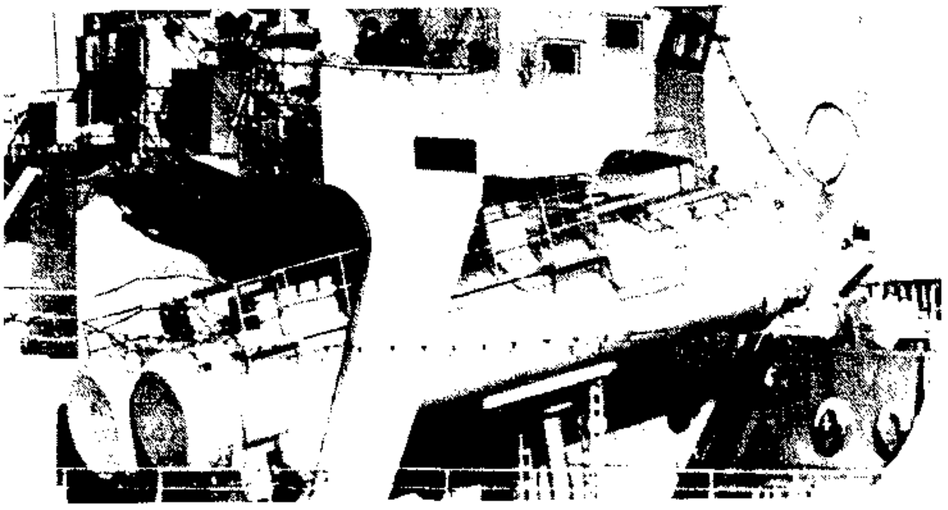


"Kynda" *class GM cruiser with quadruple Shaddock launcher* (NOVOSTI)



W class "Long Bin" submarine with enclosed Shaddock launchers. In the background can be seen a Shaddock-armed "Kynda" *class cruiser and the 150 mm guns of a Sverdov class cruiser* (NOVOSTI)

It can be seen from the accompanying illustrations, however, that the "Kresta I" and "Kynda" launchers are significantly different from those on the W class submarines — the "twin-cylinder" version of which resembles that of the land version of Shaddock (**2975.121**). According to one source, the "Kresta"/"Kynda" version is known as SSN-3B in the American code while the other is known as SSN-3A.



Shaddock launchers on a "Kresta I" guided missile armed destroyer (OFFICIAL US NAVY PHOTOGRAPH)

1760.221
SSN-9 SHIPBORNE SURFACE-TO-SURFACE MISSILE

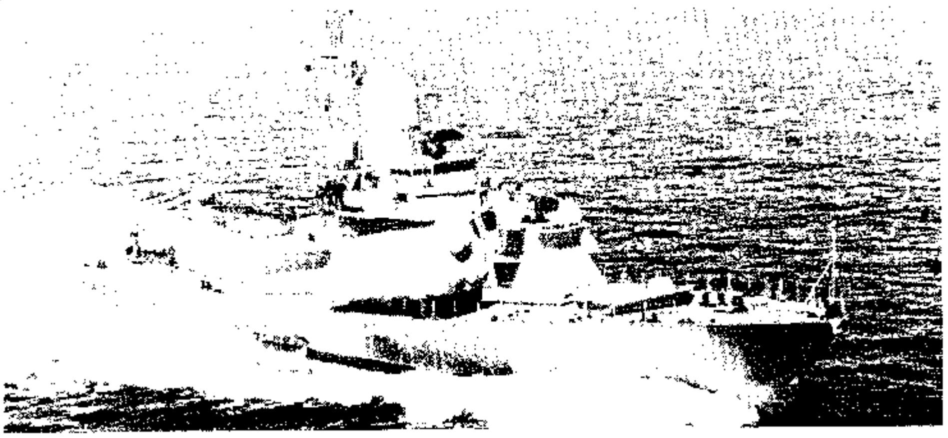
DESCRIPTION:

The designation SSN-9 has been allocated to the surface-to-surface missiles carried in the two triple launcher/containers aboard the Soviet "Nanuchka" Class missile boats which made their appearance in 1969. To date, no pictures or official details of the missiles themselves have been made public, and hence performance figures must be regarded as provisional. No other class of vessel has been definitely associated with the SSN-9, and neither has any NATO code-name for this weapon been made public. It has been conjectured, however, that the anticipated new "Papa" Class of Soviet submarine may employ SSN-9 or a derivative as its cruise missile armament, although the existing SSN-7 may be retained for this class of boat.

The estimated range of the SSN-9 is up to 150 nautical miles (about 275 km) with external mid-course guidance by co-operating aircraft or helicopter. A normal operating range of about 40 nautical miles (about 75 km) seems likely. Autopilot, with or without radio command link guidance, is the probable method of cruise phase control and active radar homing may be the normal terminal homing technique. The associated search and fire control radar group on "Nanuchka" Class vessels is reported to be code-named Band Stand.

STATUS:

Fittings so far confirmed are confined to the "Nanuchka" of missile boats, each of which has two triple launchers to give a total of 36 launchers at the end of 1973.



Soviet "Nanuchka" Class missile boat. Triple launchers on each side of bridge structure house SSN-9 surface-to surface missiles. Also to be seen is the lid of the retractable launcher for the new SAN-4 anti-aircraft missile system, on fore-deck (NOVOSTI)

1761.221
SSN-10 SHIPBORNE SURFACE-TO-SURFACE MISSILE

DESCRIPTION:

The designation SSN-10 has been allocated to the surface-to-surface missiles carried in new container/launchers fitted aboard "Kara", "Kresta II", and "Krivak" Class vessels of the Soviet Navy. As yet no NATO code-name for this weapon has been made public. Neither has any official data or any photograph of the missile itself, and therefore any published performance figures must be regarded as provisional. The SSN-10 is thought to have a cruising speed in excess of Mach 1 and a range of about 30 nautical miles (55 km) has been quoted, although compared with the maximum of 300 nm credited to the SSN-3 Shaddock which arms the older Kresta I ships this figure appears decidedly modest. It is thought more likely that the figure of 30 nautical miles might apply to the maximum autonomous range, ie when launched without the assistance of a co-operative aircraft for mid-term cruise guidance control. No reliable information as to the form of terminal homing used has been obtained, but the most likely candidate is active radar, possibly with an optional anti-radiation passive homing mode.

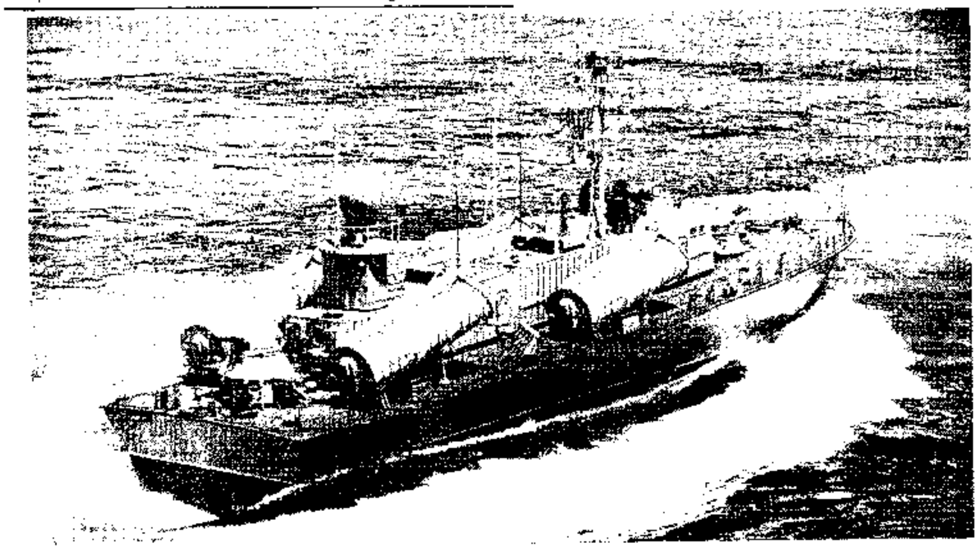
STATUS:

The SSN-10 became operational in 1968, and the latest available deployment figures show a possible total of 84 launchers. These are distributed as follows: six Kresta II with eight launchers; five Krivak's each with four; and two Kara Class light cruisers with eight launchers each.

1762.221
SSN-11 SHIPBORNE SURFACE-TO-SURFACE MISSILE

DESCRIPTION:

The designation SSN-11 has been given to the surface-to-surface missile carried in the new type container/launchers seen on the latest version of Osa missile boats of the Soviet Fleet. The missiles themselves have not been seen in public but are generally believed to be an advanced version of the SSN-2 Styx (**1155.221**). The performance is assumed to be similar in terms of range and speed, but the guidance techniques are expected to be more advanced. In addition to the "Osa II" Class vessels with which the SSN-11 was initially associated it has recently been learned that a modified version of the Soviet Navy "Kildin" Class of destroyer has been seen with four SSN-11 type launcher containers, two on each side of the after funnel, both pointing aft. It is possible that these have been installed as a replacement for the elderly SSN-1 Scrubber at one time seen on this class of destroyer. Two twin gun turrets have been fitted in the space vacated by the large Scrubber launch assembly.



"Osa II" *Class missile boat of the Soviet Fleet showing the four SSN-11 container/launchers* (NOVOSTI)

STRATEGIC AIR DEFENCE WEAPONS

THE UNITED STATES OF AMERICA

2574.131
ADVANCED BALLISTIC MISSILE DEFENCE

DESCRIPTION:

Complementing the long-standing ABRES programme of work on re-entry systems (**2709.111**) the US authorities have for some years been sponsoring programmes of work on ballistic missile defence techniques. Just as the ABRES work has from time to time become interlocked with specific ballistic missile development programmes so has the ABMD work overlapped with specific defensive system developments such as Safeguard (**2798.131**) and Site Defence (**2806.131**). In general, however, the programme has been concerned with problems rather than programmes and some of the areas of investigation are listed below.

Optical Techniques Both the aftermath of nuclear explosions and the ionized wake of hypersonic interceptors interfere with radar measurement and radio command guidance. Passive and active (laser) optical techniques of overcoming these difficulties have been studied.

Manoeuvring Interceptors Special techniques are required to cause a hypersonic interceptor to manoeuvre violently enough to intercept a manoeuvring re-entry vehicle. In Project **Upstage** two methods have been studied, each of which uses the aerodynamic forces on a missile of elliptical cross-section to aid a manoeuvre which is initiated either by burning a hypergolic fuel to part of the periphery of the missile base or by ducting a gas jet from an internally burnt propellant to provide the required turning movement.

Faster Interceptors Investigations aimed at improving on Sprint II (**2807.131**) performance by a factor of between 1.5 and 2.0.

Improved Components General investigation into improvement in sensors, hardened components and nuclear warheads.

Non-nuclear Warheads Apart from its cost andundesirable side effects, a disadvantage of the nuclear warhead for missile interception is that the authority of the US President is required before even defensive nuclear operations can begin. Various techniques for destroying incoming re-entry vehicles without recourse to nuclear warheads have been investigated – from simply strewing he predicted path of the missile with hard objects to the US Army's **HIT** programme (**2575.131**). Perhaps the biggest difficulty to be overcome in developing any non-nuclear warhead technique is that of devising adequate terminal guidance and manoeuvring systems – because a greater degree of precision is required for a successful non-nuclear interception than will suffice if a nuclear warhead is used, since the relative speeds of re-entry vehicle and interceptor warhead may be well in excess of 10 km/sec at the start of the terminal manoeuvre it is evident that fast and accurate pinpoint measurements will be required for success; and missile-borne laser radars are among the systems being considered.

STATUS:

Continuing programme.

MANUFACTURERS:

Various.

2575.131
HOMING INTERCEPT TECHNOLOGY (HIT) WARHEAD

DESCRIPTION:

Homing Intercept Technology (HIT) is the inelegant interpretation of a convenient acronym for a programme designed to provide an optically-guided non-nuclear warhead for an ABM missile. A potent reason for undertaking this development was the thought that a non-nuclear interceptor could be launched against a suspected hostile re-entry vehicle in an emergency without the need for Presidential authorisation of nuclear operations. Other factors were such known disadvantages of using nuclear interceptor warheads as the creation of radar blackout and interference with other (friendly) interceptors.

The HIT warhead comprises a combined propulsion and target destruction assembly and a guidance package. The latter consists of an optical sensor and a small digital computer and control mechanism, and round it is wrapped a cluster of small rocket tubes – the whole being spin-stabilised at a very high spin rate. The optical sensor detects the target and the computer controls the firing of the rockets so as to manoeuvre the warhead on an interception course. On close approach to the target the rocket rods are released in the path of the incoming vehicle to destroy it.

The warhead package is of sufficiently simple design to be suitable for economical mass production; and it was originally intended that several warheads, independently targeted, should be carried by a single Spartan missile (**2811.131**). Such multiple warhead arrangements, however, were specifically prohibited in the SALT 1 agreement and the US authorities have shelved the multiple-HIT programme for the time being. Instead, they are considering the installation of a single HIT warhead in a smaller missile. This is a much simpler proposition: the multiple warhead system would have involved the creation of a large missile-borne optical sensor to work in conjunction with ground control and to detect and identify the incoming re-entry vehicles and programme the HIT warheads to intercept them. With a single-warhead missile this large missile-borne sensor is not required.

STATUS:

Single-warhead system in development. Multi-warhead system shelved but could be reactivated if required.

MANUFACTURER:

LTV Aerospace Corporation.

2723.131
NIKE HERCULES AIR DEFENCE MISSILE

DESCRIPTION:

One of the earlier surface-to-air guided weapon systems still in commission, the Nike Hercules missile, successor to the Nike Ajax, is widely deployed in the USA and other countries. It first became operational in the USA in 1958.

Nike Hercules, a second-generation missile, possesses greater destructive ability and has a better performance than Nike Ajax. It has proved successful against high-performance aircraft at a variety of altitudes and has successfully intercepted short-range ballistic missiles and other Nike Hercules missiles in tests.

System units are a low-power acquisition radar, a high-power acquisition radar, a target tracking radar, or missile tracking radar, electronic data-processing equipment and remote-controlled launchers. A relatively recent introduction to the system, the high-power acquisition radar (HIPAR – **2499.153**), enables Nike Hercules mobile units to get the same full target detection capability as batteries at fixed sites. The HIPAR's three vans house radar gear transmitter, receiver and control equipment. One of its two semitrailers hauls the 43-foot-wide, fan-shaped antenna. The other semi-trailer carries power generators. Before the mobile HIPAR was adopted, more than 20 vehicles were required to move the radar system.

When a target is detected by the acquisition radar it is interrogated by the associated AN/TPX-46 IFF Mark XII interrogator and if adjudged hostile its location is transferred to the target tracking radar which pinpoints it for intercept purposes. The missile tracking radar issues guidance and burst orders to the missile.

Each Hercules battery can operate as a part of a defence network or as an autonomous unit, capable of detecting, tracking and engaging targets. The system operators are located in a battery control trailer, a tracking radar control trailer and a launcher control trailer. The Hercules is capable of operating in an electronic countermeasures environment.

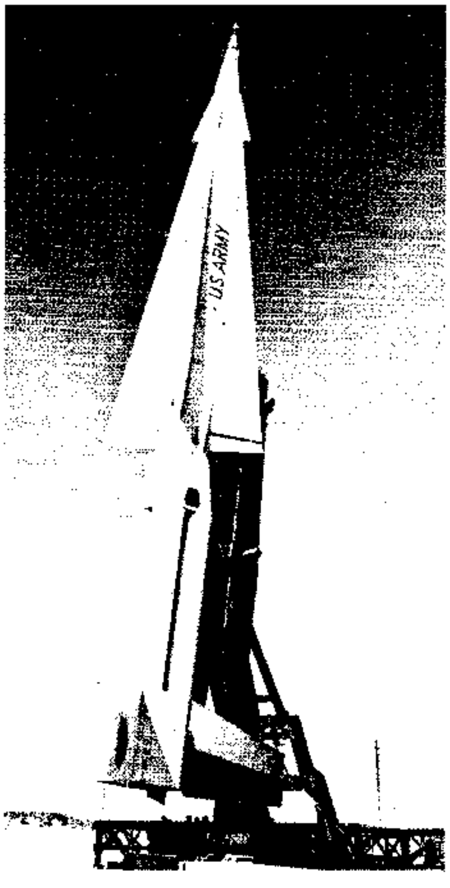
CHARACTERISTICS:

Type: Surface-to-air, strategic, guided missile
Guidance: Command
Propulsion: Two-stage solid-propellant rocket motor
Warhead: Nuclear or high-explosive
Missile Length: 12.5 metres
Diameter: 80 cm
Launch Weight: 4,500 kg
Speed: Supersonic
Range: More than 140 km
Ceiling: More than 45 km

STATUS:

Major improvements were made to this system in 1961 when new radars and modifications were added to enable the system to remain operational until replaced by the SAM-D missile in the mid-1970s. The number of active batteries has steadily declined since 1963, however, when there were 134 batteries. In March 1971 the Army ordered the inactivation of 27 firing batteries and 11 headquarters organisations and activities in 15 states by June 30. Included in the reduction were 16 active Army and 11 National Guard batteries. The cutback left only 13 operational batteries in the active inventory, with 27 other batteries manned by the National Guard.

It was announced in February 1972 that a further modification programme had started in 1971. This series of modifications was aimed at making the missile more manoeuvrable and better able to withstand ECM. The programme is going on at the White Sands Missile Range and suc-



Nike Hercules on launcher at White Sands proving ground, New Mexico cessful tests have been carried out close to specified limits of range and interception height.

A non-nuclear version of the Nike Hercules missile is being produced by Mitsubishi Heavy Industries Ltd for the Japanese Army under a licensing agreement with the American manufacturer.

Apart from Japan, Nike Hercules is also widely deployed in NATO and other countries with which the USA has friendly military relationships. Countries believed still to have the missile in strength are Belgium, Denmark, France, Greece, Italy, The Netherlands, Norway, South Korea, Taiwan, Turkey and West Germany. Until quite recently some of these countries still had small numbers of the earlier Nike Ajax missile. It is believed however that almost all of these have now been replaced.

In February 1974, the US Army announced that 48 Nike Hercules batteries within the continental United States would be de-activated and phased out by the end of 1974. Included among these were all the batteries manned by the National Guard. The decision, however, does not affect operational Nike Hercules units deployed with the US Army or overseas stations.

2798.131 SAFEGUARD ANTI-BALLISTIC MISSILE SYSTEM

INTRODUCTION:

Safeguard is the name which was given to the anti-ballistic missile (ABM) system proposed by the Nixon administration as a replacement for the five-billion-dollar Sentinel programme first announced in September 1967. The Safeguard proposal involved the deployment, at up to twelve sites, of long-range and short-range ABM missiles to provide a limited defence in depth against incoming ballistic or fractional-orbital bombardment missiles.

Whereas the original Sentinel proposals were for a comprehensive defence system giving substantial protection both to the civilian population and to the deterrent forces, Safeguard had more limited aims. Emphasis was placed on the protection of the Minuteman sites and only light overall protection of the population would have been provided even when all sites had been completed.

In making these proposals the US defence authorities were anxious to avoid giving the impression – especially to the USSR authorities – that they were seeking to alter the strategic balance. By proposing only limited protection for the major population centres – adequate perhaps to deal with a minor or accidental attack but totally inadequate to defeat a major attack – they hoped to make it clear that they were seeking only to protect their deterrent forces. Many experts at that time took the view that the development and deployment of ABM systems would have a destabilising effect on US/USSR relationships. This view is perhaps not so widely held today.

In August 1969 the US Senate approved, by only one vote, the Phase I deployment of the system, thereby authorising the commencement of construction work on two sites at Malmstrom AFB, Montana, and Grand Forks AFB, North Dakota.

The Phase II deployment authorised by Congress in December 1970 provided for construction of a third site near Whiteman AFB, Missouri; advanced preparation work for a fourth site near Warren AFB, Wyoming; and completion of Spartan and Sprint Missile inventories for the Phase I sites. The administration request to begin advanced preparation at four other sites was not approved.

For the Fiscal Year 1972 the administration proposed a programme which would either continue development at the Warren site or begin advanced site preparation for a site in the Washington, D.C. area, to protect the US National Command Authority (NCA). This approach was said to have been chosen in order to maintain sufficient flexibility in the programme in hopes of reaching an arms limitation agreement with the Soviet Union. Deployment would be limited to one of the two locations in the FY 1972 programme.

In November, 1971, Congress authorised continuation of the Grand Forks and Malmstrom deployments, advanced preparation at Whiteman and similar preparation at Warren. For the NCA system all that was authorised was the expenditure of some money on systems studies.

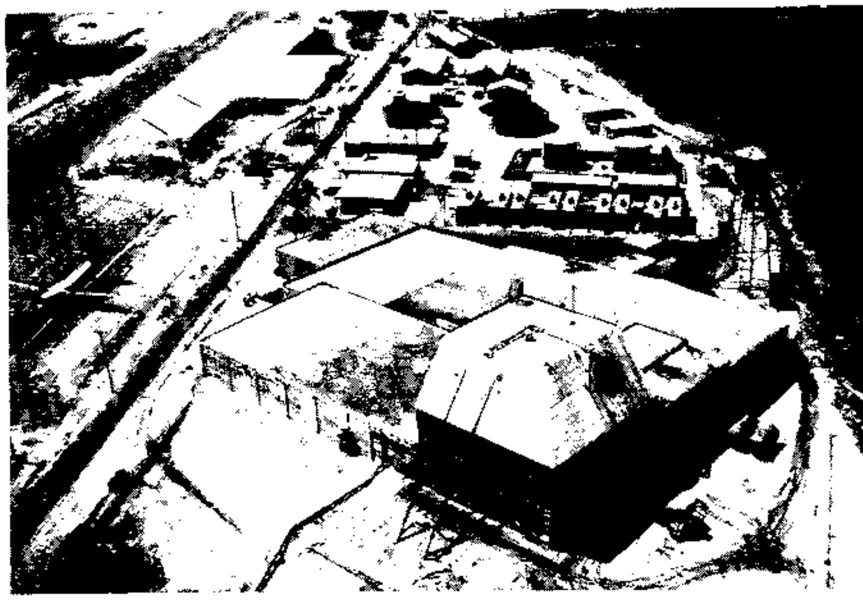
Following President Nixon's visit to Moscow and the USA/USSR ABM treaty, however, the whole Safeguard programme has been changed. Each country agreed to limit its ABM deployment to two complexes – one round the capital city and one other. For the USA the "one other" was the Grand Forks complex, which was about 18 months ahead of the Malmstrom complex in terms of constructional work, and on May 27th 1972 the US Secretary of Defense ordered the suspension of work at Malmstrom.

Whether a second complex will ever be constructed at Washington or not is unclear. At the height of US/USSR cooperation it seemed highly unlikely; and it is probably still unlikely – but now rather because a new approach to the whole problem of ballistic missile defence seems to be needed (see **2806.131**) than because it is not thought to be necessary to defend Washington.

SYSTEM DESCRIPTION:

Safeguard – and although the original project may have been reduced to a single ABM complex it is still both serviceable and convenient to retain the system name – incorporates two types of ABM defence called area defence and terminal defence.

The area defence system is capable of intercepting ICBMs, SLBMs and FOBS above the atmosphere at ranges of several hundred kilometres, and hence can protect large areas of the country, hundreds of kilometres across. A large, long-range radar, called the Perimeter Acquisition Radar (PAR – **2790.153**) detects and accurately tracks missiles at ranges of 1,500-4,000 kilometres. Based upon information from the PAR, a long-range missile (Spartan) carrying a warhead in the megaton range with a lethal radius of many kilometres is launched to intercept the incoming missile. Spartan (**2811.131**) is a slightly enlarged version of the earlier Nike Zeus missile and has undergone several successful flight tests at Kwajalein Island. A smaller radar, called the Missile Site Radar (MSR – **2791.153**), is located at the Spartan launch site and is used to steer the Spartan interceptor close to the incoming missile. A prototype of this radar has been operating at Meck Island in the Kwajalein Atoll since September 1968. It is said to have met or improved upon all its design objectives and with its associated computers has successfully demonstrated the possibility of ICBM interception.



Prototype Missile Site Radar on Meck Island, Kwajalein Atoll

Because of the large coverage from any one Spartan site only 12 sites would have been required to provide protection for almost all of the contiguous United States. The long-range radars would have been placed around the borders of the USA to provide for early detection of missiles coming from all directions. The MSRs and Spartan sites would then have been spread around the country to maximise protection of retaliatory forces as well as to provide area coverage of the country as a whole.

Such an area defence, however, has its shortcomings because it operates above the atmosphere. Very lightweight confusion devices such as chaff and metallic balloons can be distributed by an incoming missile. Nuclear warheads can also be deliberately detonated outside the atmosphere to create large regions of ionized gas which would be opaque to the long-range PAR radar for many tens of seconds.

How significant these shortcomings would be would depend on the ability of the potential enemy to exploit such confusion techniques – themselves necessarily the result of extensive research and development – and on the extent to which electronic counter-countermeasures (ECCM) had been developed by the defenders at the relevant time.

Granting that all reasonable ECCM steps would be taken, however, the views taken by the US proponents of Safeguard appear to have been, first that since the primary objective of Safeguard was the preservation of enough of the 1,000-Minuteman strategic deterrent force to be a credible deterrent even after a major ICBM assault, some penetration of the defences in such conditions would have been tolerable provided it were severely limited. Secondly, in the case of a major assault it was to be assumed that the primary objectives would be the retaliatory forces.

Assuming some penetration of the area defence system, therefore, the Safeguard proposal was for a second line of defence that would go into action after the effects of the confusion devices had been dissipated. Since only a few seconds would then remain before impact, however, this second line –

terminal defence – would have to employ a small and very fast interceptor missile. This missile (Sprint – entries **2812.131** and **2807.131**) exists and has been successfully tested. It operates in conjunction with the MSR which sorts out the confusion devices as the missiles come into the atmosphere and guides the Sprint to destroy the missile with its low kiloton-range warhead.

Because the radar must be close to the point where the missile comes into the atmosphere and since the response time is short, an MSR and Sprint site can protect an area only a few tens of kilometres across, and must be located near that area. In the proposed Safeguard deployment the Sprints were to be used to defend the radars themselves and the retaliatory missiles nearby.

The nuclear warheads of both Spartan and Sprint have elaborate safety devices to prevent them exploding at altitudes at which they would damage people or property below.

DEVELOPMENT:

As already noted, the prototype MSR began radiating power in September 1968 and has been operating ever since. Tracking of local targets was first accomplished with the MSR software in July 1969, and in December 1969 two ICBMs launched from Vandenberg AFB, California, were successfully tracked. The first PAR is being fabricated at the North Dakota site and is expected to become operational in October 1974. The USAF AN/FPS-85 radar, which is technologically similar to the PAR, has been operational at Eglin AFB since late 1968, and a limited engineering development model of the PAR was constructed at the General Electric plant at Syracuse, NY, during 1969.

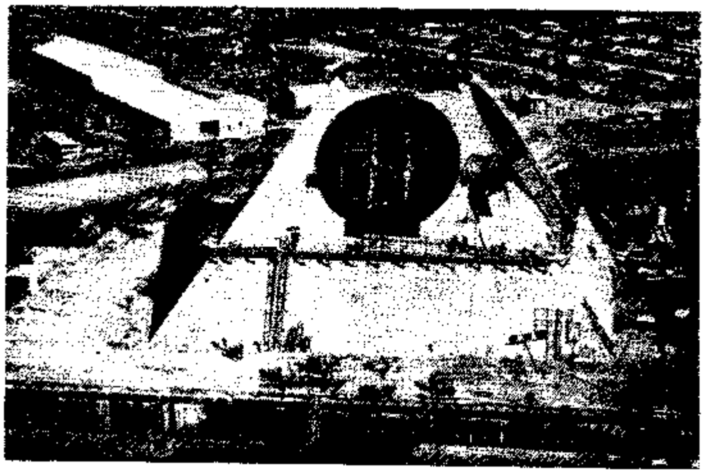
Integration of all major system components except the PAR was begun at Meck Island on Kwajalein Atoll in early 1970, and the first system test, which employed a Spartan missile, was conducted on April 14, 1970. By the end of 1973 there had been 49 system tests, of which 42 had been successful, two partially and five failures.

STATUS:

The Grand Forks site, with 30 Spartan and 70 Sprint launchers, one MSR and one PAR is scheduled to be completed in FY 1975. The equipment readiness date is, at the time of writing, still estimated as October 1974 and an initial operational capability is expected to be achieved in June 1975.

MANUFACTURERS:

Prime system contractor for development and testing is the Western Electric Company who are assisted by Bell Telephone Laboratories in engineering and design. Major component contractors are General Electric (PAR), Raytheon (MSR), McDonnell-Douglas (Spartan) and Martin-Marietta (Sprint). Subsidiary contractors are too numerous to list here but some additional details can be found under the entries for the individual system components.



Missile Site Radar (SR) and Perimeter Acquisition Radar (PAR) under construction at North Dakota sites. The SR (left) will have phased rays on each of its four sloping faces and will have a detection range of several hundred kilometres on a re-entry vehicle. The PAR building shown on the right is a kind intended to have only one phased array (on its sloping face): PARs proposed for some other sites would have had arrays on more than one face

2806.131
SITE DEFENCE

DESCRIPTION:

Formerly known as Hardsite (**2639.131**) and subsequently as SDM-Site Defence of Minuteman but now referred to in the USA simply as Site Defence (although we retain the SDM abbreviation for convenience), this is an ABM system that was originally conceived as a follow-on supplement to Safeguard (**2798.131**) which would be deployed only in response to an impending increase in the total ballistic missile threat to the USA beyond that which Safeguard was designed to meet.

Although the Nixon-Brezhnev agreement limits the total ABM deployment in the USA to two systems the SDM programme is continuing; partly as an insurance for the future (since, so far as the published texts of the Moscow agreement reveal, there is no ban on such developments) and partly because it is thought in some quarters that the SDM system will be superior to the original Safeguard system. It appears, indeed, that the provision in the Moscow agreements that permits the installation of up to 20 ABM radars at each site was insisted upon by the US negotiators specifically to permit the SDM programme to continue to the point of deployment if desired.

SDM components will include a small General Electric phased-array radar (**2792.153**) with a radiating aperture about one-fifth of the size of the Safeguard MSR radar, a Control Data Corporation 7700 computer subsystem, made up of two CDC 7600 computers, and an improved version of the Sprint missile known as Sprint II (**2807.131**). So far as is known the basic principle of operation of the system will be identical with that of the endo-atmospheric interception phase of Safeguard: the attractions of the system are understood to be improved missile performance and lower total cost – particularly of the radar sub-system. Performance requirements of the specified system components are all considered to be well within the state of the art: the important feature of the programme is the creation and demonstration of system capability; and there is consequently considerable emphasis on software development.

DEVELOPMENT:

The SDM programme was initiated in January 1971 and on June 3 a system engineering and technical assistance contract was awarded to Brown Engineering Company, Huntsville, Alabama, for $4 million. Six days later, contract definition awards of $2.5 million each were received by Hughes Aircraft Company, McDonnell Douglas Astronautics Company and Raytheon Company. On February 28, 1972, McDonnell Douglas was selected as prime contractor and awarded a five year, $382 million contract.

Contract definition for the Sprint II missile was completed in September 1971 by Martin Marietta Corporation and at mid-1972 that effort was in advanced design. On May 31, 1972, however, one week after the SALT treaty was signed, the US Army announced that Martin Marietta was being awarded a $168,360,000 cost-plus-incentive-fee contract for Sprint II development. The current estimate of total programme cost is $700-800 million to put the US authorities in a position to deploy the system in the late 1970s if they so wish.

Introducing an item of $160 million for this programme in the FY 1975 budget, the US Defence Secretary pointed out that not only would the programme lead to a Minuteman defence capability – should that be thought to be necessary – but it would also give the US the option of deploying a more advanced ABM system for NCA defence (Washington – see **2798.131**) if required.

STATUS:

Development. System integration testing scheduled to begin at Kwajalein, 1977.

2811.131
SPARTAN ANTI-BALLISTIC MISSILE MISSILE

DESCRIPTION:

Spartan is a command guided anti-missile missile powered by a three-stage, solid-propellant rocket and carrying a nuclear warhead. Now designated as the long-range element of the Safeguard missile defence system (**2798.131**), Spartan has been under development since 1965.

The missile will operate in conjunction with perimeter acquisition radar (PAR – **2790.153**), missile site radar (MSR – **2791.153**), computers and other support equipment.

Approaching missiles will be detected by the PAR (or in appropriate cases by BMEWS **2525.181**) and the MSR will be programmed to acquire them. The computer will calculate the best course for an interception and, provided such interception is possible, the Spartan missile will be launched from its vertical underground silo.

In flight the missile will be under command guidance, but the burning of the first two stages will be automatic, the second stage igniting as the first burns out and separates. The third stage, however, will not ignite automatically; ignition will be by ground command and will generally take place outside the atmosphere. This third stage is used for terminal manoeuvring followed by warhead detonation on command from the ground.

Designed for exo-atmospheric target engagement the standard Spartan warhead is believed to have a yield of five megatons – thus producing a hard X-ray energy density sufficient to destroy or disable incoming missiles over a considerable area by destroying their re-entry shields. More recently, however, a modified missile has been under development and this has a smaller and lighter warhead.

Improved Spartan

This new missile, so far known as Improved Spartan, is capable of greater acceleration and higher speed than the earlier model. Because of this it was seen to have several possible functions in the Safeguard system. First, its faster reaction makes it more suitable for the engagement of depressed trajectory ICBMs or low-altitude SLBMs for both of which the approach warning time may be substantially less than for an ICBM on a minimum-energy trajectory. Secondly, its greater range capability would have made it possible for Improved Spartans from one battery site to defend some of the area of an adjacent battery in the event of a saturation attack. Thirdly, while Safeguard deployment remained below the full 12-site configuration required for CONUS defence, the added range of the new missile was seen as a valuable system extension for protection against a light attack – such as might be threatened by China in the course of the next few years. The Safeguard programme changes necessitated by the USA/USSR ABM treaty obviously modify the validity of these reasons but they by no means extinguish it.

Improved Spartan, according to the US Defence Secretary, has been in Safeguard planning since the March 1969 Safeguard deployment announcement and plans until recently were and possibly still are to use a mix of the two missiles in the Safeguard system – the mix being dependent on the nature and direction of the threat envisaged. So far as is definitely known the basic missile is the same for both weapons, although it has been said that a modification is in development – the so-called "loiter" capability – whereby the motors are shut down for a brief period and then re-ignited on ground command after final target designation. The status of this particular development is not known, but it has been reported that the addition of the loiter capability involves a reduction in warhead yield from what is believed currently to be some 5MT to nearer 1MT.

DEVELOPMENT:

Development of Spartan started in 1965 and the first firing, from a concrete cell, took place in 1968. In April 1970 the US Army announced that the Spartan development test phase had been completed. Of the 15 test firings, 11 had been completely successful, two had been partially successful and two had been failures.

The first operational intercept test of the Safeguard system occurred on August 28, 1970, when Spartan launched from Kwajalein Atoll intercepted a Minuteman I modified test vehicle launched from Vandenberg AFB, California, 4,200 miles away. A prototype Missile Site Radar located and tracked the incoming nose cone and launched and controlled the Spartan to the intercept point outside the earth's atmosphere. Neither the Spartan nor the test nose cone carried explosive warheads, but the US Army announced that the test had been determined to be successful by ground instruments which indicated that the Spartan's final stage passed close enough to the target to have caused its destruction.

On January 11, 1971, two Spartan missiles controlled by a single MSR and launched seconds apart successfully intercepted targets. This was the ninth Safeguard system test and the first in which two interceptors were launched in a single test. One missile intercepted an ICBM nose cone while the other intercepted a fixed point in space.

CHARACTERISTICS:

US Army Designation: XLIM-49A

Type: Land-based silo-launched anti-ballistic missile missile

Guidance: Radar Command

Propulsion: 3-stage solid-propellant. Thiokol TX500 (225,000 kg st), TX454 and TX239

Warhead: Thermonuclear, believed 5 MT. Non-nuclear warheads have been considered – see entry **2575.131**

Missile Length: 16.825 m

Body Diameter: 107 cm

Fin-Span: 300 cm

Launch Weight: 13,000 kg

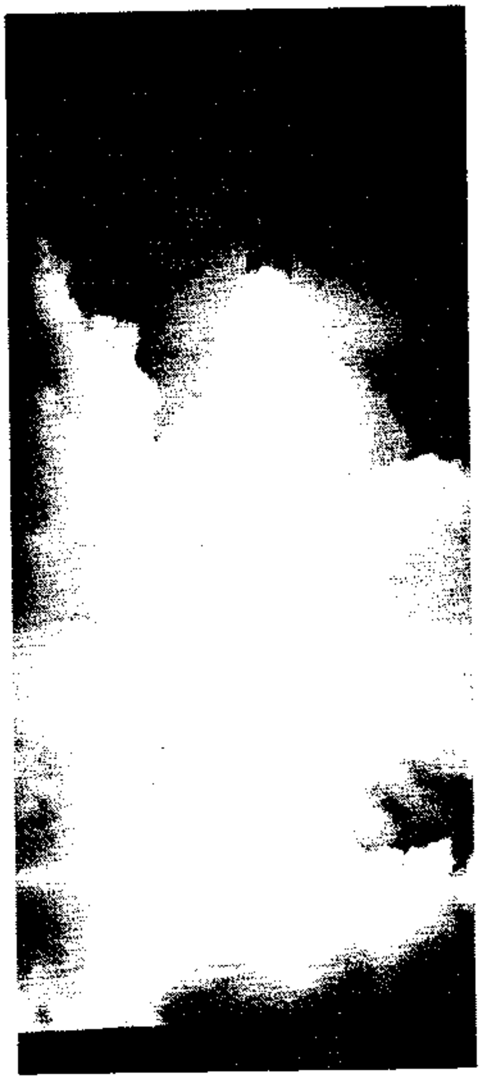
Max Slant Range: About 750 km

Max Engagement Altitude: About 550 km

Launch Reaction Time: About 30 sec

MANUFACTURERS:

Prime contractor for Spartan is Western Electric Company. Bell Telephone Laboratories have research and development responsibility; and McDonnell Douglas Astronautics, under the direction of Bell Telephone Laboratories, has responsibility for missile development. The rocket motors are by Thiokol Chemical Corporation and the missile-borne guidance system by Honeywell.



Spartan launch

2812.131
SPRINT ANTI-BALLISTIC MISSILE MISSILE

DESCRIPTION:

Sprint is a two-stage solid-propellant cone-shaped missile carrying a nuclear warhead and intended for use as an anti-missile missile. It is launched from an underground cell.

Originally conceived as part of the Nike-X programme, Sprint is currently serving as the terminal interceptor in the Safeguard ballistic missile defence system (**2798.131**).

A full description of the relationship between Sprint and the Safeguard defence system will be found under the Safeguard heading. Here it will suffice to say that the Sprint missiles, which form the second line of defence in the system and which will be targeted on such missile re-entry vehicles as constitute a threat to their defence area, are to be located at sites where there are also MSR **2791.153**) tracking and guidance radars. Warning of a threat will be given by PAR(**2790.153** long-range acquisition radar (which may or may not be co-located with the MSR) and the MSR and associated computing equipment will acquire and track the re-entry vehicle, calculate the interception trajectory and guide the missile to the interception.

Launched from an underground cell, Sprint is "popped up" by the ignition of a powder gas generator in the bottom of the silo. The gas propels a piston on which the missile rests and pushes the missile through the silo exit membrane, the piston being checked by a decelerator cage at the mouth of the silo. As the missile clears the silo its enormously powerful first-stage motor ignites and at the same time the missile tilts over in the direction required for interception.

During the burning of the first stage motor, the guidance commands from the ground are translated into course changes by fluid injection into the single nozzle. During the second stage flight the control is by aero-dynamic fins.

Warhead detonation is also commanded from the ground and is said to be intended to take place between 1,500 and 30,000 metres up. It is understood that incoming missiles are expected to be knocked out partly by simple blast and partly by the effect of high-velocity neutrons from the Sprint warhead on the fissile material in the incoming warhead: the neutrons cause it to deform and prevent it from detonating.

A complete interception takes about 15 seconds.

Sprint accelerating

CHARACTERISTICS
Type: Ground to air missile interceptor
Guidance: Radar command
Propulsion: Two-stage Hercules solid-propellant rocket motor. First stage approx 300,000 kg st
Warhead: Nuclear. Low kiloton range
Missile Length: 8.2 metres
Missile Base Diameter: 1.4 metres
Launch Weight: 3,400 kg
Range: About 40 km

DEVELOPMENT HISTORY:
The Orlando Division of Martin Marietta was selected to develop this missile in 1963 after a design study competition. The development at that time was part of the Nike X programme and Martin Marietta became a member of the Nike X team as sub-contractor to Bell Telephone Laboratories.

The first Sprint missile was successfully launched in November 1965 – less than three years after the first design study. Development testing was completed at White Sands Missile Range in August 1970.

The first system test utilising Sprint against an actual target occurred on December 23, 1970, when an ICBM target nose cone launched from Vandenberg AFB, California, was successfully intercepted. A development version of the system's MSR located and tracked the incoming target and launched and guided the Sprint to the intercept point. This was the eighth system test.

On March 17, 1971, two Sprint missiles launched less than one second apart successfully intercepted a Minuteman I nose cone. The missiles passed close enough to the target to have destroyed it if they had been armed with nuclear warheads. This was the eleventh system test and the first utilising two Sprints.

The first system test against a sea-launched missile occurred on May 7, 1971, when a Sprint intercepted a Polaris warhead over the Pacific. The Polaris, which follows a trajectory very different from that of the Minuteman warheads used in previous system tests, was launched from the USS Observation Island, a Navy missile test-firing ship.

The first series of sixteen system tests ended in the Autumn of 1971. Twelve of these tests were completely successful, two were partially successful and there were two failures.

A second series of system tests started in mid-1971 and ended in December 1973. There were 32 tests in this series, making a total of 48 system tests from the Spring of 1970 to the end of 1973. Of this second series 29 tests were completely successful.

STATUS:
In October 1973, it was announced that a $125.5 million contract had been awarded to the Western Electric Company for continued production and installation of Safeguard to the end of September 1974.

Martin Marietta's share of this contract for Sprint production is $18.4 million.

MANUFACTURERS:
Missile system: Martin Marietta Corporation, Orlando Division, Orlando, Florida.
Rocket Motors: Hercules, Inc.
Motor Cases: Brunswick Corporation.
Injection Valves: Ling-Temco-Vought.
Launch gas generator: Aerojet General.
Guidance and Control: Honeywell Inc., Western Electric.

2807.131
SPRINT II ANTI-MISSILE MISSILE

DESCRIPTION:
Currently under development by the Martin Marietta Corporation, Sprint II is an improved version of the Sprint ABM missile used in the Safeguard ABM system. Sprint II is destined to be the interceptor missile in the Prototype Demonstration Programme for Site Defence (**2806.131**).

Sprint II improvements over Safeguard Sprint include greater accuracy, greater manoeuvring capacity (three times that of the earlier missile), increased reliability, hardening and strengthening against nuclear blast and manoeuvre stress, and a faster launch process.

DEVELOPMENT:
In May 1971, the Martin Marietta Corporation received a $1.5 million US Army contract for a contract definition study of Sprint II to determine technical modification requirements, estimate costs and prepare schedules. This four-month contract was followed in October by a design contract for some $2.5 million for advanced design work on the new missile project.

In March 1972, it was stated by the Safeguard System Manager, Lt-General W.P. Leber, that Sprint II was in the advanced design stage and that this stage was scheduled for completion by 30th May 1972. On 31st May, Martin Marietta signed a $168 million contract with the US Army for the development and flight testing of the prototype interceptor. This contract was placed after and in accordance with the SALT Moscow agreement and had an anticipated duration of 57 months with an initial funding of $14.4 million.

STATUS:
Development. System integration testing with prototype radar and data processor is scheduled to begin at the Kwajalein missile range in 1977.

MANUFACTURER:
Martin Marietta Corporation, Orlando Division, Orlando, Florida.

THE UNION OF SOVIET SOCIALIST REPUBLICS

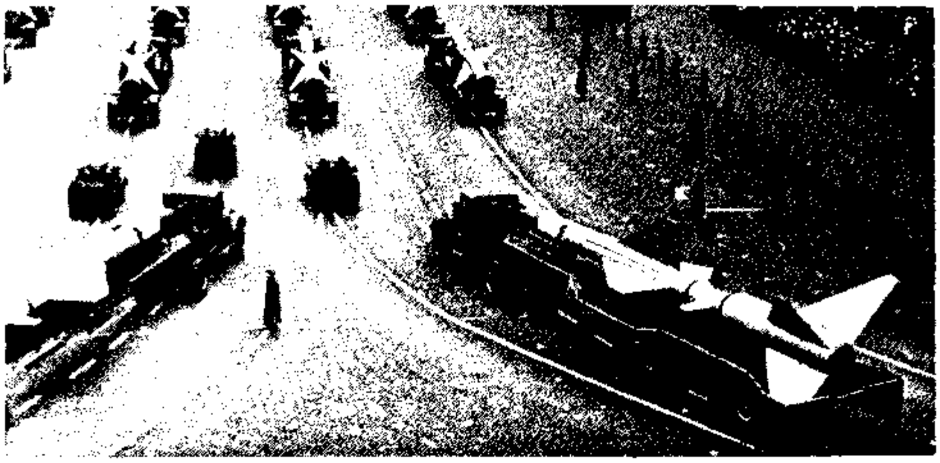
2940.131
SA-5 (GRIFFON) LONG-RANGE AIR DEFENCE MISSILE

DESCRIPTION:
Griffon is widely accepted as the NATO code name for a large surface-to-air weapon first displayed in public in 1963. It is also widely believed to be the missile known in the US alphanumeric code as the SA-5. Griffon has been variously described as an unmanned long-range interceptor, an anti-aircraft missile and an anti-missile missile, but it seems probable that although it may have some anti-missile capability it is primarily suitable for long-range anti-aircraft operations.

The nose of the missile houses a radar reflector of at least 60 cm diameter which can be combined with an active radar target seeking system.

Generally similar in size and weight to the US Nike Zeus missile, Griffon is thought to be somewhat inferior in performance and to have a smaller anti-missile capability. The fact that it is evidently manoeuvred aerodynamically indicates that its ability to home on to targets travelling at missile speeds must be very limited.

Although the missile evidently has two stages, it has been suggested that it may in fact have three – the third being a motor built into the warhead section and used to power the warhead and homing system during the final stages of interception.



Griffon missiles preceded by Guild missiles in the November parade in Moscow in 1963 (Novosti)

CHARACTERISTICS:
Type: Long-range surface-to-air guided missile
Guidance Principle: Radar homing
Guidance Method: By control of moving control surfaces on wings and tail
Propulsion: 2- or 3-stage solid-propellant
Missile Length: 16.5 metres
Missile Diameters: Booster: 1.0 metres
Second stage: 0.8 metres
Launch Weight: About 10,000 kg
Range: About 250 km
Ceiling: About 29 km

STATUS:
Operational – there are believed to be some 900 in service. For further discussions of Russian ABM and air defence systems see entries **2899.181, 2945.181** and **2989.181**.

2932.131
SA-7 (GALOSH) ANTI-BALLISTIC MISSILE MISSILE

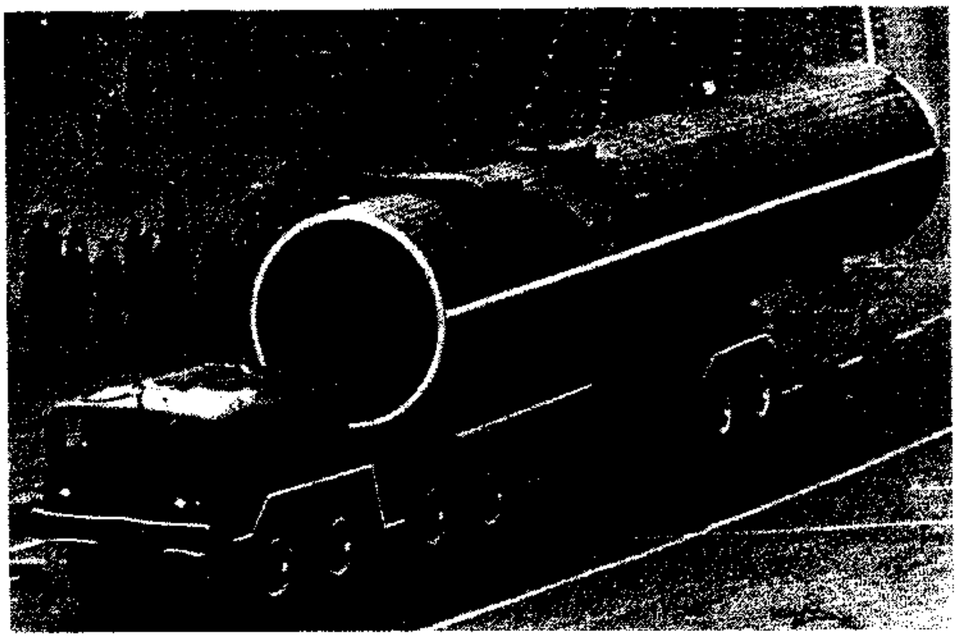
DESCRIPTION:
Galosh is widely accepted to be the NATO code name for the Soviet anti-ballistic missile missile, first "shown" to the public in 1964 and known as SA-7 in the US alphanumeric code. Since the missile has so far only been thus "shown" housed in an almost all-enveloping container little is known about it, other than that it has four first stage nozzles and that the container is some 20 metres long and has an internal diameter of about 2.75 metres. Soviet pictures purporting to show the launch of a long-range ABM missile that could well be Galosh have been seen; but they convey little information other than that the missile is more or less conical in shape.

It is believed, however, that Galosh carries a multi-megaton warhead suitable for exo-atmospheric missile interception and that it has a range of at least 300 km. On this assumption it is somewhat inferior to the US Spartan missile; moreover the giant "Henhouse" and "Doghouse" radars (**2864.153** and **2879.153**) with which it is associated for early warning and control are thought by some to be inferior in performance to the new phased-array radars of the US Safeguard system – the Henhouse radar was first observed in the late 1950s. These views are by no means generally accepted, however, and in some quarters it is thought that both missile and radars are in many respects superior in performance to the corresponding elements of the American Safeguard system.

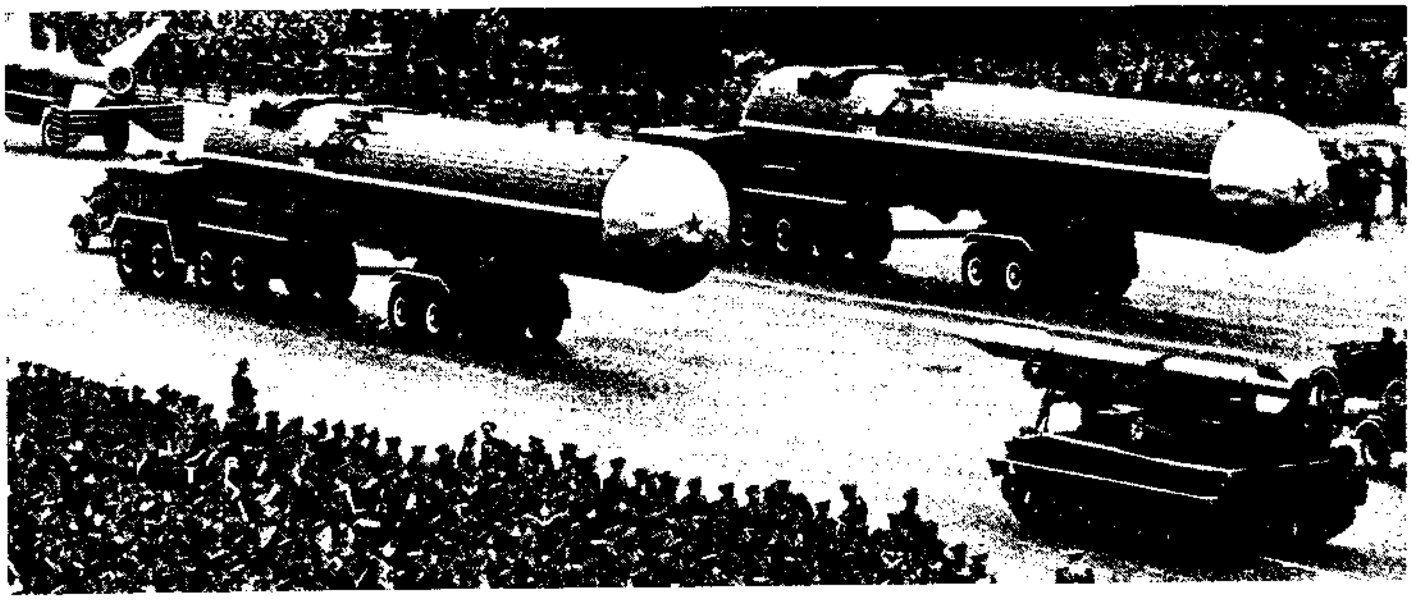
Moreover, Galosh is an operational system. There are reported to be 64 launchers in a system in the region of Moscow; and it is considered that with known system components these are capable of providing a "thin" defence of the capital. Because deployment slowed in 1968 it was at one time thought that the Russian authorities were abandoning the idea of ABM defences: it now seems, however, that the slowdown was associated with a reconfiguration of the radar system to take account of the potential threat from China and with improvements in the ABM system itself. These improvements have included the development of an improved missile (**2933.131**) – which is said to have a "loiter" capability similar to that mentioned in connection with Spartan (**2811.131**) – and a new and improved tracking radar.

CHARACTERISTICS:
Type: Surface-to-air anti-ballistic missile missile
Guidance Principle: Radar command
Propulsion: Probably 3-stage solid-propellant
Warhead: Multi-megaton nuclear
Missile Length: About 20 metres
Range: Estimated in excess of 300 km
STATUS:

Operational at Moscow in four sites containing a total of 64 launchers. Further deployment limited by ABM treaty and it is reported that the Russians are taking up their option of installing a further 36 missiles in the Moscow region – but which of the two versions of Galosh will be installed is not known. For further discussion of Russian ABM and air defence systems see entries **2899.181, 2945.181** and **2989.181.**



Galosh anti-missile missile (Novosti)



Galosh missiles in the 1966 May Day Parade in Moscow (Novosti)

2933.131
IMPROVED GALOSH ANTI-BALLISTIC MISSILE MISSILE

DESCRIPTION:

As noted in entry **2932.131** above, the Russians are reputed to have developed an improved version of the Galosh ABM missile, an important feature of the new development being a "loiter" capability.

At first, it was thought that this added capability was simply a way of improving the missile's exo-atmospheric interception capability. Recent reports of a fairly detailed nature, however, suggest that the new missile differs in function from the earlier one as well as in performance. Whereas the basic Galosh missile is believed to be a high-altitude exo-atmospheric interceptor, the new version – while still retaining a slant range capability of some 200-400 nm (350-700 km) – can stop and start its motor four or five times at upper altitudes – while decoys are sorted from warheads by the ground radars – and make a high-altitude interception in the re-entry vehicle's terminal phase.

STATUS:

Flight tests have been reported from American sources but otherwise the status is unknown. Since it appears that the Russians are in process of taking up their option of deploying 36 more ABM missiles in the Moscow area to make up the total of 100 launchers permitted by the SALT 1 agreement, it may well be that they plan a missile mix of the two versions of Galosh.

2935.131
NEW ABM MISSILES

DESCRIPTION:

There have been references, in several official statements from the US Department of Defence in the past year or so, to the development of two new Russian ABM missiles. No details of developments specifically identified with these references have come to our notice: it seems probable however, that the "Improved Galosh" missile (**2933.131**) is one of them and that it may also be the "new long-range ABM missile" that has been referred to by some other commentators.

We have no information on the second development: but since the most obvious omission from the Russian strategic missile inventory is a high-performance short-range interceptor like the American Sprint (**2812.131**) it seems to be at least a plausible speculation that the unidentified development programme relates to a missile of this type.

That the Russians should not have developed such a missile at an earlier stage in their ABM programme is not very surprising. The successful development and operation of a short-range, "last-ditch", endo-atmospheric interceptor requires, as a minimum, a highly sophisticated missile-borne electronic and electromechanical package which must also be extremely light, high performance microwave phased-array radars and elaborate data-processing facilities and a missile propulsion system with an enormous thrust-to-weight ratio. It is known that Russian technology still lags behind that of the Americans in microelectronics and in phased-array radar techniques (although they have narrowed the gap considerably in recent years) and, having regard to the manner in which they have bludgeoned their way into the space and missile business with giant launch vehicles, it seems likely that their knowledge of high-performance rocket motor technology is also some years behind that of the Americans. It may well be that they have only recently reached a point at which it would be reasonable to undertake the development of a Sprint-type missile.

LAND-MOBILE SURFACE-TO-AIR WEAPONS

2290.131
INTRODUCTION

Described in this section are weapons having a wide range of sizes and performance capabilities. All are suitable for use against hostile aircraft, and a few also have an anti-missile capability. All are to some extent mobile, and some are man-portable, but some of the larger systems take several hours to bring into action and are better suited to a semi-static defence role – e.g. of airfields or base installations – than to operations in defence of forward units.

Among the more recently developed systems there has been a noticeable emphasis on fast-reaction short-medium range weapons for defence against low-flying aircraft and tactical missiles; there have also been interesting developments in man-portable weapons capable of giving infantry units a degree of self-protection against aircraft attack that they have never previously known.

For convenience of system comparison, these mobile systems have been subdivided into three sub-sections – one dealing with mobile (but not portable) guided weapon systems; one dealing with mobile gun and rocket systems; and a third dealing with portable guided missile systems. While the first and third sub-sections are concerned with guided weapons which can be unambiguously distinguished from unguided weapons, there is some difficulty in defining the border between self-contained AA gun systems – which are described in the second sub-section below – and associations of AA guns with separate fire control systems. While we have endeavoured to follow a consistent line here, the reader may find it useful to consult "Land-based Anti-Aircraft Fire Control Systems" later in Section One and the ordnance entries at the beginning of Section Three.

MOBILE SURFACE-TO-AIR GUIDED MISSILE SYSTEMS

CHINA (PEOPLE'S REPUBLIC)

2050.131
CHINESE ANTI-AIRCRAFT MISSILES

Little is known about Chinese developments in the anti-aircraft missile field. It is known that they possess a number of missiles supplied to them by Russia before the two countries became estranged, and according to US statements these are all SA-2 Guideline missiles (**2942.131**).

Some of these Guideline missiles have in turn been supplied by China to Albania and installed in missile sites constructed under Chinese supervision. It was at one time suggested that some such sites, as yet unequipped, would be receiving Chinese-developed missiles, but there has been no further news on the subject for a long time. It seems clear, however, that the Chinese must be manufacturing Guideline missiles at least, because according to US reconnaissance reports several hundred of the missiles had been deployed in China by mid-1973. The US official view is that this deployment will continue for a few years yet: on the other hand the magnitude of the effort that is thought to be involved in the ICBM development makes it seem unlikely that much effort could be spared for new surface-to-air missile development.

FRANCE

2074.131
CROTALE LOW-ALTITUDE GROUND-TO-AIR MISSILE

DESCRIPTION:

Crotale is a completely automatic short-range surface-to-air missile system for the all-weather interception of low-altitude targets. The complete weapon system can be mounted on wheeled vehicles, semi-mobile launchers or shipboard launchers and is air-transportable.

Mounted on wheeled vehicles, the complete system comprises up to three combined launch and command guidance vehicles and a surveillance radar vehicle. Four missiles, in containers, are carried by each launch vehicle, the missile being in ready-to-fire condition. Also carried by this vehicle is a monopulse fire-control radar capable of guiding two missiles simultaneously, missile tracking being aided by a transponder mounted on each missile. Radar acquisition of the missile immediately after launch is aided by infra-red detection of exhaust heat: there is also an optical tracking device. Guidance signals are transmitted to the missile by radio.

On the second vehicle is a pulse-Doppler S-band surveillance radar having the good anti-clutter performance necessary for low-altitude target detection. Associated with the radar is an automatic target evaluation system that gives the weapon system its fast reaction time. Up to three launch vehicles can be served by a single acquisition vehicle.

DESCRIPTION – ACQUISITION UNIT:

On the surveillance radar vehicle is mounted a Thomson-CSF radar. This S-band equipment has an accuracy of target designation that is consistent with the requirements of the tracking radar on the other vehicle while permitting the high data renewal rate resulting from an antenna rotation rate of 60 rev/min. Two stacked beams make it possible to extract height information from the radar data and a sub-clutter visibility of 60dB gives the radar good performance on low-flying targets.

Associated with the radar are an IFF interrogator-decoder, a non-saturable extractor, a real-time digital computer, a display console and a digital data link (optional radio or cable). The computer, which is identical with that used in the firing unit, is used for the generation of synthetic video symbols and for the continuous processing of the system's twelve track-while-scan loops – the latter being used for the generation of accurate data for target designation and for confirmation of threat evaluation.

Crotale Acquisition Unit

The operational console consists of a PPI and an operation panel. On the PPI is displayed a synthetic video picture (computer generated) of the air situation together with threat indications (level of threat, initiated targets, IFF response) and a video map showing the locations of the firing units.

Initiation of the track-while-scan loops is either automatic – if the radar-computer combination considers that a threat is urgent – or manually by operator's joystick control. On initiation a push-button corresponding to the loop is illuminated, the computer triggers the IFF interrogator and the final result of threat evaluation is displayed by a signal lamp associated with the push-button.

Also on the console is an operation panel on which are signal lamps indicating the status of the firing units, three "fire designation" push-buttons, whereby the operator may assign the selected track-while-scan loop to one of the firing units, and three further push-buttons whereby the operator may order destruction in flight of the missiles in case of a late IFF recognition.

Data transmission to the firing units is by digital link either by cable (up to 400 metres) or by radio (from 50 to 5,000 metres). Target designation data and operational orders are transmitted to the firing units and information on operational status is received from them.

A crew of not more than two is required to man the acquisition unit – a chief operator, an assistant operator if required and a driver. The vehicle is of a "semi-cross-country" type and is electrically propelled. This method of propulsion results in reduced vibration levels and flexible driving; it also permits sealing of the vehicle for NBC protection. Electrical power is provided by a thermal motor driving an alternator and each wheel of the vehicle has its own electric motor. A hydraulic circuit provides for power-assisted steering, breaking, vehicle suspension and automatic levelling by jacks. Finally the vehicle is, of course, air-conditioned.

FIRING UNIT:

A Ku-band ecartometric monopulse radar is used with this part of the system. This is mounted concentrically with the launcher turret, which carries four missiles, and can track one target and guide two missiles simultaneously towards the same target. Other units in the vehicle include an X-band telecommand transmitter, an infra-red gathering system, a television tracking system for standby use, a real-time digital computer, an operating console and a digital data link.

Radiation from the radar is circularly polarised and is in frequency diversity. The use of Ku-band makes the achievement of a 1.1 degree beam-width possible despite the small dish size. The infra-red gathering system has a field of view of $\pm$ 5 degrees to enable it to generate missile/radar axis angular deviation data during the pre-guidance phase. The standby television system is for optical tracking if for some reason radar tracking is impossible.

Identical with that used in the acquisition system, the real-time digital computer is used, first, to make parallax corrections to the target designation data and to put the radar on target. It also computes the possibility of interception – to avoid wasting missiles – generates guidance orders during both the gathering and guidance phases, orders the arming of the missile's proximity fuse when it is nearing the target, orders the destruction of the missile if necessary and notifies the end of the engagement.

The operational console of the firing unit is designed primarily for supervisory purposes – so that the operator can supervise the status of the unit – and undertake its maintenance – and supervise the firing sequence in normal conditions. Provision is made, however, for him to intervene if necessary. An A-scope display enables him to check target and missile tracking, and manual radar and firing controls are provided. If the television system has to be used, of course, the operator will track the target manually.

Apart from changes necessitated by the different superstructure the design of the firing unit vehicle is generally similar to that of the acquisition unit vehicle.

MISSILE:

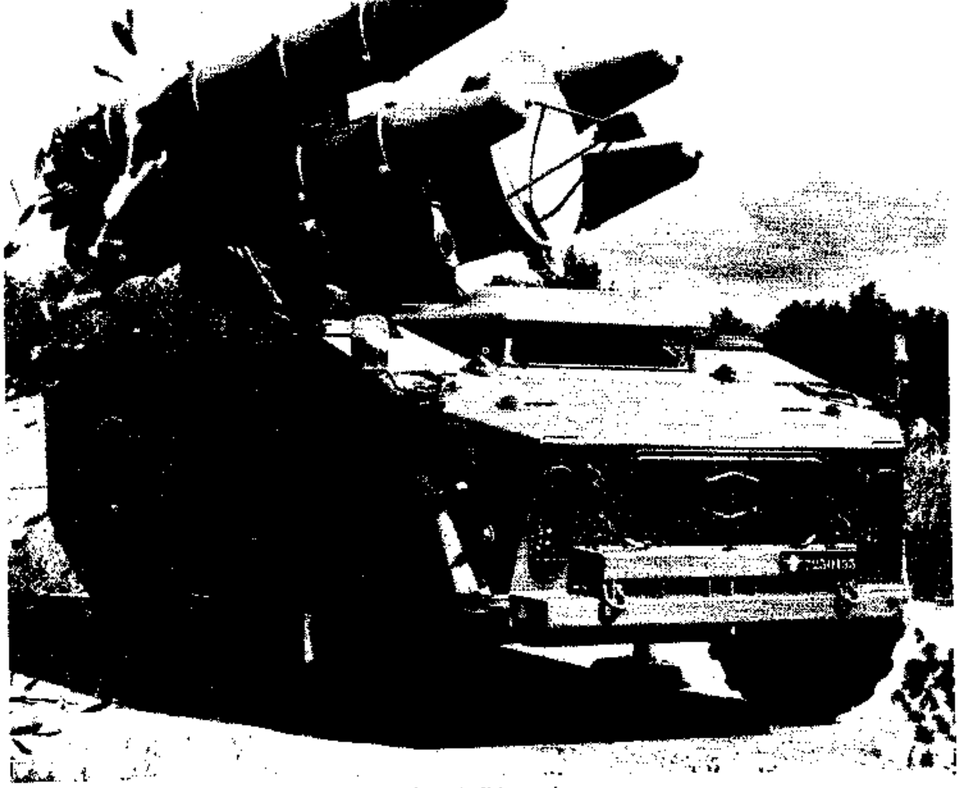
A canard configuration gives the missile great manoeuvrability and it is roll-stabilised by rear control surfaces for high-precision guidance. Its 15 kg warhead is detonated by an infra-red proximity fuse and produces a high-velocity (2,300 m/sec) directed fragmentation burst that is effective up to 8 metres. The warhead is armed by ground command through a telecommand receiver which also receives the guidance commands and, if appropriate, the destruct command. The telecommand receiver also triggers the transponder that the missile carries to make location easier.

Servo motors operating the control surfaces, controlling yaw and pitch at the front and roll at the rear, respond to the demands of an autopilot unit comprising three rate gyros and a gyroscope.

Propulsion is by a single-stage solid-propellant rocket motor that accelerates the missile to Mach 2.3 in 2.3 secs.

MONOVEHICLE SYSTEM:

Crotale's modular assemblies can be regrouped to form a single vehicle installation if required. For example, an arrangement of this kind on an AMX-30 tank chassis would permit the carriage of four missiles (as usual) on the turret with a reserve of a further four carried inside the tank. Reloading time for an arrangement of this kind would be 20 seconds.



Crotale firing unit

CHARACTERISTICS:

Type: Land-mobile, automatic, all-weather, surface-to-air guidance weapon system

Guidance Principle: Command guidance by digital radio link

Guidance Method: Infra-red missile gathering; secondary radar missile tracking by target tracking radar; command control of missile control surfaces via autopilot

Propulsion: Single-stage solid propellant motor

Warhead: 15 kg, high-explosive, directed burst, fragmentation type with infra-red proximity fuse

Missile Length: 2.89 metres

Missile Diameter: 15 cm

Span: 54 cm maximum

Launch Weight: Approx 80 kg

Speed: Mach 2.3 reached in 2.3 secs. 16 sec time of flight to 8 km

Typical Target Data:
Speed: Mach 1.2
Altitude: 50 to 3,000 m
Manoeuvre: 2 g
Radar-cross section: 1 sq metre, fluctuating

Performance Against Typical Target (0.9 interception probability):
Maximum engagement range: 8.5 km
Minimum Range: 500 m
Maximum crossing range: 3000 m

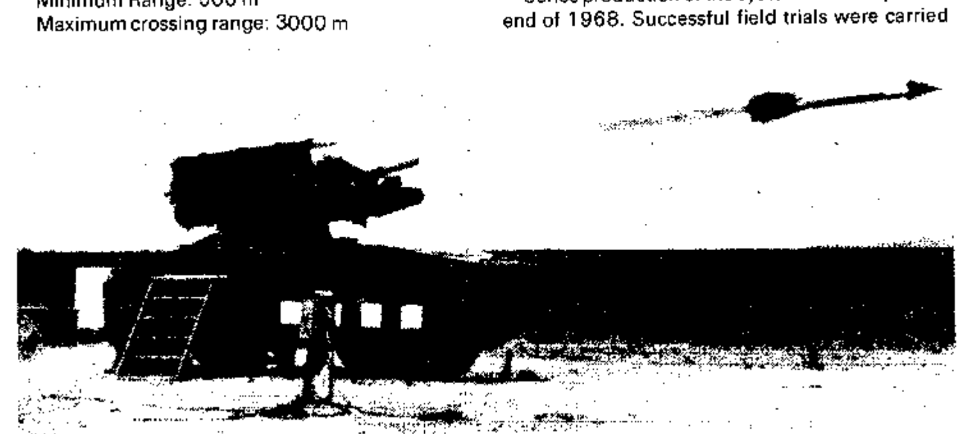
Crotale Acquisition Unit prepared for air transport

Reaction Time: 6 seconds from first detection to missile launch

DEVELOPMENT:

Work started on the project in 1964 both at Thomson Houston and Engins Matra and a prototype missile was completed in the following year. Over-all responsibility for the development lies with the Division Systèmes Electroniques of the Thomson-CSF group – while full responsibility for the missile lies with Matra.

Series production of the system started up at the end of 1968. Successful field trials were carried



Crotale firing

out at Landes, and deliveries to the South African forces began towards the end of 1971. The French Air Force ordered a quantity for the first part of an airfield defence network associated with their strategic nuclear forces. The system has also been discussed with various NATO countries.

In November 1970 Thomson-CSF were awarded a contract for nearly $1.5 million for a Crotale evaluation programme in the USA. Testing has been carried out at White Sands Missile Range and reports have been good. From the point of view of the US Army Missile Command, Crotale is a contender for its low-altitude Forward-area Air Defence System (LOFADS) which is intended to replace the Chaparral (**2542.131**) system in the late 1970s. Other contenders are the Franco-German Roland system and the British Rapier.

TEST AND TRAINING EQUIPMENT:

An automatic 3rd-echelon test bench has been made by Thomson-CSF in co-operation with Engins Matra.

SETAC – a tactical training simulator – is made by Thomson-CSF.

MANUFACTURERS:

Thomson-CSF, 1 rue des Mathurins, 92222-Bagneux.

Engins Matra, ave Louis Breguet, 78-Velizy.

INDIA

2287.131
INDIAN SURFACE-TO-AIR MISSILES

According to a report published in the Indian press, the Indian Government has made an agreement with the Russian Government whereby the latter will supply SA-6 (Gainful – **2930.131**) and SA-7 (Grail – **2941.131**) anti-aircraft missiles to India together with information to enable these missiles to be manufactured in India.

No details of this agreement are available – in particular it is not known whether the SA-6 production arrangement covers only the missile system or extends also to vehicles – but the arrangement is in keeping with that negotiated with France for anti-tank missiles (**2289.111**) and with the provisions of the new Indian Five-Year Plan.

MANUFACTURER:

Not definitely known, but almost certain to be Bharat Dynamics Ltd, Hyderabad, who make the anti-tank missiles.

INTERNATIONAL

2213.131
HELIP – HAWK IMPROVEMENT

DESCRIPTION:

HELIP is an acronym for Hawk European Limited Improvement Programme and refers to a programme of work on the modernisation of the American Hawk missile (**2640.131**) that was being undertaken in NATO countries. The object of the programme was to make a more robust version of the missile for introduction into service in 1976.

This programme now appears to have been superseded by a more far-reaching agreement between Raytheon and other concerned US manufacturers and the governments of, and appropriate manufacturers in, Denmark, France, Greece, Italy, the Netherlands and West Germany. This covers a programme of work amounting to some $750 million to bring the European Hawk missiles and supporting equipment up to Improved Hawk standards – including the provision of AN/TPX-46 Mk XII IFF equipment from Hazeltine and conversion of AN/TPQ 21 simulators to AN/TPQ-29 simulators by conversion kits supplied by Applied Devices Corporation.

MANUFACTURER:

Prime US contractor, Raytheon Company.

2292.131
MIFLA SURFACE-TO-AIR WEAPON SYSTEM

DESCRIPTION:

Mifla is understood to be the designation of a surface-to-air weapon project now under study as an international venture in Britain, France and West Germany.

No details of target specification have been released but it is understood that the operational requirement is for a system similar in general concept to the American SAM-D (**2800.131**) but less elaborate and much cheaper. It is worth noting that whereas the three countries have, jointly and severally, created three anti-aircraft weapon systems to counter the low-level air threat (Crotale, **2074.131**, Rapier, and Roland, **2218.131**), none of them has a current programme for a longer-range weapon. To some extent, no doubt, the decision to investigate the Mifla project was encouraged by the successes scored by the Russian SA-6 missiles (**2930.131**) in Egypt and Syria during the 1973 Arab-Israeli war. It has indeed been reported that the French authorities were considering the unilateral development of a similar system.

STATUS:

Project.

MANUFACTURERS:

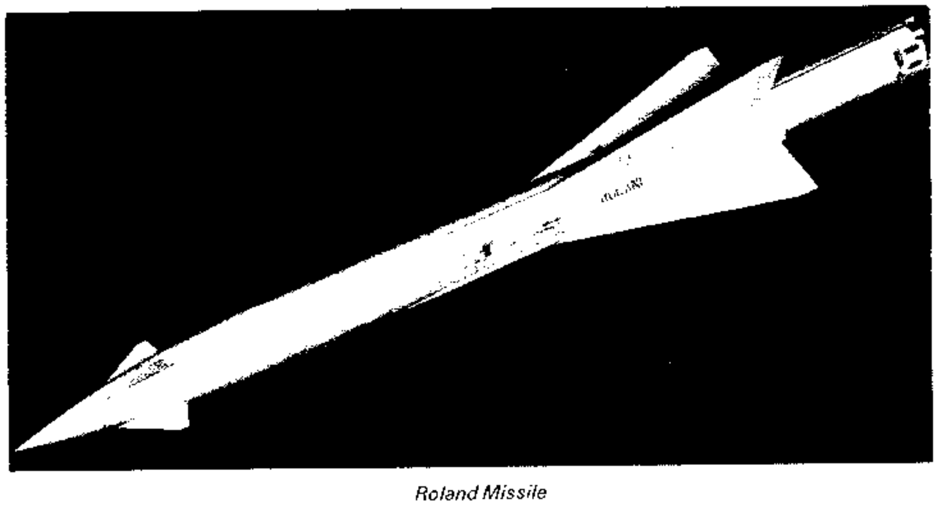
Not yet known.

2218.131
ROLAND MOBILE ANTI-AIRCRAFT WEAPON SYSTEM

DESCRIPTION:

Roland is a surface-to-air missile system intended to provide protection for highly mobile armoured fighting units against attack by low-flying aircraft. The system has the same degree of mobility, armour-plating and ABC protection as the units that it is designed to protect. A crew of three is all that is required to operate the system – commander, aimer and driver.

The complete system is carried on a tracked launch vehicle and in its first-phase configuration comprises a target acquisition and identification radar sub-system, an optical infra-red tracking and guidance sub-system and a launcher with missiles. The launcher is loaded from magazines of missiles carried in the vehicle by a hydraulic system that lifts a new missile into position each time one is fired.



Roland Missile

In its second phase (Roland II) configuration all the sub-systems listed above are retained so that the second-phase system can be operated in exactly the same manner as the first – but an accurate target tracking radar is added to enable the system to be used in visibility conditions that make optical target tracking impossible. Additionally, the possibility of switching from automatic to optical tracking even while the missile is in flight provides a useful counter-countermeasures facility.

CHARACTERISTICS:

Type: Land-mobile surface-to-air weapon system, using tube-launched guided missile

Guidance Principle:

Roland I Command to line-of-sight with optical aiming and automatic infra-red tracking

Roland II As above but with automatic radar aiming

Guidance Method: Jet vane missile control by command microwave radio link

Propulsion: Two stage (booster and sustainer) solid-propellant rocket motor

Warhead: High-explosive with proximity fuse

Ammunition Round:

Length: 2.6 metres

Diameter: 28 cm

Weight: 75 kg

Missile Length: 2.40 metres

Missile Diameter: Body: 16 cm. Span: 50 cm

Launch Weight: 63 kg

Cruising Speed: Approx Mach 1.6

Range: 500-6 500 metres

Radar Range: 15-18 km

Weight of Firing Unit: 6 tons

All-up Weight in SPz or AMX30: 32 tons

OPERATION:

Target detection in azimuth and IFF identification is performed by a pulse-Doppler surveillance and search radar on the launch vehicle, with a range of 15-18 km.

The weapon system commander is also the operator of the acquisition radar. He selects the target and, in the **Roland** I configuration directs the optical sight to the target azimuth. The aimer then searches in elevation and acquires the target, whereupon a missile may be launched. After launch the aimer maintains his aim and the missile is gathered to and guided along this track by an infra-red guidance technique (TCA) which is described in more detail in the entry for HOT **(2212.111)**.

Details of the acquisition radar have not been made public, but judging by the appearance of the scanner, and the operational data that have been released, it seems likely that the radar is generally similar to the Thomson-CSF Domino 30 **(2083.153)**.

In the **Roland** II configuration a tracking radar is used in place of the periscope sight, otherwise the principle of operation is the same. Since one of the features claimed for the system is that rapid transition from radar to optical or optical to radar tracking is possible – even with the missile in mid-flight – it is reasonable to assume that the radar and optical axes are maintained in alignment.

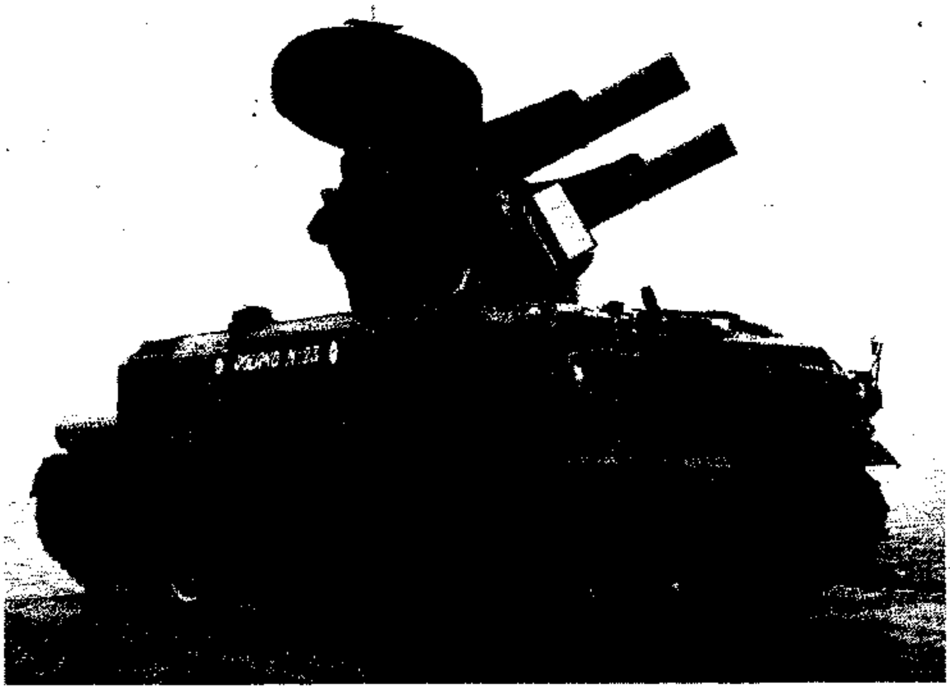
The tracking radar is a monopulse type with a magnetron transmitting valve and Doppler receiver circuits to reduce clutter returns. It is said to have a parabolic Cassegrain aerial and to use circular polarisation. The aerial is gyro-stabilised in bearing and elevation – necessary because the radar is required to have a high resolving power and the weapon system is intended to be used, if necessary, on the move.

The radar deals simultaneously with the target and the missile, missile position in relation to the radar beam being established by continuous-wave transmission from the missile beacon.

Command signals are passed to the missile in flight by a radio link and the commands are interpreted as steering movements of vanes in the efflux from the sustainer motor. This command link has been reported to be a microwave link, but this report is unconfirmed.

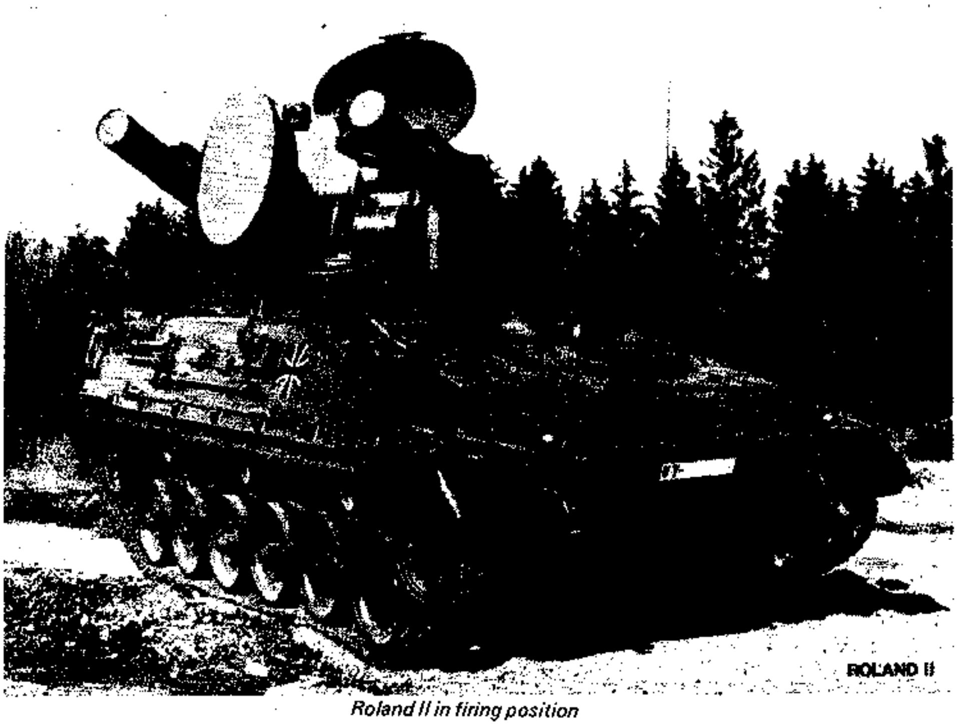
DEVELOPMENT:

Development of Roland has been one of the joint Franco-German operations carried out by Messerschmitt-Bölkow-Blohm and Aérospatiale. The first design study was made in 1964. The French Army was prepared to accept the Roland I configuration when it became available (evaluation in 1971-72) but the German Army decided to wait for Roland II. Other customers are Brazil and possibly the USA who have evaluated Roland



Roland I in firing position

Roland launch



Roland II in firing position

II successfully.

TEST AND TRAINING EQUIPMENT:

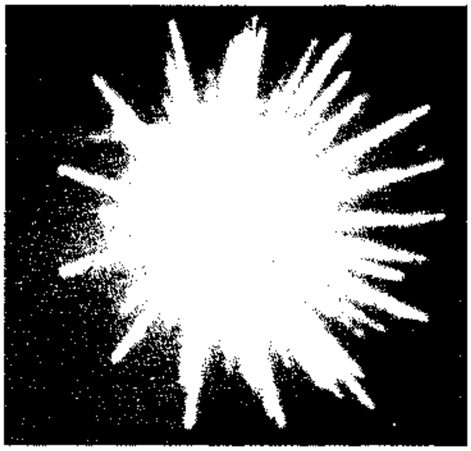
Special test equipment has been developed by Aérospatiale and training equipment by MBB.

MANUFACTURERS:

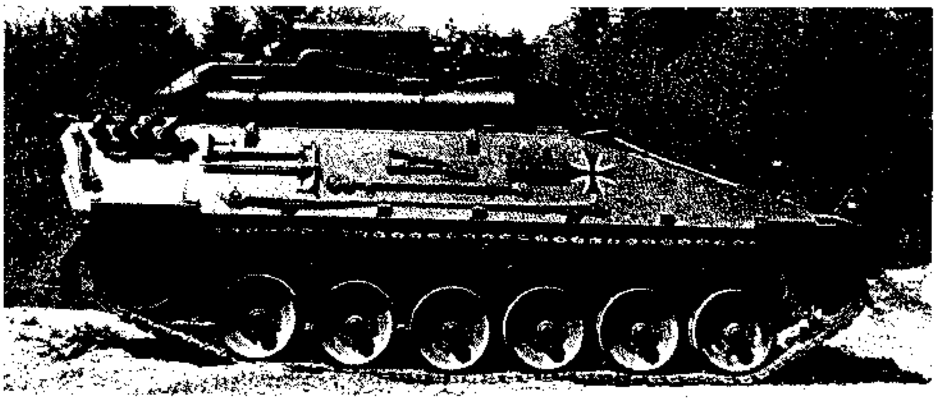
System: Messerschmitt Bölkow-Blohm, GmbH, Munich, Germany, and Aérospatiale, 92-Chatillon, France.

Radars: Thomson-CSF, Paris Siemens, Munich.

Management, sales and responsibility for production: Euromissile, 37 Boulevard de Montmorency, 75016-Paris, France.



Roland warhead explosion



Roland II in travelling position

ITALY

2235.131
INDIGO MOBILE ANTI-AIRCRAFT WEAPON SYSTEM

DESCRIPTION:

Indigo is a short-range surface-to-air land-based weapon system. It has undergone an extensive series of successful trials at the Italian firing range in Sardinia and is now fully operational with the Italian Army in a towed version.

This towed version comprises one or more Indigo trailer launchers and associated trailer power units together with a modified Superfledermaus fire control system (**2291.151**) and LPD/20 pulse doppler search radar (**1529.153**), both of which are made by Contraves. The modification to the Superfledermaus consists mainly of the addition of missile engagement and guidance computers, a missile control panel, a command transmitter and an infra-red tracker.

A self-propelled version is being developed. This will have an Officine Galileo fire control system and Thomson-CSF Eldorado/Mirador radars (**2082/2117.153**). Two tracked vehicles will be used, one carrying the missile launcher and the other the radars and fire control system.

Indigo is intended to respond quickly to an attack. Standard time from target detection alarm to launch sequence initiation is 6 seconds and to motor burn-out (speed 850 m/sec) is 10.5 sec.

Targets can be engaged either with single missiles or with two-missile salvoes. In more than 80 development trial firings with the Superfledermaus system, a single-shot kill probability of 50% was established.

CHARACTERISTICS:

Type: Land-mobile surface-to-air tactical guided missile

Guidance Principle: Beam riding/radio command with standby optical and IR tracking/radio command

Guidance Method: By control of movable cruciform control surfaces at centre of missile. Stabilisation by cruciform tail fins

Propulsion: Solid-propellant rocket motor, 3,800 kg st for 2.5 sec

Warhead: High-explosive (21 kg) fragmentation type with impact and infra-red proximity fuses

Missile Length: 3.32 metres

Missile Diameter: Body: 0.195 metres, Span: 0.86 metres

Launch Weight: approx 121 kg

Speed: Approx Mach 2.5 at burn-out

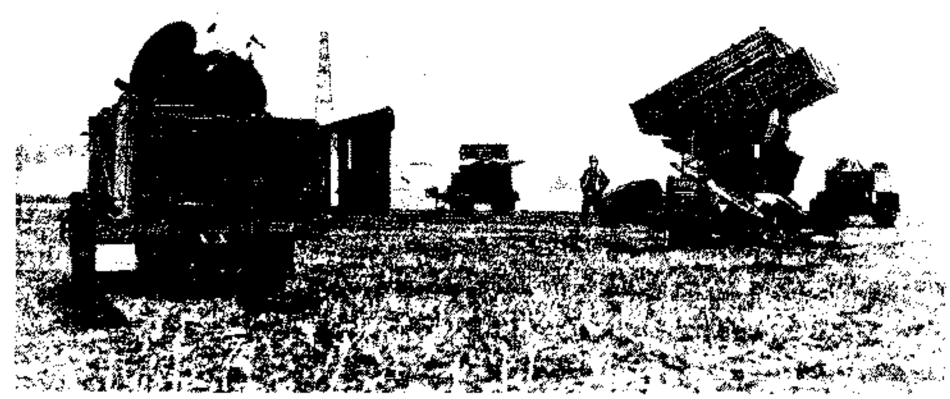
Range: Approx 10 km slant range

Ceiling: Approx 5,000 metres

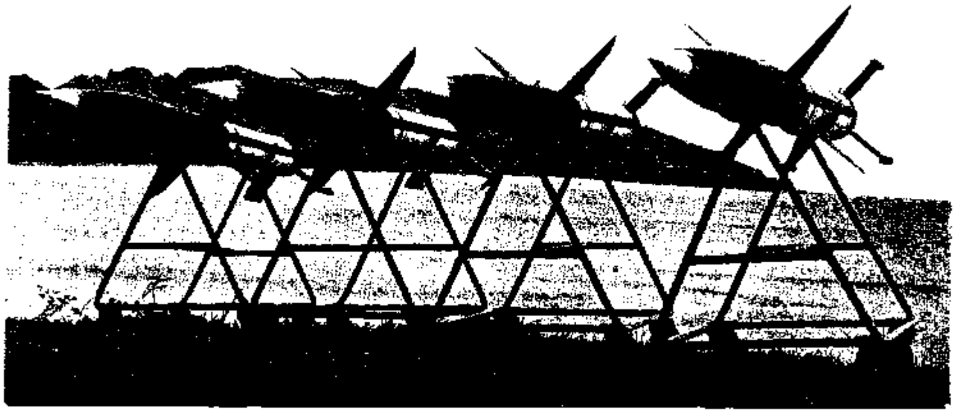
Reaction Time: 6 seconds

OPERATION

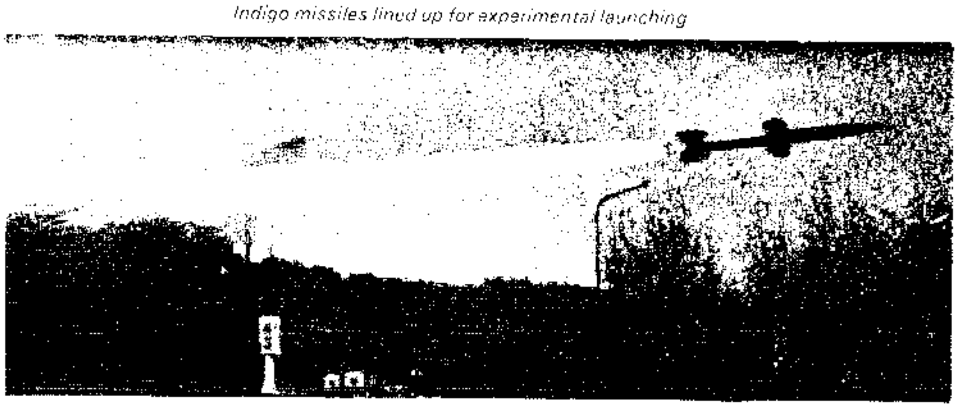
Operation of the missile is similar in principle to that of the Sistel Sea Killer Mk 1 and 2 missiles described elsewhere in this section (**2240.221** and **2253.221**). Primarily intended as a beam-riding system, the missile can also be controlled over the radio command guidance link with optical and infra-red tracking if the beam-riding function is rendered inoperative by jamming or



Indigo weapon system deployment



Indigo missiles lined up for experimental launching



Indigo missile in flight

otherwise. Unlike the Sea Killers, however, there is no radio altimeter in the system.

DEVELOPMENT:
Development of the system was initiated by Contraves Italiana SpA in 1962 and the first prototype was completed in 1963. In 1969 the project was taken over by Sistel SpA.

STATUS:
Towed System – operational.
SP System – in development.

MANUFACTURERS:
The missile is manufactured by Sistel SpA, Via Tiburtina 1210, 00131 Rome.
Test and training equipment is manufactured by Sistel and by Contraves Italiana SpA respectively.
Fire control system by Contraves Italiana SpA, (towed system) or Officine Galileo, Italy (SP system).
Acquisition radars by Contraves Italiana (towed system) or Thomson-CSF, France (SP system).
Proximity fuse by Hawker Siddeley Dynamics, England.
Launcher (both systems) by DEA, Italy.

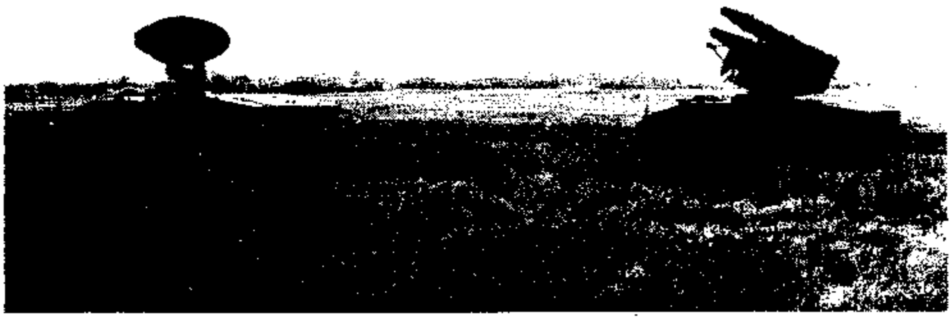
CACTUS

Cactus is the name given to the version of the French Crotale land-mobile surface-to-air guided weapon system which is in service with the South African Air Force.

Crotale is described elsewhere in this section (**2074.131**) and indeed it was primarily for South Africa that the development was originally started. Apart from the change of name, no details of differences between Cactus and Crotale have been released; but comments from usually well-informed sources suggest that it is "a version" of Crotale that is being supplied to South Africa. The Crotale system has undergone some changes in the course of development, and it may well be that the system in service in South Africa is rather different from that which has been supplied elsewhere.

It is interesting to note that the Cactus units in South Africa are linked directly to the early warning radar network which covers the North-East and North-West approaches to the Republic and which has its headquarters at Devon in the Eastern Transvaal. A Mirage interceptor squadron is also linked to the network.



Units of the Crotale / Cactus system

2406.131
BLOODHOUND Mk 2 SURFACE-TO-AIR WEAPON SYSTEM

DESCRIPTION:

Bloodhound Mk 2 is a second-generation mobile anti-aircraft guided weapon sub-system suitable for incorporation in a comprehensive air defence system. The basic unit – a missile section – typically comprises four guided missiles and their launchers, a target illuminating radar (TIR) and a launch control post (LCP). The guidance principle is semi-active homing – the missile detecting and homing on the radiation reflected by the target when illuminated by the TIR.

Basic input required by the missile section is target location information from a surveillance radar which may be directly associated with the Bloodhound sub-system or may be part of the central equipment of a larger complex. This information is supplied to the TIR, which then searches for, acquires and automatically tracks and illuminates the target. Simultaneously, it interrogates the target for positive identification and transmits the appropriate information to the LCP.

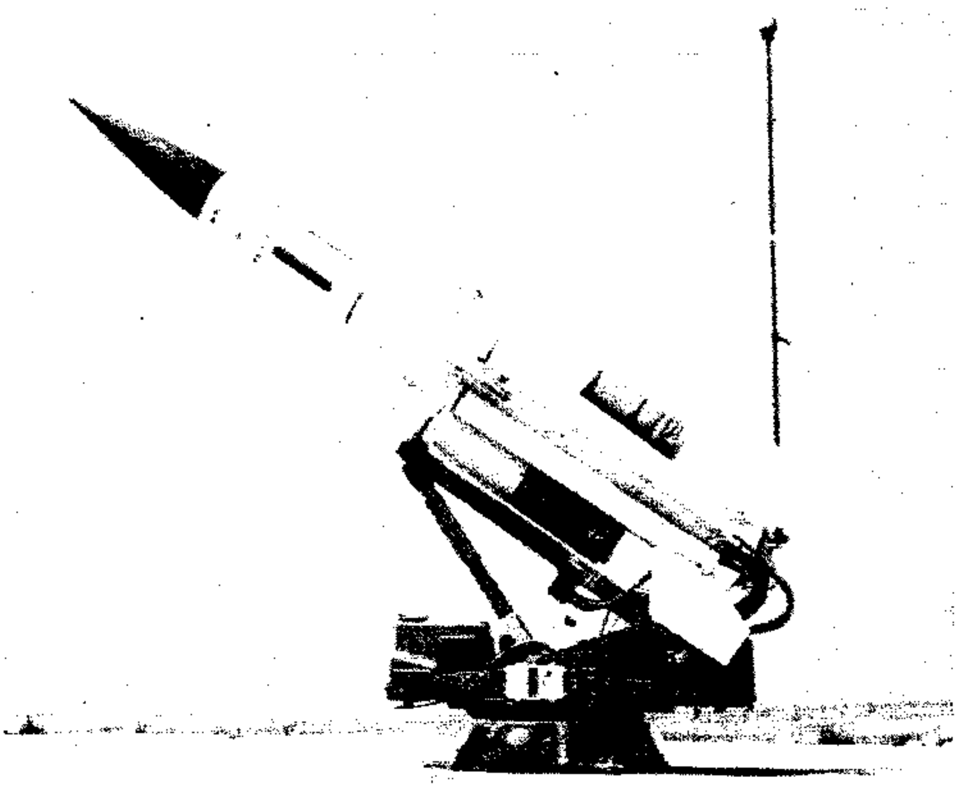
At the LCP, which is the control centre of the missile section, sits the Engagement Controller assisted by a Technical Supervisor. A high-capacity computer in the LCP processes the output data from the TIR to determine the optimum conditions for target engagement. This computer also performs routine tasks concerned with the state of readiness of the system; both the Engagement Controller and the Technical Supervisor are provided with displays and communications equipment to enable the former to take rapid operational decisions and the latter to maintain maximum equipment serviceability.

In the mobile role for which it was first designed, the Bloodhound missile section is normally equipped with the Firelight TIR (**2413.153**) which is readily mobile and air-transportable. The whole equipment is contained in a single cabin and the aerials are mounted on a retractable pedestal on the roof. For static operations – or where system mobility is not a prime consideration – there is an alternative TIR, the Scorpion (**2428.153**), which is a larger radar giving a longer range. It can be broken down into transportable units but cannot be brought into or taken out of operation as quickly as the Firelight. Both radars are X-band CW Doppler equipments having good performance in the presence of natural or ECM interference.

CHARACTERISTICS:

Type: Surface-to-air land-based GW system. Land-mobile. Air-transportable

Guidance Principle: Semi-active homing. Receiver in missile nose detects and follows radiation reflected by target when illuminated by TIR



Bloodhound deployed at Paramali, Cyprus (RAF Photograph)

Guidance Method: Twist-and-steer by pivoting wings

Propulsion: Ramjet with solid-propellant boosters

Warhead: High-explosive, with proximity fuse

Launch Control: From LCP by computer using data from TIR

Radar: Choice of two TIR's – Firelight or Scorpion

Range: Better than 80 km

DEVELOPMENT HISTORY:

Bloodhound Mk 2 is the successor to Bloodhound Mk 1 which first went into service with the RAF in 1958; development having been started by the Bristol Aeroplane Co Ltd and Ferranti Ltd in 1949. The first design study for the Mk2 version was started in 1958; the new version went into service with the RAF in 1964. In the same year the equipment also went into service with the defence forces of Sweden and Switzerland. The system has also been exported in substantial numbers to Australia and late in 1969 BAC were awarded a £10 million contract from the Singapore Government for the refurbishing and maintenance of the Bloodhound system previously operated by the RAF in that area.

Bloodhound-equipped RAF units are currently deployed as part of the NATO air defence of Western Europe.

MANUFACTURERS:

The following manufacturers are known to have been associated with the system.

Overall system, missile airframe etc. (consortium leader): British Aircraft Corporation (Guided Weapons Division), Stevenage, Herts.

Overall electronic system, missile homing system, LCP Computer etc., Firelight TIR: Ferranti Ltd., Edinburgh (TIR) and Wythenshawe (remainder).

Ramjet propulsion system: Rolls-Royce Ltd.

Missile fuse: EMI Ltd.

Scorpion TIR: GEC Electronics Ltd.

TEST AND TRAINING EQUIPMENT:

Engagement controller's simulator: Ferranti Ltd., Wythenshawe.

Homing head test equipment: Ferranti Ltd., Wythenshawe.

Fuse test equipment: EMI Ltd.

Ramjet propulsion system test equipment: Rolls Royce Ltd.

2424.131
RAPIER MOBILE LOW-LEVEL ANTI-AIRCRAFT MISSILE SYSTEM

DESCRIPTION:

Rapier is a lightweight highly-mobile surface-to-air guided weapon system in which a supersonic, direct-hitting missile is automatically, commanded to follow an optically established sightline to the target.

Main operational units of the system are a Fire Unit, an optical Tracker and a Power Unit. These three units can be disposed in any convenient manner, according to terrain, interconnection being by cable. Once the Fire Unit has been loaded with its four missiles (a two-man job) it can be left unattended and the system operated by one man at the Tracker until the missiles have all been fired. No cranes or mechanical handling equipment are required.

In addition to the missile launch mechanism, the Firing Unit contains a search and acquisition radar (**2425.153**) which works in conjunction with an IFF interrogator-responser, a microwave command transmitter and a computer which serves all parts of the system. When the surveillance radar detects a target the IFF automatically interrogates it to determine whether it is friendly or hostile. If the target is friendly all data on it is cancelled and the radar continues its search; if it is hostile the Tracker operator is alerted, the radar data is used to direct the Tracker towards the target and the operator will see it in his optical sight.

After acquiring the target optically the operator takes over from the radar and tracks it using a joystick control – thus generating an output from the tracker that is fed to the fire unit computer. When the operator considers he is tracking smoothly and after receiving a signal from the computer that the target is engageable the operator fires a missile – the launcher having been automatically aligned so that the missile will fly on the line of sight to the target.

While the missile flies towards the target the operator continues tracking. A television camera in the Tracker collimated to the tracking telescope detects flares mounted in the missile tail and measures any deviation from the sightline. These measurements are then fed to the fire unit computer which then causes the command transmitter to transmit correction signals to the missile.

Rapier is intended primarily for defence against fast (Mach 1 +) manoeuvring low-flying targets. It has the fast reaction time necessary for the successful engagement of such targets which may appear suddenly, over terrain screening, at short range. It can also, however, be used successfully against aircraft flying at heights of some thousands of metres

As already noted, Rapier is a direct-hitting system and it has demonstrated its capability in this respect in repeated trials. For this reason it is fitted with an impact fuse. It has been reported, however, that the Norden Division of United Aircraft (who have been collaborating with BAC in US Rapier trials) is developing a proximity fuse for the missile. It has also been reported that they, in conjunction with BAC and the Royal Radar Establishment have set up a mathematical model to explore the effectiveness of Rapier against manoeuvring targets.

In normal operational use the Fire Unit is towed by a long-wheelbase Land Rover which also carries the optical tracker and four missiles in sealed containers; a second Land Rover tows a missile re-supply trailer which carries more additional missiles in identical sealed containers. For continuous operation the normal detachment strength is five men: but three can deploy and man the system and, as already noted, only one man at a time is needed to operate it after loading. A complete system can thus be transported in a Chinook helicopter. Since the system components are small, however, they can be mounted in various other ways – eg on tracked vehicles – to suit special operational requirements.

One such special mounting, illustrated here by an artist's impression is on a general-purpose FMC M-548 tracked vehicle. The basic weapon system, pallet-mounted for convenience of fitment, can be carried on a single vehicle: for the system with blindfire radar (see below) a second vehicle is required. Trials of the tracked system are scheduled for late 1974.

Characteristics: (System with optical tracking)

Type: Surface-to-air land-or vehicle-based GW system
Land-mobile. Air-transportable

Guidance Principle: Command to line-of-sight

Guidance Method: Optical target tracking. Electro-optical missile tracking. Computer calculates course corrections for transmission over command link. Hot gas servos actuate missile fins

Propulsion: Two-stage solid-propellant motor

Warhead: High-explosive with crush fuse

Launch Control: By operator when cleared to fire by computer

Tactical Control: In primary design role as fast-reaction system, none. May be integrated with larger systems

Launch Weight: Not released. Probably about 65 kg

Speed: Not released. Evidently high supersonic

Range: Not released. Ceiling believed 5,000 m

Development History and Prospect:

Developed to satisfy a British Defence Ministry requirement for a low-cost system to combat low-level aircraft attacks, Rapier was the subject of a design study in 1963. It is currently in production, having been ordered by the British Army, the RAF and the Imperial Iranian defence forces. Several more overseas orders are pending and the system was fully evaluated by the US Army in 1972.

Blindfire Development:

The basic Rapier system was designed to combat the daylight/good visibility low-level threat posed by the very large numbers of ground attack aircraft and helicopters which are currently operational. The number of aircraft that can attack at low level by night or in conditions of low visibility is very much smaller, but extension of the system capability to combat this threat was considered necessary as a second priority.

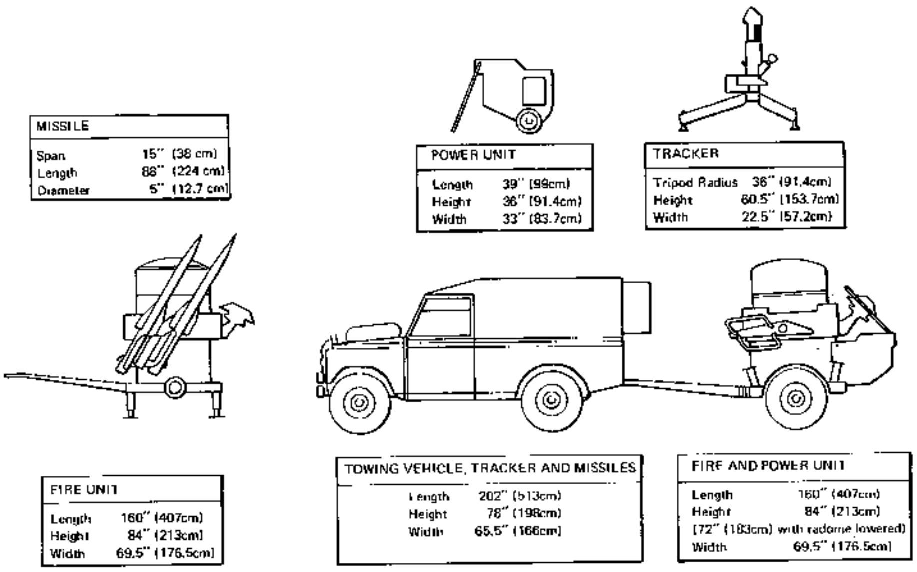
To provide this added capability, BAC have developed, in conjunction with Marconi Space and Defence Systems, an add-on radar **(2439,153)** which provides guidance when optical tracking is impossible.

This "Blindfire Attachment" as the new radar is called, is mounted on the same type of trailer as is used for the Fire Unit. No other details of its construction or performance have been released for publication but a mock-up of the radar was exhibited at Farnborough in 1970 and what appeared to be a fully-engineered model was on show there in 1972 – but with the aerial feed masked as it is in the accompanying illustration.

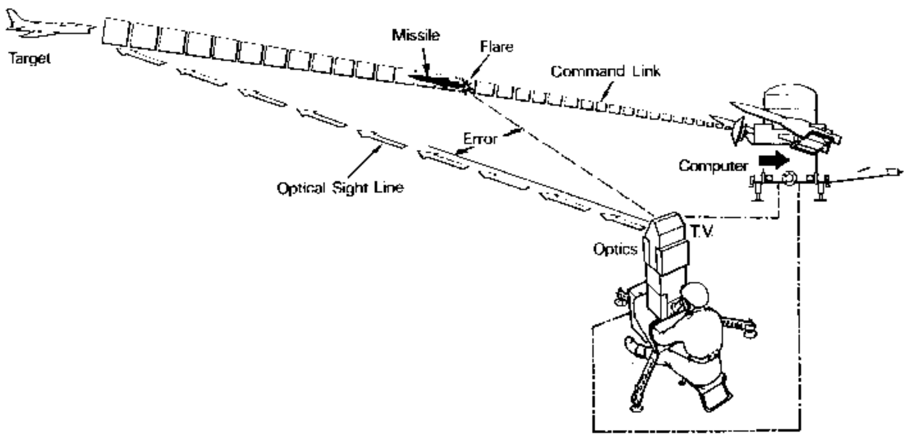
Firing trials of the "Blindfire" system have been conducted, and at the very first attempt the target – a Meteor drone flying at Mach 0.6 at a height of 600 metres – was destroyed by a direct hit. The manufacturers believe that this degree of success in combining a direct-hitting missile with radar tracking is unequalled elsewhere

In daylight conditions, the addition of the "Blindfire" radar to the system gives the operator the option of optical or radar engagement – an

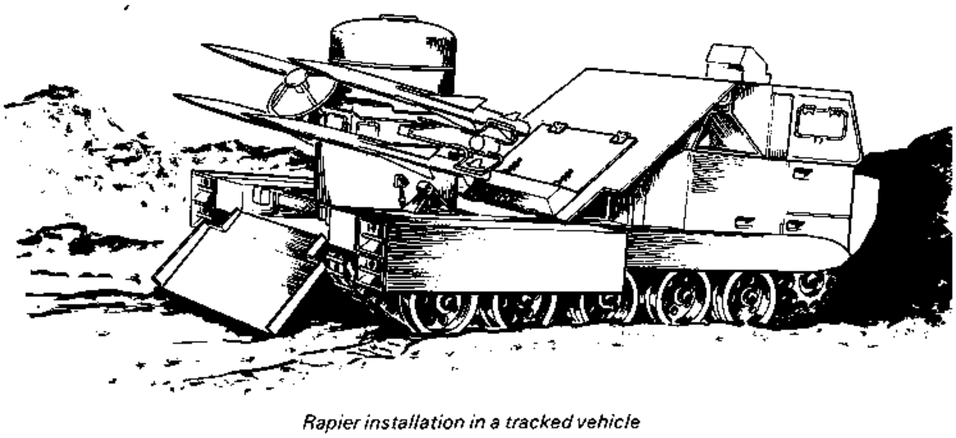
Fire Unit of Rapier low-level anti-aircraft weapon system being readied for action



Rapier dimensions



Rapier guidance system



Rapier installation in a tracked vehicle option which need not be exercised until after the acquisition radar has indicated the presence of a target and, through a remote control link, has enabled the tracker to acquire the target.

A UK production order for the blindfire radar has been placed and Iran has purchased some of these radars for its Rapier systems.

SIMPLIFIED FIRE UNIT

For certain special applications, BAC has proposed and demonstrated a less elaborate Fire Unit from which the search and acquisition radar and the relevant sections of the computer have been removed. Such a unit could provide an inexpensive way of increasing the fire power of a battery between reloadings, since the radar in one complete fire unit could seek out targets for other, incomplete, fire units. Alternatively the simple fire unit could be used as a visual system independent of radar using a simple printing sight to programme the tracker with target angular coordinates plus an estimate of range.

MANUFACTURERS:

The following manufacturers are known to have been associated with the system.

Weapon System: British Aircraft Corporation Ltd, (Guided Weapons Division), Stevenage.

Safety and Arming System: Marconi Space and Defence Systems Ltd.

Primary Radar: Decca Radar Ltd.

Secondary Radar (IFF): Cossor Electronics Ltd.

Servo-Optical Tracking System: Barr & Stroud Ltd.

Command Link: Decca Radar Ltd.

"Blindfire" Radar Attachment: Marconi Space and Defence Systems Ltd.

Missile Rocket Motor: Imperial Metal Industries Ltd.

TRAINING AND MAINTENANCE:

BAC make a special simulator for operator training. They also supply a range of specially equipped repair vehicles for maintaining the system. One of these, the Forward Repair Test Vehicle, is a Land-Rover equipped with automatic test equipment suitable for all first line testing. Two larger vehicles are available for second line work – one for the electrical and electronic equipment and the other for the optics and hydraulics.

2460.131
THUNDERBIRD 2 SURFACE-TO-AIR MISSILE SYSTEM

DESCRIPTION:

Thunderbird 2 is a versatile mobile medium-to-high level anti-aircraft guided weapon system capable either of being operated independently as a self-contained system or of being integrated into a larger air defence complex. The system description that follows relates primarily to its use as an autonomous firing unit, but some of the larger configurations of which it forms a part are described elsewhere in this section.

Fully land-mobile – including cross-country driving and rail transport in standard wagons – and air transportable Thunderbird 2 is a rugged system designed for use in any climate from unprepared sites; it is claimed that targets can be engaged in 2¼ hours from arrival at such a site.

When organized for autonomous operation the basic system unit is the missile battery. This is subdivided into missile firing units each of which has a group of missile launchers and a Launch Control Post (LCP) and a Target Illuminating Radar (TIR). Controlling the operations of these sections through the LCP's is the Battery Command Post (BCP) with which is associated, in the minimal configuration, a Tactical Control Radar (TCR) and a Height-Finding Radar (HFR). If the weapon system is organised on a regimental basis or as a part of a larger defence complex, a central group of radars – that may include long-range surveillance, gap-filling and height-finding radars – may serve several BCP's but the basic principle of operation remains the same.

Radar data, from whatever source, on targets in the operational area is supplied to the BCP as also is missile state-of-readiness information from the LCPs. Display and computer facilities at the BCP permit the presentation of all relevant tactical information to the officer in charge and for the storage of target tracks. Targets are allocated to the firing units from the BCP and the target data is passed by digital link in a form that enables the TIR of each firing unit to search for and acquire its selected target.

When the target has been acquired the TIR automatically tracks it, transferring data to the LCP, where facilities are provided for carrying out an automatic pre-launch preparation sequence and where there is also a comprehensive communication network linking the LCP to the BCP, TIR and launcher sites.

After missile launch the TIR continues to track the target, and the radiation reflected from the target is used by the semi-active equipment in the nose of the missile to guide it to a close approach. The missile carries a high-explosive warhead which is detonated by a proximity fuse.

Standard equipment for mobile Thunderbird 2 systems is the Firelight TIR (**2413.153**). This is a CW X-band Doppler radar; the advantage of using CW being its good performance in the presence of ground clutter or ECM interference.

DEVELOPMENT HISTORY:

Thunderbird 2 is the successor to Thunderbird 1 which first went into service with the British Army in 1960. The design study for the second-generation equipment was started in 1956 and the new equipment went into British Army Service in 1965. Thunderbird 1 was supplied to the Defence Forces of Saudi-Arabia in 1966.

CHARACTERISTICS:

Type: Surface-to-air land-based GW system. Land-mobile. Air-transportable
Guidance Principle: Semi-active radar homing
Guidance Method: By pivoting tail surfaces
Propulsion: Solid-propellant sustainer with four solid-propellant boosters
Warhead: High-explosive, with proximity fuse
Tactical Control: From BCP by digital link to LCP
Launch Control: From LCP to launcher sites using TIR data
Missile Length: 6.40 m
Body Diameter: 0.54 m
Span: 1.63 m
Range: Not released. Probably in excess of 75 km

MANUFACTURERS:

The following manufacturers are known to have been associated with the system.

Main System Contractor: British Aircraft Corporation (Guided Weapons Division)

Battery Command Post: Marconi Radar Systems Ltd., Cossor Electronics Ltd., Ferranti Ltd.

Tactical Control Radars: Marconi Radar Systems Ltd., Cossor Electronics Ltd.

Target Illuminating Radar: Ferranti Ltd. (Edinburgh)

Digital Data Links: Ferranti Ltd., (Bracknell)

Fuse: EMI Ltd.

Test & Training Equipment:

Sensitivity Test Set: BAC

Missile Test Set: BAC

Firing Troop Trainer: Sperry Gyroscope Co Ltd.

Thunderbird 2 missile

2465.131
TIGERCAT CLOSE RANGE AIR DEFENCE SYSTEM

DESCRIPTION:

Tigercat is a land-based version of Short Bros.' highly successful SEACAT and is a ground-to-air guided missile system for low-level close-range air defence.

In the design of both Seacat and Tigercat the policy has been to create a simple guided weapon capable of instant readiness. With any kind of radar warning system there is always the possibility of aircraft approach without detection to a range that permits little time for firing sequences. With Tigercat no prefiring sequences are required on the launcher; and auxiliary power services within the missile are activated at launch. The system is thus capable of engaging and destroying at close range even rapidly manoeuvring targets.

SYSTEM DESCRIPTION:

Tigercat is compact and mobile and has cross-country capability. The basic fire-unit comprises a director trailer, a launcher trailer, and two towing vehicles. These vehicles carry the fire-unit crew of five men, generating equipment, missiles and miscellaneous items. Power supplies are obtained from the generator or from public supply. The launcher trailer consists of a two-wheel chassis integral with a three-missile launcher. For operational use the chassis is supported and levelled on three jacks and the road wheels removed. The Director trailer also has an integral two-wheel chassis which is levelled and supported on three jacks. The Director incorporates an adjustable seat for the aimer and an auxiliary rotating structure on which is pivoted the sight arm carrying the aimer's binocular sight, flight controller and missile firing trigger. The control officer's console is a fixed box structure built on to the rear end of the trailer chassis. A door at the rear opens upward to provide access to the equipment within the console and together with a nylon windbreak forms a shelter for the launch control N.C.O.

The principle of operation is that after a target is acquired by the aimer the missile is launched into the aimer's field of view. The aimer then directs the missile to fly along the line of sight to the target by manipulating a thumb-operated flight controller which applies up, down, left and right commands to the missile by means of a radio link. Flares at the rear of the missile help the aimer to keep it in sight. As with Seacat the system is also suitable for operation using either radar or television guidance.

The Marconi ST850 radar has been designed to function as an integral part of Tigercat and provide

Tigercat launch

both dark-fire and blind-fire capabilities. It is an X-band target tracking equipment with good range performances. The magnetron pulse-transmitter, with a typical peak power output of 180 kW is tunable to counter ECM and a low selection of operating frequencies to prevent mutual interference when a number of similar systems are operating in the same area. Digital MTI is used to minimise ground returns and allow tracking of low flying aircraft. The sequence of radar operations is carried out automatically under control of a master programming unit.

The television camera is aligned to the radar boresight and provides optical information on the target being tracked by the radar. The system comprises both a conventional camera and display and a data processing system which permits automatic gathering of the Tigercat missile to the target sight line.

The ST850 is contained in a mobile air-conditioned cabin with the radar director on its roof. The system is simple to use, flexible in operation and can be speedily deployed.

When the ST850 system is added the aimer sits at the ST850 control console in the cabin instead of in the Tigercat visual director, and is presented with optical information from the television system in a manner similar to that presented on the binocular sight, and he has a similar type of flight controller. The duties of target tracking are taken over by the radar which acquires and tracks automatically.

CHARACTERISTICS:

Type: Surface-to-air close-range tactical guided missile

Guidance Principle: Command link with optical or radar/TV tracking

Guidance Method: Aerodynamic by movable wings

Propulsion: Two-stage solid-propellant motor

Warhead: High explosive

Missile Length: 1.48 metres

Missile Diameter: 19 cm

Launch Weight: 63 kg

DEVELOPMENT HISTORY:

The manufacturers were awarded a British Government contract for Seacat in 1958 but the development of Tigercat was a company initiative. The weapon system is now in production, is in service with the RAF Regiment and the Imperial Iranian Air Force, and is in service with or has been ordered by several other overseas countries including Argentina, Jordan and Qatar.

MANUFACTURERS

Short Brothers & Harland Ltd, Belfast, Northern Ireland make the complete system including special test and training equipment. Other manufacturers known to be associated with the system are IMI Ltd who make the rocket motor and EMI Ltd who make the fuse.

CHAPARRAL SURFACE-TO-AIR WEAPON SYSTEM

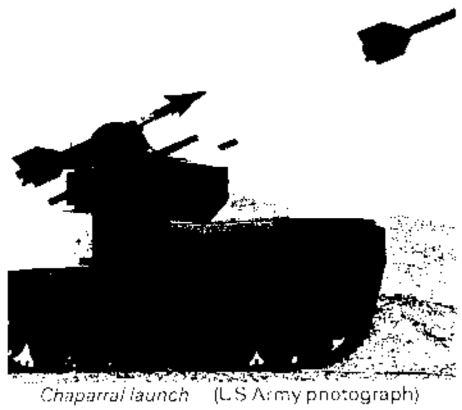
DESCRIPTION

Chaparral is a ground-to-air infra-red heat-seeking missile system which has been developed to meet U.S. Army requirements for a low-altitude air defence weapon.

The system consists of a launch and control assembly, vehicle and missile. The missiles are carried on and fired from a turret mounting four launch rails. Additional missiles are stored for ready access in the pallet. The gunner in the turret mount aims the missile at the target using an optical sight. Once locked-on to the target and fired, the missile guides itself to the target's heat source automatically. The Chaparral missile is a US Navy developed Sidewinder 1C, which has been modified for ground to air rather than air to air launch as now used by the Navy. The Navy supplies missiles for Army use.

The launch and control assembly is a self-sustaining unit, capable of operation independent of the carrier vehicle in a ground emplacement mode. For missions requiring full-tracked mobility the fire unit is mounted on an M-730, self-propelled tracked vehicle. It is amphibious when a "swim kit" is used, will carry a five-man crew, and can travel up to 64 kilometres per hour on the road.

One of the operational configurations is the association of Chaparral with the Vulcan air defence gun system (**2850.131**), the latter being a six-barrelled 20 mm Gatling gun adapted for ground use and mounted on a modified M-113 personnel carrier. Forward area alert radar (FAAR **1526.153**) can be deployed with Chaparral/Vulcan to provide early warning and IFF identification



Chaparral launch (US Army photograph)

within the detection area.

CHARACTERISTICS:

US Army Designation: M-48
Type: Land-mobile surface-to-air guided missile system
Guidance: Infra-red homing after optical aiming
Missile Designation: MIM-72A
Propulsion: Solid-propellant rocket motor
Warhead: High-explosive
Missile Length: 2.91 metres
Missile Diameter: 13 cm
Span: 64 cm
Launch Weight: Approx 84 kg
Speed: Supersonic

DEVELOPMENT:

Development was started in 1965 by the Aeronutronic Division of Philco-Ford on a contract from the U.S. Army Missile Command. Trial firings began in July 1965 from prototype fire units: an initial tooling and production contract followed in April 1966 and by early 1968 a total of 154 systems were reported to be on order.

It is understood that the US Army have plans for the further development of Chaparral to improve daytime target acquisition and tracking and night operations. The proposal is to refit the Chaparral/Vulcan combination with an integrated optical subsystem comprising a laser range finder and a forward-looking infra-red sensor, both being aligned on a common tracking mount. In the FY 1975 Defence Budget proposals provision was made for retrospective modifications to increase the reliability and maintainability of the missile fuse, improve warhead lethality and "provide a forward aspect engagement capability" – the last item presumably relating to the IR sensor.

STATUS:

Operational. Production of current version was completed in the Autumn of 1971. Modification programme noted above.

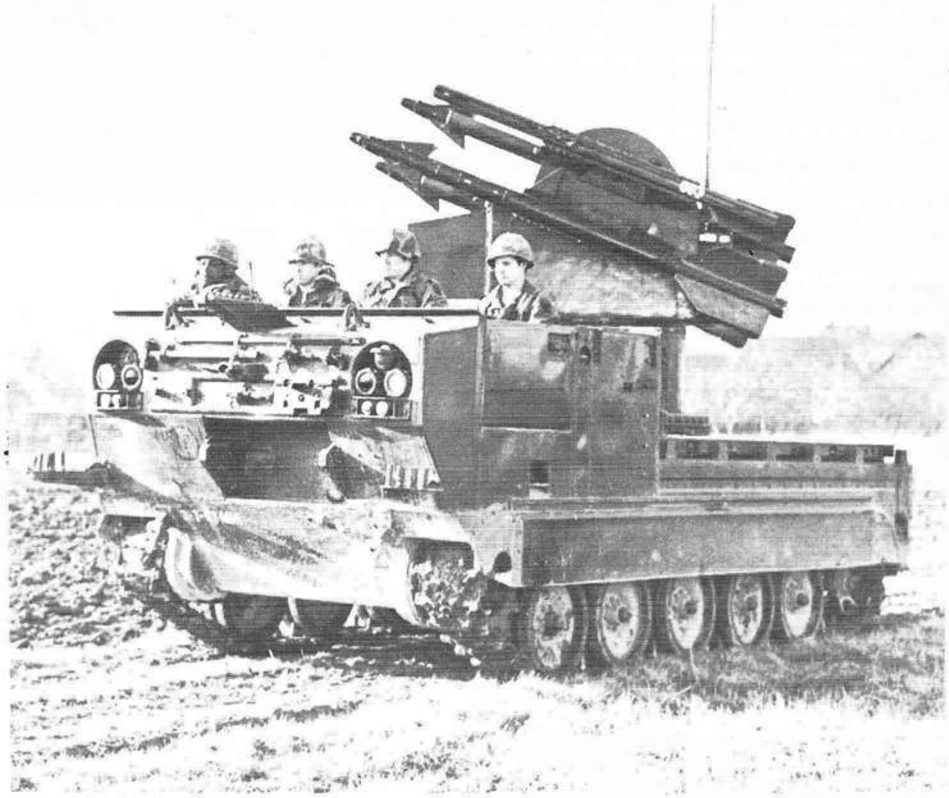
As noted above, further development of Chaparral is a possibility, but the US Army is considering, in parallel with this possibility, that of purchasing an existing system as a Chaparral replacement. To this end the Army has been evaluating Crotale (**2074.131**), Rapier (**2424.131**) and Roland II (**2218.131**).

MANUFACTURERS:

Complete System: Aeronutronic Division, Philco-Ford Corporation, Newport Beach, California 92663.

Missile Guidance and Control: Raytheon Company Missile Systems Division, Bedford, Massachusetts 01730.

Vehicle: FMC Corporation, San Jose, California.



Chaparral surface-to-air weapon system in its mobile role

2640.131
HAWK SURFACE-TO-AIR WEAPON SYSTEM

DESCRIPTION:

HAWK (homing-all-the-way-killer) is a surface-to-air missile designed primarily to engage low-level supersonic targets but capable of intercepting such targets at altitudes ranging from 30 to 11,000 metres.

The missile also has anti-missile capability – indeed the first known kill of one supersonic missile by another was achieved in January 1960 when a Hawk destroyed an Honest John battlefield missile.

SP Hawk launcher

CHARACTERISTICS:

US Army Designation: MIM-23A
Type: Mobile surface-to-air guided weapon system
Guidance: Semi-active homing
Propulsion: Two-stage solid-propellant motor
Warhead: High-explosive, blast fragmentation type
Missile Length: 5.12 metres
Missile Diameter: 35 cm
Span: 1.22 metres
Weight: Approx 580 kg
Speed: Supersonic
Engagement Altitude Limits: From less than 30 metres to more than 11,000 metres

Details of the functions of the units of the complete system are given below. In certain circumstances it may be necessary to bring missiles into action with less support equipment, and some notes on the way in which this can be done will be found later in this entry.

Battery Control Centre

Control of the battery is exercised by five operators in the battery control centre.

A Tactical Control Officer (TCO) makes all decisions to engage targets. He has an assistant to aid in detection, identification, evaluation and coordination with higher commands. The tactical control console gives these operators the necessary target and battery status information and the required controls. A second assistant has the sole mission of detecting low altitude targets from the separate CW acquisition radar display.

Targets selected by the TCO for engagement are assigned to the Fire Control Operators (FCO). Each operator has his own display and control console to perform rapidly the functions of target acquisition, missile launching, and intercept evaluation.

The electronic equipment and operating personnel of the battery control centre are housed in an air-conditioned, lightweight shelter that can be transported by truck, helicopter, or, for short distances, on its own dolly.

PULSE ACQUISITION RADAR:

Volume radar coverage around the battery is provided by the Pulse Acquisition Radar. This is mounted on a pallet which can be separated from the trailer on which it is normally mounted, so that radar and trailer can be separately lifted by helicopter.

CW ACQUISITION RADAR:

This radar provides for the earliest possible detection of low-altitude targets by employing continuous wave techniques. The rotation of its antenna assembly is synchronised with that of the pulse acquisition radar, so that the target data from both radars can be presented on composite displays for ease of correlation.

RANGE-ONLY RADAR:

Operating in a different frequency band from the other acquisition radars, this is a quick-response range-measuring radar that is capable of being slaved in angle to either of the two target illuminators on demand. Target information from this radar is sent to the BCC where it is used by the FCO to generate range and range rate information for the illuminator.

Guidance Group

The guidance group consists of the CW illuminator and the CW semi-active homing missile.

Continuous wave radar provides the clutter discrimination necessary for low altitude operation. The CW illuminator acquires, tracks, and illuminates targets. It searches automatically at the designated target azimuth until acquisition, and then automatically tracks the target as long as required. In addition, the illuminator also supplies a reference signal for the missile.

The missile contains a radar receiver with a tracking seeker antenna and a closed loop autopilot. Information obtained from received energy is used to direct the missile to home to intercept and to detonate the warhead at the closest approach to the target.

ILLUMINATOR:

Primary functions of the illuminator are to illuminate the target and provide a reference signal to the missile. To do this it can search a designated sector for targets, lock onto the reflected energy and track the target in speed and angle. Aiming the launcher and providing target information to the battery control centre are secondary functions. Functionally identical illuminators of two radiated power levels have been developed. With the high power illuminator the range capability of both the missile and the illuminator are significantly increased in addition to providing a basic capability against targets of much smaller radar cross-section.

Launching and Handling Group

The complete missile is received by the firing battery in a single tactical container. It is removed from the container by the tracked loader operating as a crane and placed on the storage and transportation pallet or on the launcher. The fully trainable launcher activates, aims and launches the missile upon a command from the BCC. When a launcher becomes depleted of missiles during a firing engagement, the loader brings ready missiles from the storage area and reloads the launcher, and can do this with sufficient speed to enable a high firing rate to be maintained.

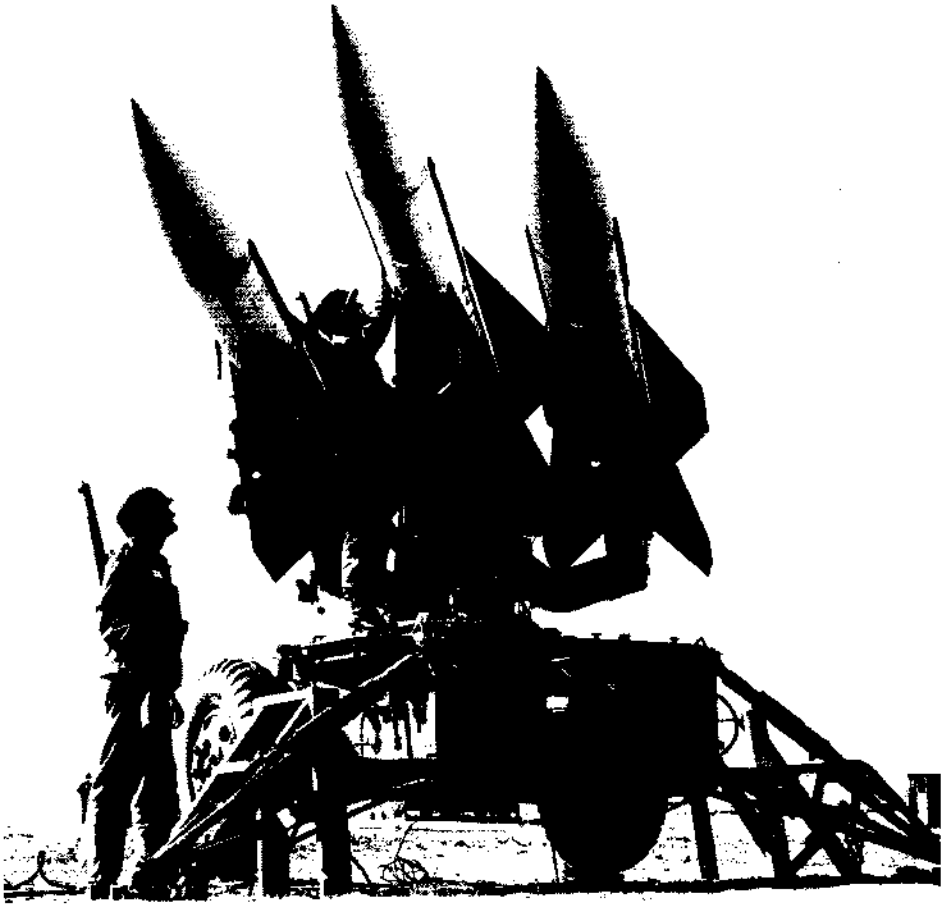
LAUNCHER:

The launcher carries three missiles and is trainable in azimuth and elevation. After illuminator lock, it is slaved to the illuminator in angle to aim the missile at the target. Upon receipt of a fire command from the battery control centre, the launcher selects a ready missile, activates the missile power supplies, enables stabilisation of the missile antenna, and slews to the lead angle commanded by the illuminator. After the lead angle is inserted, the missile rocket motor is ignited and the missile is launched.

Assault Phase

In certain mobile operational circumstances – for example when establishing a beach-head in enemy territory – it may be necessary to bring the missile into action in less time and with less equipment than is necessary to set up the complete battery installation.

To meet this requirement an Assault Fire Command Console has been developed. This is a lightweight fire control unit capable of controlling a firing section, and a CW acquisition radar if available. For minimum equipment deployment, however, the acquisition radar may be omitted and the illuminator programmed to search a designated sector for targets. The minimum equipment configuration, therefore known as an Assault Phase Firing Unit, comprises a single



Hawk missiles loaded on the triple launcher

launcher, an illuminator, a generator, a loader and pallet, the assault fire command console and a supply of missiles. Once the missiles have been loaded onto the launcher the whole of this minimum system can be controlled by one man.

As the tactical situation allows, this minimum unit can be progressively augmented up to full battery strength: alternatively a series of such units can be "leap-frogged" to provide continuous air defence for an advancing army.

SP Hawk

Mobility of the Hawk system has been further increased by the introduction of the SP Hawk, a self-propelled system with the equipment mounted on XM-727 full-tracked vehicles. A self-propelled Hawk platoon comprises three such vehicles each with three ready missiles on a launcher and each towing a piece of ground support equipment.

DEVELOPMENT HISTORY:

Development of the Hawk began in 1954 and the system first became operational in 1959, the programme having been under the technical control of the US Army Missile Command. Engineering of the system was performed at Raytheon's laboratories at Bedford and Wayland, Massachussetts, and at White Sands, New Mexico. US production of the missile and radar-equipment has been principally at Andover and Waltham, Massachusetts.

For European manufacture of the system a five-nation group of companies formed the Société Européene de Téléguidage (SETEL) in 1959. SETEL has acted as prime contractor for the project and coordinated the activities of five individual companies (see below). The system is also manufactured under licence by Mitsubishi in Japan.

Hawk has been extensively deployed by the US forces – both the Army and the Marine Corps – in Europe, Vietnam and other theatres. It has been sold or supplied on grant aid programmes to Israel, Japan, Korea, Saudi Arabia, Spain, Sweden and Taiwan as well as to many NATO countries.

Improved Hawk

This recent development has a new guidance package, a larger warhead and an improved solid propellant. Other improvements include increased ECM protection and the introduction of the 'certified round' procedure whereby missiles are delivered ready to fire without field maintenance or testing. In trials against Firebee drones in the Autumn of 1971, 16 hits were scored out of 17 trials with the improved missile. This was an improvement on the results achieved earlier in the year, and the trials were followed by Standard A approval in December 1971 and full production approval in January 1972. Improved Hawk is currently in production: the first Basic Hawk battalion was converted to Improved Hawk in November 1972 in USAREUR / Seventh Army.

STATUS:

Hawk is expected to remain operational for several years. US Army and Marine Corps units are currently re-equipping with Improved Hawk: Army procurement (90 batteries) is expected to be complete in FY 1977 and USMC procurement (14 batteries) in FY 1976. It is still intended that Hawk should be replaced by SAM-D (**2800.131**) in the 1980s – at which time the Hawk units will probably be transferred to the US Army Reserve and National Guard forces – but in the meantime there is a need for a more mobile and more quickly deployed tactical air defence system than Hawk and this is the rationale of the US SHORADS programme (**2793.131**).

Another programme which until recently had low priority but which is now being re-examined is one referred to as **Hawk 3**. This involves the introduction of a new missile with a different shape and internal arrangement of components. Status of this programme is still experimental, however.

Countries which have Hawk in their military inventories (including these supplied by SETEL) are Belgium, Denmark, France, Israel, Italy, Japan, Netherlands, Saudi Arabia, South Korea, Spain, Sweden, Taiwan and West Germany.

Hawk production by SETEL is complete (but see **2213.231**) but Mitsubishi is expected to continue manufacture for the JGSDF until 1977.

MANUFACTURERS:

Complete System and US Production: Raytheon Company, Lexington, Massachusetts.

Sub Contractors:
Rocket Motors: Aerojet General Corporation, El Monte, California.
Wings and elevons: Northrop Corporation, Beverley Hills, California.
Warheads: Iowa Ordnance Depot.
SETEL Consortium:
Belgium: ACEC
France: CFTH
France: Thomson-CSF
Italy: Finmeccanica
Netherlands: Philips
West Germany: Telefunken
Japanese Manufacture:
Mitsubishi.

2800.131
SAM-D TACTICAL AIR-DEFENCE SYSTEM

Description

SAM-D (Surface-to-Air Missile Development) is the name given to an advanced guided weapon system conceived as a replacement for the Hawk and Nike-Hercules systems in the 1970's. Serious questions as to the missile's cost and desirability raised by Congressional critics led to speculation in 1969 that the project might be cancelled or postponed. However, the US Secretary of the Army announced in the spring of 1970 that an intensive review of the programme had found that SAM-D would provide a better defence with one-third of the manpower and at less than half the annual operating costs of the Hawk and Nike-Hercules systems.

Since then development has continued: in March 1974 the US Defence Secretary said that after an intensive review of the status of the programme it had been decided to emphasise austerity in the programme and ensure adequate testing of the radar and guidance systems before proceeding with engineering development. From this and other speeches made at the time it seems reasonable to infer that the US authorities are confident of the success of the development but are determined to avoid the excessive cost that might result from over-hasty decisions.

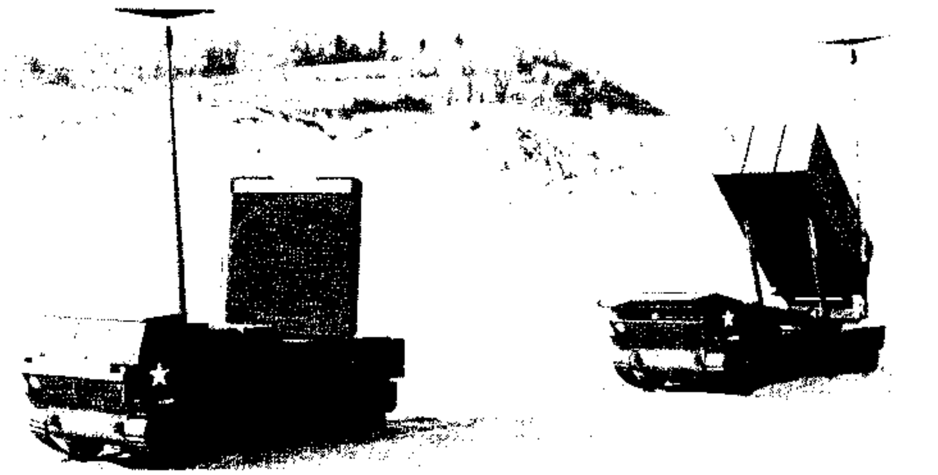
SAM-D can be deployed as a battery to provide circular defensive coverage or as a fire section to provide coverage over a sector. A fire section will consist of one fire control group and one or more (normally two) launcher groups, and may be detached from the major control elements for autonomous operations. A SAM-D battery will normally include four firing sections, and each launcher group will contain six missiles, thus giving each battery a total of 48 missiles. Such a field battery would be mounted on approximately twelve vehicles and would include three main elements: fire control, launchers, battery control and communications groups.

The fire control group will contain the phased array radar, a radar/weapons control computer, communications and prime power equipment mounted on a single tracked or wheeled vehicle. It will also house the operators, controls and displays for the firing section. The radar/weapons control computer will control the phased array radar in its search, acquisition, track and engage functions. It will also assess the threat and determine the best engagement procedure. The phased array radar antenna will have an eight-foot diameter face made up of 5,240 phase shifters. This radar will be capable of performing all the functions for which several radars are needed in some other systems – notably, of course, Hawk (**2640.131**) which can use four radars at a time and Nike Hercules (**2723.131**) which can use five.

The battery control group will coordinate firings within a battery and serve as a communications centre. It will house a computer for handling high data-rates and processes and will coordinate information between radars and pass on fire-control information.

Also mounted on a tracked or wheeled vehicle, the launcher group will consist of six missiles in launching-shipping containers. The missile is cradled within the canister or container supported by teflon-coated launch rails. At launch, the motor blast shatters the rear plastic cover and the missile breaks through the forward plastic cover. The system is capable of firing missiles from their canisters either singly or in close sequence salvoes at selectable azimuths and elevations.

The missile, controlled by four aerodynamic tail fins powered by control actuators, can carry either a high explosive or nuclear warhead. It is segmented into nose, guidance, warhead, motor and control sections.



Models of the units comprising the minimum fire unit of the SAM-D surface-to-air guided missile system – shown here in the operational mode

Minimum fire unit of SAM-D in transit

SAM-D Battery control group model

As a field army weapons system, SAM-D will be designed to destroy FB-111-type aircraft carrying nuclear or non-nuclear weapons and having good low altitude performance and high manoeuvrability. It will also be capable of defeating tactical ballistic missiles, air to surface missiles and submarine-launched cruise missiles. It has also been stated that the system will maintain its effectiveness despite intense electronic jamming.

An Army SAM-D air defence missile is launched successfully during a controlled flight test at White Sands Missile Range, New Mexico

Characteristics

Type: Land-mobile, surface-to-air guided weapon system

Guidance Principle: Command guidance and semi-active homing

Guidance Method: By control of four aerodynamic control surfaces

Propulsion: Single-stage solid propellant rocket motor TX 486

Missile Length: 5.2 metres

Missile Diameter: 40 cm

Warhead: Nuclear or high-explosive

Speed: Supersonic

DEVELOPMENT HISTORY:

SAM-D is the successor to two earlier study programmes managed by the US Army Missile Command's Research and Development Directorate. These studies were concerned with systems known as the Field Army Ballistic Missile Defence System (FABMDS) and the Army Air Defence System for the 1970's (AADS-70s).

In January 1965 the SAM-D requirement was specified and a study was directed towards defence against high-performance aircraft – at all altitudes – and short-range missiles. At the same time two independent organisations went to work on a component verification programme and conducted concept formulation studies.

SAM-D was placed under project management at the US Army Missile Command in August 1965; and shortly thereafter the contract definition process was initiated by the Department of Defence. On the results of this letter contract was awarded to Raytheon in May 1967.

In February 1970 the missile successfully completed its first launch environmental test. The full-scale, flight-weight missile was fired from a non-tactical canister and launcher to prove out the "bazooka" launch technique to be employed with the tactical system.

The US Army planned to begin engineering development in Fiscal Year 1971, but the missile flight test part of advanced development was not completed until April 1971 with the last of ten flight tests and the remainder of the advanced development phase was not completed until March 1972 when engineering development started.

STATUS:

Following the programme review announced by the Defence Secretary (see above) the programme now calls for a system demonstration test comprising sixteen missile firings at difficult targets and extending over a twelve-month period ending in June 1975. At the time of writing the advanced development Fire Control Group has been converted into a demonstration fire section at White Sands Missile Range and tracking and control tests are being carried out in preparation for the system demonstration tests. A cost-effectiveness study is also being conducted with a view to reducing the hardware cost per fire section to a figure comparable with that of Improved Hawk.

Artist's impression of the towed version of SAM-D in action

MANUFACTURERS:

System: Raytheon Company, Bedford, Massachusetts.

Principal Sub-contractors: Martin Marietta Corporation, Orlando, Florida (missile and shipping/launching canister).

Thiokol Chemical Corporation, Huntsville, Alabama (propulsion unit).

2842.131
SHORADS/LOFADS AIR DEFENCE MISSILE SYSTEM

DESCRIPTION:

The two acronyms in the title of this entry appear to be competing with each other to become the agreed description of a single US project. LOFADS (or sometimes LOFAADS) stands for Low Altitude Forward Area (Air) Defence System(s) and SHORADS stands for Short Range Air Defence System(s).

The project relates to the US Army's need for a mobile all-weather anti-aircraft missile system which can be used in the defence of combat units against low-level attacks by high-speed aircraft.

Because the need is seen to be urgent; because no current US development project is aimed specifically at satisfying this need, or likely to be able to satisfy it in the near future; because there are in Europe three developed, tested systems all of which offer facilities which are broadly in line with the US requirement; and because the cost analysts have calculated that it would be cheaper for the US forces to buy one of these systems than to develop a new one, the authorities have taken the unprecedented step of evaluating these three guided missile systems against the US requirement.

The three systems are the French Crotale (**2074.131**), the British Rapier (**2424.131**) and the Franco-German Roland (**2218.131**). If one of these is selected to equip the US forces, the equipment will be manufactured in the USA – all three contestants having designated licensees for such manufacture before the evaluation trials started.

It should be noted that the Chaparral system (**2542.131**) is not yet wholly superseded by the new project. Although Chaperral cannot meet the full all-weather requirements, it still has an important role to play as a clear-weather system – especially when upgraded as recently proposed.

STATUS:

Basic evaluation complete. Decision awaited.

MANUFACTURERS:

None yet designated.

THE UNION OF SOVIET SOCIALIST REPUBLICS

2944.131
SA-1 (GUILD) SURFACE-TO-AIR MISSILE

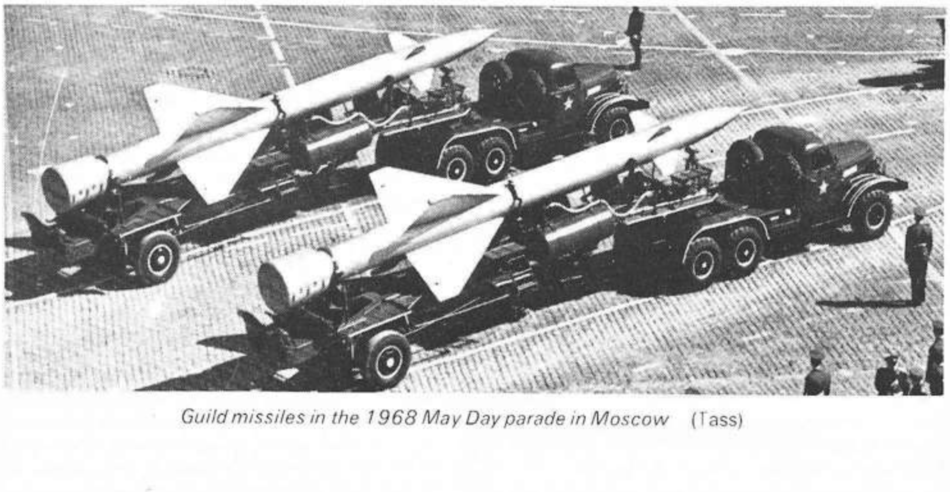
DESCRIPTION:

Guild is the NATO code name for an anti-aircraft guided missile system first shown in Moscow in 1960 and identified by the number SA-1 in the US alphanumeric code.

About 12 metres long and 70 cm in diameter, this missile has no booster stage and therefore probably has a dual-thrust solid-propellant motor. Movable cruciform fore-plane surfaces are another feature of the missile that distinguishes it from Guideline (SA-2, **2942.131**), which has movable tail surfaces but which is otherwise generally of much the same size as Guild.

STATUS:

Said to be operational but not known to have been supplied to any country outside the USSR. Presumably obsolescent.



Guild missiles in the 1968 May Day parade in Moscow (Tass)

2942.131
SA-2 (GUIDELINE) MEDIUM-RANGE SURFACE-TO-AIR MISSILE

DESCRIPTION

Guideline is the NATO code name for a medium range, anti-aircraft guided weapon system, known also by the US alphanumeric code SA-2, which is standard equipment in the Soviet forces and which has been exported in large numbers to many countries outside the Warsaw Pact territory, including Cuba, Egypt, Indonesia, Iraq, North Vietnam and Yugoslavia. Guideline missiles were used against US B-52 bombers during the bombing raids on North Vietnam prior to the peace settlement. Initially they scored a number of successes, but subsequently it appeared that the B-52 ECM equipment was more than a match for such ECCM equipment as the North Vietnamese had available.

The Soviet designation for the missile – or one version thereof – is believed to be V750VK and that of the complete weapon system – including radar and power supplies – V75SM. The system is land mobile, the missile being mounted on a Zil 157 cross-country semi-trailer transporter-erector.

Various models of the missile have been observed over the years exhibiting relatively minor changes in external appearances. The details given below relate to a type that was supplied to Egypt, but it is known that later versions exist. In particular, one that was seen in Moscow in 1967 is somewhat longer and has a larger warhead.

CHARACTERISTICS

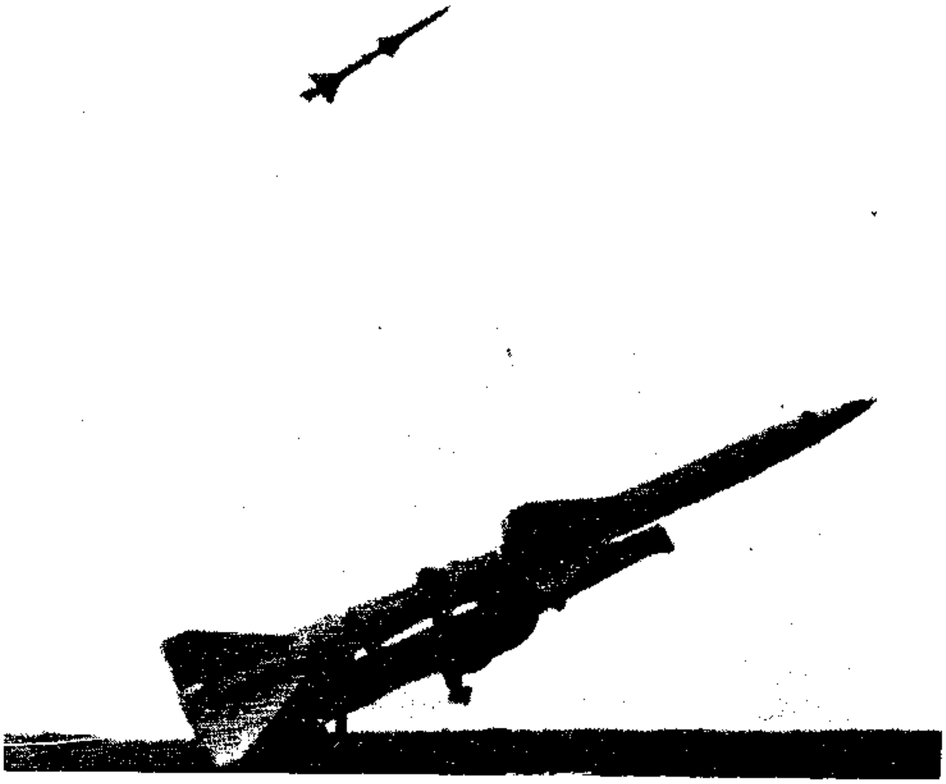
Type: Surface-to-air tactical guided missile
Guidance Principle: Radio command
Guidance Method: By control of movable tail surfaces
Propulsion: Solid-propellant booster with liquid propellant sustainer
Warhead: High-explosive 130 kg
Missile Length: 10.7 metres
Missile Diameter: Booster: 70 cm. Second stage: 50 cm
Launch Weight: About 2 300 kg
Slant Range: 40-50 km
Ceiling: 18,000 metres

OPERATION

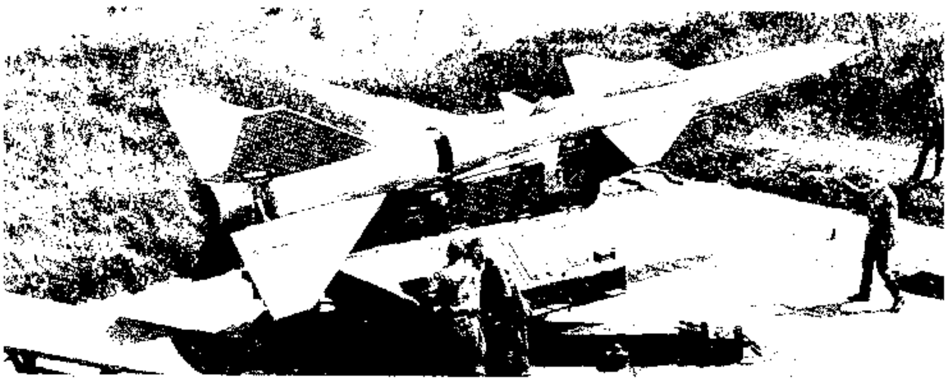
The radio command guidance system is believed to be quite straightforward. Targets are tracked by radar which feeds data to a computer; this in turn produces signals which modulate the output of the command transmitter. Two sets of four strip antennae are mounted fore and aft of the missile wings to receive these signals.

Radar used in conjunction with these missiles is generally that known to NATO as Fan Song (**2866-2868.153**). It is said that one problem with the fire control and guidance system is that the missile must be gathered to the radar beam in the first six seconds of flight or it will not be acquired at all.

According to reports published in the American press concerning Israeli experiences with Egyptian Guideline installations, it was at first found that Israeli ECM devices were adequate to deflect the beam-riding missiles. Subsequently, however, improved missiles were introduced having terminal guidance radar with a wider range of frequencies than the Israeli ECM could handle. They were, however, able to obtain improved ECM pods from the USA which they successfully used to jam the missile acquisition, tracking and guidance systems. When attacked by Egyptian surface-to-air missiles during the 1973 war, indeed, it was reported that the SA-2 and SA-3 missiles caused the Israelis few problems, their main difficulties were with the SA-6 (**2930.131**) and SA-7 (**2941.131**).



Guideline launch (Tass)



Guideline surface-to-air missile on launcher. Note the small nose fins and the control surfaces on the booster fins

Guideline missile with enlarged warhead first displayed in November 1967. Note the fin changes and the absence of control surfaces on booster fins

Various warhead and fuse arrangements have been reported. Most of the missiles have high-explosive warheads but contact proximity and command fuses have been reported. Furthermore, the larger version of the missile referred to above as having been first seen in 1967 is believed to have a nuclear warhead.

STATUS

Operational in the armed forces of the USSR and many other countries. Since the Russian authorities generally appear reluctant to discard from their inventory any weapon which continues to work reasonably well it is likely that Guideline will remain in service for some years yet. Despite various modifications however it is now technologically obsolescent and unlikely to be very effective against an enemy able to deploy reasonably sophisticated ECM equipment.

2938.131
SA-3 (GOA) SURFACE-TO-AIR MISSILE

DESCRIPTION

Goa is the NATO code name for an anti-aircraft guided missile for use both by the Soviet Army and by the Soviet Navy.

Small enough to be carried in pairs on the vehicle that is used as a tractor for the trailer transporters of both Guideline and Guild, Goa is a two-stage missile that is thought to have been intended for much the same operational role as the US Hawk – that is to say, short-range defence against low-flying targets.

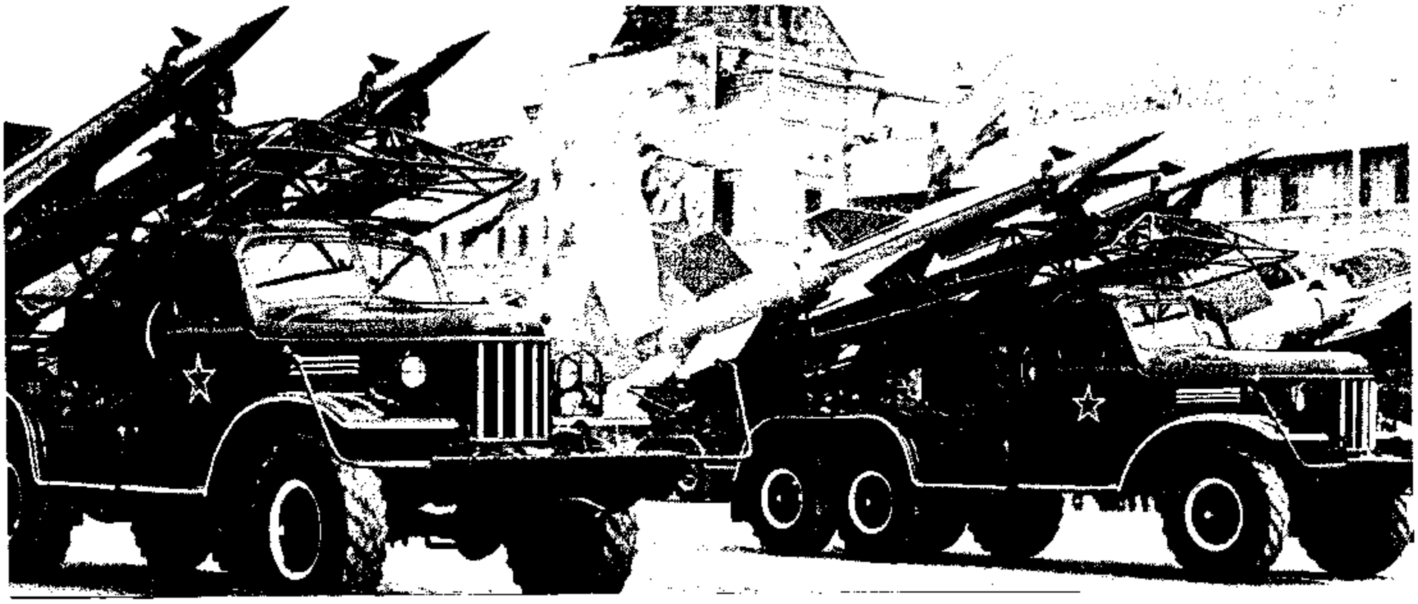
Control of the missile in flight is by movable foreplane surfaces, the rear mounted wings of the second stage being fixed. Considering the operational role suggested above it seems possible that the missile has some form of homing device in the nose; if so, the positioning of the control actuators in the same part of the missile would make a compact guidance package. Basically, however, it seems fairly definite that Goa is a command-guided weapon.

Recently the Goa missile has become much more widely known by its US alphanumerical code SA-3 (or SAM-3) particularly at the time when it was being extensively deployed in Egypt.

Goa is used in conjunction with an X-band fire control radar whose NATO code-name is Low Blow (**2884.153**) and is commonly associated with an acquisition radar code-named Flat Face (**2874.153**). In the linked installation of Goa and Guideline (SA-2, **2942.131**) missiles built by the Egyptians, with Russian assistance, near the Suez Canal in 1970, the Goa missiles were mounted on substantial trainable launchers, contrasting with the simple mobile ramps from which they are normally launched. Tracked vehicle mountings have also been seen.

In addition to its land-based uses Goa is extensively deployed on ships of the Soviet Navy. Further details can be found later in this section (**2939.231**)

CHARACTERISTICS:
Type: Shipborne or land-based surface-to-air guided missile
Guidance Principle: Probably command-guided but a homing system may be incorporated
Guidance Method: By control of movable fore-plane surfaces
Propulsion: Two-stage solid-propellant
Missile Length: 6.7 metres
Missile Diameter: Booster: 60 cm. Second stage: 45 cm
Range: 25-30 km



Goa two-stage surface to-air missile

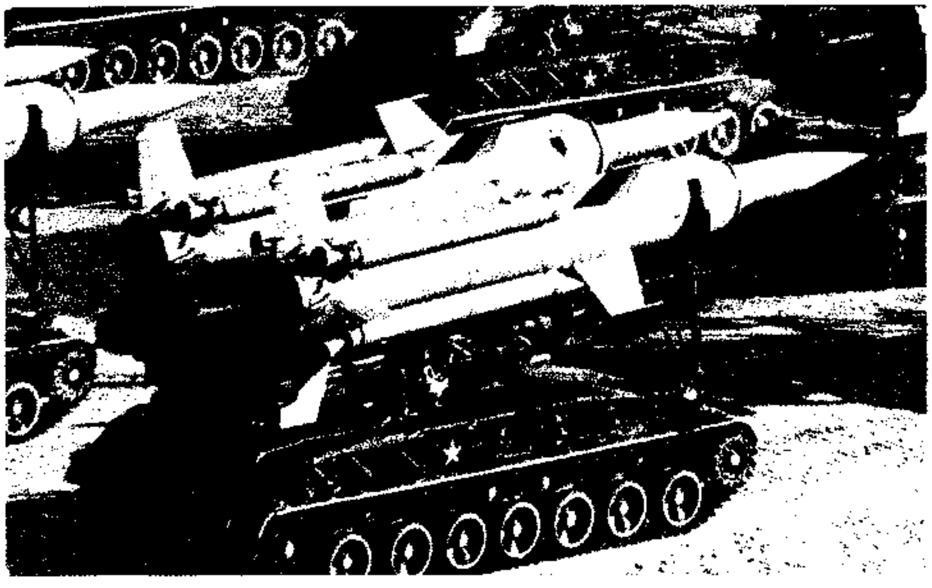
2934.131
SA-4 (GANEF) SURFACE-TO-AIR MISSILE

DESCRIPTION:

Ganef is the NATO code name for a surface-to-air missile launched from a tracked vehicle that was first seen in public in Moscow in 1964. Its US alphanumeric code is SA-4.

Two missiles are mounted on the armoured launcher from which they can be raised into the firing position. The system is thus highly mobile and can be brought into action rapidly: it can also be airlifted by such aircraft as the An-22 heavy freighter. The use of an armoured launcher suggests operation in forward areas and it is believed that the missile can also be used in a ground-to-ground role. For target acquisition and fire control a separately mounted C-band radar whose NATO code-name is Pat Hand (**2936.153**) is used Longer range surveillance is believed usually to be provided by Long Track radars (**2937.153**) which are also used with other mobile Russian missiles.

CHARACTERISTICS:
Type: Land-mobile surface-to-air tactical guided missile
Guidance Principle: Command guidance
Guidance Method: By control of moving wings on forepart
Propulsion: Ramjet sustainer with four solid-propellant boosters
Missile Length: 9.0 metres
Missile Diameter: 0.8 metres
Launch Weight: About 1,000 kg
Range: About 70 km



Ganef ramjet-powered surface-to-air missile (Tass)

STATUS:

Ganef is an operational missile widely deployed in Russia. It was also at one time deployed in Egypt; but since it appears not to have been used in the 1973 Arab-Israeli war it seems likely that the missiles have been withdrawn – possibly in exchange for the SA-6 Gainful missiles (**2930.131**) which were used in the war.

2930.131
SA-6 (GAINFUL) SURFACE-TO-AIR MISSILE

DESCRIPTION.

Gainful is the NATO code name for an anti-aircraft missile system known in the US alphanumeric code as SA-6 and first publicly shown in Moscow in 1967.

Until the 1973 Arab-Israeli war little was known about Gainful in the West. The missile system was, however, used extensively in that war – this being, so far as is known, its first operational use – and scored a number of successes in the early phases of hostilities The Israelis, however, were able to capture some of the missiles more or less intact and some information on their construction and performance has become available.

Gainful is both a command guided and a homing missile and is fully mobile, both missile launchers and fire control radar systems being mounted on separate tracked vehicles. The fire control system is both sophisticated and, it would seem, effective. It comprises a primary search and acquisition radar, a target tracking and illuminating radar, a command link with secondary radar response for missile tracking and a missile-borne semi-active homing system. In ECM conditions some of the tracking functions can be performed optically.

The ground equipment of this complex is known by the NATO name Straight Flush (**2885.153**). Its limitation would appear to be a restricted search capability when operating without the support of other types of surveillance radar Precise data regarding frequencies used for the functions enumerated above have not reached us, but it seems fairly clear that the search/acquisition function is carried out in the 6 6 GHz band, the target tracking illuminating function in the 8 10 GHz band and the command guidance and beacon response is also in the 8 10 GHz band though obviously not on the same frequencies. This sort of C-band X-band combination is of course not unlike that used in some Western missile systems of similar age.

The missile is constructed as a single-stage body containing a dual-thrust integral rocket-ramjet propulsion system. In the boost phase the missile is powered by a solid propellant rocket motor which accelerates it at about 20 g to about Mach 1.5. With the completion of this rocket burn the tail cone of the missile, which contains the booster nozzle is jettisoned and the rocket propellant chamber becomes the combustion chamber for the ramjet, ram air being supplied through four intakes disposed symmetrically around the centre section of the missile. The ramjet takes the speed up to almost Mach 2.8.

Two sets of cruciform fins at the centre and tail of the missile provide stability and aerodynamic control, pitch and yaw being controlled at the centre and roll at the tail. The tail fins also carry the command link receiver aerial and the beacon transmitter aerial. The nose of the missile is an ogival radome for the homing head.

CHARACTERISTICS

Type: Surface-to-air tactical guided missile

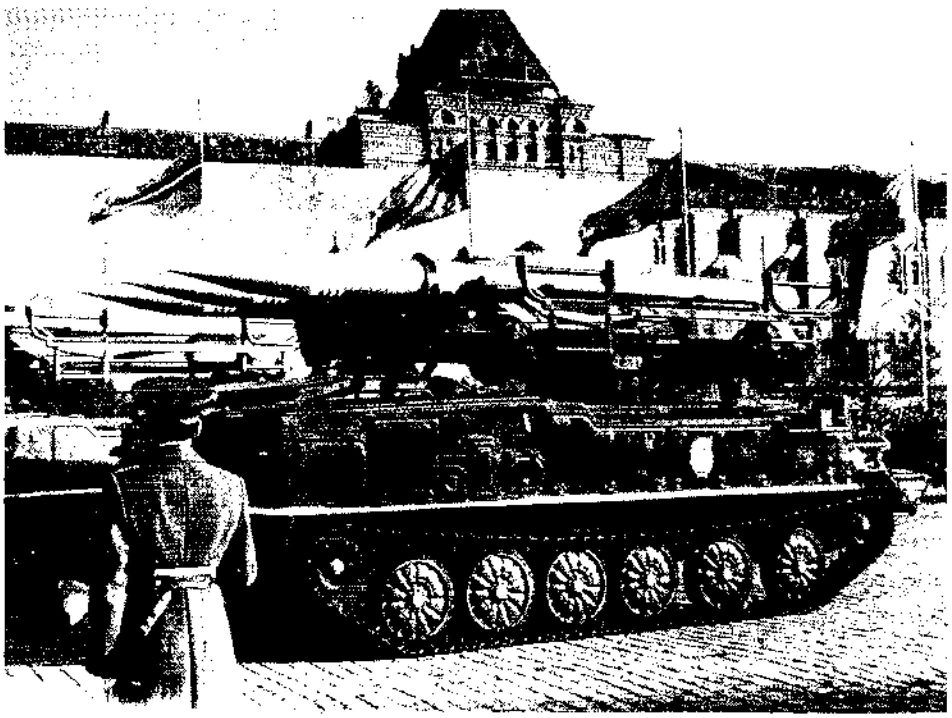
Guidance: Ground command plus semi-active radar homing. Aerodynamic control

Propulsion: Integral rocket-ramjet

Warhead: High explosive, probably 80 kg total with 40 kg HE

Fuse: Proximity and impact; possibly also command

Missile lengths: 6.2 m including tail cone, 6.0 m without



SA-6 Gainful missiles (Tass)

Diameter: 33.5 cm

Tail Span: 124 cm

Launch Weight: about 550 kg

Ranges: Maximum, high-altitude possibly 60 km, low altitude probably 30 km. Maximum altitude about 18 km. Minimum engagement about 4 km. Minimum altitude about 100 m by radar or perhaps 50 m with optical tracking

STATUS

Operational. Warsaw Pact countries and Egypt.

2964.131
SA-9/10 SURFACE-TO-AIR MISSILE SYSTEMS

Information from US sources contains references to two new surface-to-air missile developments in the USSR.

Virtually no details are available apart from the statement that one of the missiles (SA 9 ?) is designed specifically for low-altitude interceptors and has an active radar homing system and the speculation that the other might be intended to fill the range-altitude gap between Gainful and Ganef (**2930.131** and **2934.131**).

It is understood that the US alphanumerical code numbers SA 9 and SA 10 have been allotted to the two new developments. It will be observed that this means that the number SA-8 has apparently been omitted from the sequence, and we have no further information that will explain this omission.

STATUS:

Presumably advanced development.

MOBILE GUN AND ROCKET SYSTEMS

FRANCE

2110.131
JAVELOT SURFACE-TO-AIR WEAPON SYSTEM

DESCRIPTION:

Javelot is a mobile anti-aircraft multitube rocket firing system currently being developed by Thomson-CSF in collaboration with Thomson-Brandt.

Two versions of the system are proposed – Javelot for mounting on tanks or other armoured vehicles and Catulle for mounting kill on small or medium-sized warships. Each system comprises a multitube gun effect rocket launcher capable of firing salvoes of rockets with predetermined dispersion, an acquisition radar, a fire control radar and a digital computer.

PROPOSED CHARACTERISTICS:

Function: Anti-aircraft protection of AFV's or motorised units

Surveillance element: Coherent pulse-Doppler surveillance and target acquisition radar

Tracking element: Auto-follow pulse-Doppler fire control radar

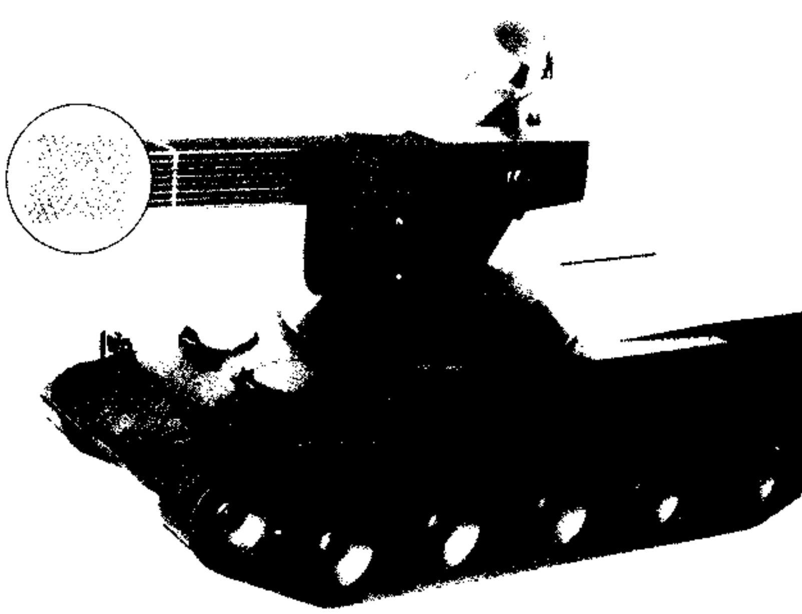
Weapon Aiming: Digital computer processing radar data

Weapon: Multitube gun launcher firing 40 mm rockets

Efficiency: 70% kill probability at 1500 metres

Reaction time: 2-4 seconds interval between target engagements

General: Large fire capacity without reloading Light weight – suitable for mounting on light AFT's or medium tanks



Model of Javelot system with, inset, a diagram of the launching tube pattern

STATUS:

Work is proceeding on a contract awarded to Thomson-CSF and Thomson-Brandt by the D.T.A.T. for the study of Javelot. The project is financed jointly by the French and US Governments and has been studied in the USA.

MANUFACTURER:

Principal: Thomson-CSF, 1 rue des Mathurins, 92222-Bagneux.

2164.131
M3 – VDA AA GUN SYSTEM

DESCRIPTION:

This Panhard/EMD system combines the firepower of many heavier SP AA gunsystems with the low cost lightness and high mobility of the Panhard M3 vehicle. It comprises a one-man gun turret mounted on the specially-adapted M3 and carrying a pair of HSS 820 SL guns; a weapon control system with a display for the vehicle commander; and the vehicle itself which is driven by the third member of the crew.

The weapon control system comprises a radar (or alternatively an optical observation system), a computer sight and high-speed controls for the twin guns and feed system.

The EMD radar is an X-band pulse doppler surveillance/acquisition device with a detection range of about 8 km (2 sq m target) and a rotation rate of 40 rev/min. Targets are displayed on the commander's console; and in target designation the radar feeds target bearing to the optical sighting system and range and target velocity to the Galileo computer sight. The gunner keeps the optical sight trained on the target and the computer calculates lead angle and favourable engagement conditions.

For the simpler (and cheaper) version of the equipment the radar is replaced by two optical observation posts, one for the commander and one for the gunner, with overlapping arcs of observation to give full 360° coverage. When one or other observer is tracking a target the tracking movement generates signals from which the computer calculates lead angle and engagement data as before. The absence of direct range and velocity measurements, of course, makes smooth tracking essential if reasonable accuracy is to be achieved and to this extent the non-radar version is more demanding than the other.

CHARACTERISTICS:

Vehicle characteristics: Generally similar to the M3-VTT (5022.102)

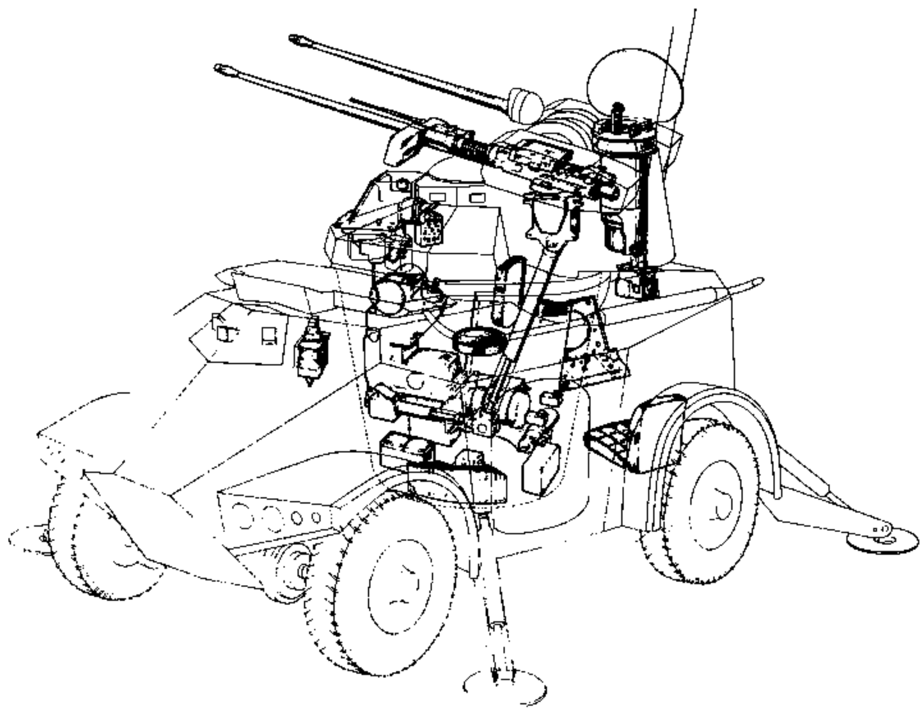
Combat Weight: 6,300 kg

Road speed/Range: 90 km/h/1,000 km

Armament: 2 HSS 820 SL or similar 20 mm cannon. HSS weapon has MV 300 m/sec slant range 2,000 m maximum engagement altitude 1,500 m. Rate of fire 800-1050 rounds/min. 600 rounds (2 × 300 belts) carried

Radar: EMD pulse doppler

Computer Sight: P56-Galileo



Layout of M3-VDA units

STATUS:

Prototype. Exhibited at Satory in 1973. Versions in larger Panhard vehicles are contemplated.

MANUFACTURERS:

System: Société de Constructions Mécaniques Panhard et Levassor, 18 Avenue d'Ivry, 75013-Paris, France.

Radar: Electronique Marcel Dassault.

Computer: Officine Galileo.

2138.131
SELF-PROPELLED 30 mm TWIN-GUN ANTI-AIRCRAFT WEAPON SYSTEM

DESCRIPTION:
This is one of several systems that have been developed in recent years in which an AA gun turret is mounted on a tank chassis and provided with its own fire control radar, the whole being used for the defence of forward (and especially armoured) units against attack by low flying aircraft.

DESCRIPTION:
The system comprises a SAMM (Société d' Applications des Machines Motrices) gun turret Type S401A with twin Hispano 30mm guns mounted on an AMX30 tank chassis. At the rear of the turret is mounted the aerial of a Thomson-CSF Oeil Noir radar, the electronics of which are contained within the turret. The aerial, is mounted on a bracket that allows it to be folded down when not in use to reduce the height of the system. The turret is fitted with optical sights and the guns can be laid and fired with these alone if the radar is inoperative.

OPERATION:
In its surveillance mode the radar scans continuously in azimuth, threat evaluation techniques being used to help the operator to select the most dangerous target (see description of Oeil Noir radar **2129.153** (Section 3 below). On selecting a target the turret is brought to the correct bearing and the gunner engages it visually using range data supplied by the radar.

SP 30 mm Twin-gun AA system on AMX-30 chassis

DEVELOPMENT:
Development was initiated by DTAT, and a version of the system mounted on an AMX-13 chassis has been in service with the French Army since 1965. The new version mounted on an AMX-30 chassis, is an improvement in terms both of utility and of mobility. In particular, mounting the system on the AMX-30 makes possible of a larger supply of ammunition; and the tank's self-contained power supplies are valuable for the watchkeeping role.

MANUFACTURERS:
Design Authority: DTAT (Direction Technique des Armements Terrestres).
Project Leader: GIAT (Groupement Industriel des Armements Terrestres), Caserne Sully, 10 place Georges Clemenceau, 92211 Saint-Cloud, France.
Turret Type S401A: Société d'Applications des Machines Motrices, 224 Quai de Stalingrad, 92130-Issy-les-Moulineaux, France.
Guns Type 831A or 831 SL/75 Cal 30 mm: Hispano-Oerlikon, 110 Route de Lyon, Geneva, Switzerland.
Radar Type DR-VC-IA (Oeil Noir): Thomson-CSF, 1 rue des Mathurins, 92222-Bagneux, France.

GERMANY (FEDERAL REPUBLIC)

2182.131
20 mm TWIN-GUN ANTI-AIRCRAFT SYSTEM

DESCRIPTION:
The AA 20 mm Twin Gun is a light highly mobile automatic system for the engagement of low-flying aircraft. It can also be used to engage ground targets.

Comprising two automatic rapid-fire guns with an analogue computer sight mounted on a transportable chassis that incorporates the gunner's seat, the system is suitable for rapid deployment in forward areas. The system is operated by a single gunner: to replenish ammunition two men are required and to bring the equipment into or out of action a third man is necessary.

A two-wheel trailer is used to transport the system and can be towed by any vehicle capable of handling an unbraked-trailer weighing 2500 kg. The trailer is detached when the equipment is brought into action, the system then being supported by a sturdy carriage with levelling outriggers. To this lower carriage is fixed an upper carriage that carries the laying mechanism, the gun cradle and the gunner's seat.

The laying mechanism is mounted over the rear bearings of the upper carriage. It carries the laying mechanism with its laying devices and consists of the following items:

- air cooled, two-stroke petrol engine with a centrifugal clutch.
- hydrostatic drives for elevation and traverse powered by an axial piston pump and motor.
- the housing, with integrally-cast cooling fins, serving as an oil tank.
- hydraulic dampers for extremes of elevation swing.
- control elements and transmission linkages.
- hydraulic systems.

Ample power is available so that the control elements can be made very sensitive. The laying mechanism thus facilitates very rapid acquisition of a target and smooth tracking.

During action against ground targets, or in anti-aircraft operation should the hydraulic system fail, the equipment can be laid manually. There is a changeover switch from normal to manual operation and handwheels are used to elevate and traverse the guns.

The fire control equipment is mounted on the laying mechanism and a shield is fitted to protect the gunner against pointed steel-core armour-piercing bullets.

The equipment consists of a lead computer of high accuracy, the target tracking device, the optic and the drive for the lead marks in the optical AA sight. At the start of the engagement the gunner calculates and manually sets the estimated target speed and the probable or ordered range to crossing point on the lead computer. As soon as tracking begins true information is mechanically fed into the lead computer which calculates the data used for controlling the lead marks in the monocular AA sight.

The upper reticle has an aiming mark in the form of a bar which pivots on one end and represents the apparent direction of flight. The lower reticle has a slightly curved spiral arranged to rotate about its optical axis.

It is the gunner's job to bring the point of intersection of the aiming bar and the spiral into coincidence with the target. Thereafter the gunner uses his knee to switch on the tracking aid. The tracking rates, determined by the lead computer, are transferred to the gears directly below the joystick and from there almost error free, through the gunner's controlling hands to the joystick and hence back again into the fire control system. To acquire the target the sight mounted on the gun shield is used.

A second eyepiece on the fire control equipment is the telescopic sight for ground targets. It operates as soon as the mask has been switched over the aperture of the AA sight. Ranges for ground targets of up to 4000 metres can be set on the ground sight.

A valuable feature of the fire control system is the programmed "taboo" facility. This is a safety device to prevent friendly targets from being accidentally engaged. It essentially consists of an electronic control mechanism, an azimuth and elevation coder, and a switch box which also includes a switch for storage and erasure of the data obtained.

The taboo facility divides the field of fire into a combat zone and a neutral zone. Below the boundary between combat and neutral zone the guns cannot be fired. Fire is reliably interrupted if the guns are swung into the neutral zone while tracking a target.

To programme the taboo interlock the gunner tracks along the boundary line delineating the area not to be engaged. The limits in elevation lie between −5° and +40° i.e. −90 to +700 mils and laterally all round. He tracks with the optical sight while the taboo interlock records electronically the limits of the neutral zone. Should sudden action against ground targets be necessary the taboo interlock can be temporarily bypassed without delay.

The guns used in the system are the Rheinmetall Rh 202 20 mm rapid-fire guns (**5600.103**). These are precision weapons that have a very high rate of fire (600-1000 rounds per barrel per minute) and a low recoil force. Both gun and ammunition feed are gas operated and independent of weapon and breech movement. In the AA weapon system cartridges can be fed selectively so that either or both guns can be employed during an engagement.

CHARACTERISTICS:

Guns:

Type: 2 Mk 20 Rh 202 rapid-firing guns

Calibre: 20 mm

Cyclic rate of fire: abt 1000 rpm per barrel

Length: 2610 mm

Weight: 76.5 kg

Barrel Centres: 230 mm

Weapon:

Cocking Device: Hydraulic, manually operated, simultaneously cocks both guns

Fire Mechanism: Pedal actuated electro-mechanical (firing solenoid); Mechanical emergency firing

Methods of Fire: Single shot or sustained

Types of Fire: By use of the electrical firing mechanism, right gun, both guns simultaneously, left gun

Supply of Ammunition: 270 rounds belted per gun in ammunition box and the feed mechanism 10 rounds belted per clip

Taboo Facility: Programmable for neutral zone of any shape

Fire Control Equipment: Analogue computer

Estimated Data Input: Target velocity 60 to 350 metres per second slant range to crossing point 200 to 1400 metres

Laying Mechanism (Hydrostatic):

Laying Speeds per sec: Traverse 0° to 100° i.e. 0 to 1830 mils. Elevation 0° to 55° i.e. 0 to 1000 mils

Field of Fire: Traverse unlimited Elevation −5 to 83° i.e. −90 to +1520 mils

AA Gun ready for the road:

Overall Length: 4.500 mm

Overall Width: 2.370 mm

Overall Height: 1.910 mm

Trailer Track Width: 2.080 mm

Weights:

AA 20 mm twin guns ready for firing with 540 rounds of ammunition: 1.450 kg

Chassis: 650 kg

Total weight of AA twin gun and trailer ready for the road: 2.100 kg

Crew:

For Firing: One man

For replenishing ammunition: Two men

Coming in and out of action: Three men

DEVELOPMENT

The AA 20 mm Twin Gun system was commissioned by the German Federal Department of Military Technology and Procurement (Bundesamt für Wehrtechnik und Beschaffung) in Koblenz and has been developed and produced by Rheinmetall GmbH in Dusseldorf.

BOFORS 40 mm ANTI-AIRCRAFT SYSTEM 75

DESCRIPTION:

Based on the Bofors mobile 40 mm L/70 gun (**5528.103**) this new system incorporates a new optronic fire control equipment known as BOFI (**2378.151**), which is integrated with the gun and a new proximity-fused shell. The gun carriage, in addition to the modifications necessary to accommodate the BOFI unit, also incorporates a power supply unit and associated apparatus.

An optical target indication device, separately mounted but carried with and connected to the mobile gun, is a standard part of the system: data from a separate search radar can also be used as an input to the system.

Principal characteristics of the system are:

1. Short deployment time of 3-5 minutes;
2. Effective fire resulting from the accurate, optronic target tracking and integrated construction, together with the use of proxi mity-fused ammunition;
3. Excellent anti-jamming properties resulting from the combination of manual, optical target tracking and gate controlled laser range finding;
4. Night combat properties provided by a light-amplification sight in BOFI;
5. Easy maintenance.

STATUS:

The gun has been in production for several years, and has been supplied to many countries.

Testing of the fire-control equipment was completed during 1972. This equipment is now operational.

Development of the proximity-fused ammunition was completed during 1974.

MANUFACTURER:

AB Bofors, S-690 20 Bofors, Sweden.

Anti-aircraft system 75, which is based on the Bofors 40 mm L/70 gun. New optronic fire control equipment is incorporated in this system. Note the diagram of a new proximity-fused shell at the top of the picture.

SWITZERLAND

2374.131
ANTI-AIRCRAFT FIELD SYSTEM 35 mm TYPE 2 ZLa/353 MK

DESCRIPTION:

The 35 mm twin gun Oerlikon-Contraves anti-aircraft system is fully automatic, and radar-controlled.

The system comprises the 35 mm twin gun, newly developed from basic requirements by Oerlikon-Bührle Ltd with the well proven Super-Fledermaus fire control equipment of Contraves Ltd. The electro-hydraulic system of the gun mounting enables a three man crew to change over from travelling to fire position – including levelling – in only 1½ minutes. The destructive effect of the 35 mm shell is the same as that of the 40 mm Bofors L 70 shell.

CHARACTERISTICS:

Calibre: 35 mm
Muzzle Velocity: 1,175 m/sec
Rate of fire per barrel: 550 rds/min
Rate of fire of gun: 1,100 rds/min
Tactical range: up to 4,000 m
Aiming speed:
Elevation: min 0.05°/sec, max 56°/sec
Traverse: min 0.05°/sec, max 112°/sec
Traverse and elevation drive:
- electric, by remote control
- electric, by gunner using joystick and auxiliary sight
- manual drive, by gunner in case of emergency

STATUS:

In production and already supplied to more than 10 countries.

Gun mounting of the Oerlikon twin 35 mm anti-aircraft gun system

2370.131
ANTI-AIRCRAFT TANK SYSTEMS

These systems had their origin in some basic studies carried out by a working partnership consisting of Siemens-Albis, Contraves and Oerlikon-Bührle Machine Tool Works. The object of the studies was the specification of a mobile, armoured anti-aircraft weapon system that could operate effectively in forward areas to provide protection for combat zone troops from low-level air attack.

It was recognised that the satisfactory performance of this function necessarily involved all-weather capability, fast reaction time, relative immunity to ECM, a high degree of reliability, coupled with the ability to carry sufficient ammunition to enable the system to remain in operation for long periods, and arrangements both to protect the crew from attack and to enable them to defend themselves against ground forces.

DESCRIPTION:

The basic component functions seen to be necessary were, first, an armoured tracked vehicle to carry the system; secondly, an anti-aircraft gun arrangement of adequate fire-power and range; thirdly, a fire control system with associated optical and tracking radar sensors; and, finally, a surveillance radar to detect targets and put the rest of the system on target.

So far, three significantly different systems have been designed – the 5PFZ-A, 5PFZ-B and 5PFZ-C – and the second and third have been modified as a result of further development, following exhaustive technical and user trials, to the latest versions – 5PFZ-B2 and 5PFZ-CA.

Original 5PFZ-A arrangement

5PFZ-A

Development of this version started in 1966, and a contract was placed in that year by the Federal Republic of Germany for two prototypes. Main components of this system were a *Leopard* battle tank chassis by Kraus-Maffei; a 35-mm twin-barrelled gun system by Oerlikon; a fire control system by Contraves; a tracking radar by Siemens-Albis and a search radar with MTI by B.V. Hollandse Signaalapparaten. This last radar was developed on a direct contract to the Netherlands.

The first prototype was delivered in 1968 and the second in 1969. Firing trials and other technical tests carried out in 1969-70 were very successful and were followed by user trials.

5PFZ-CA system

5PFZ-B2 (Flakpanzer 1 – Gepard)

Successor to the 5PFZ-A this model, embodies advanced radar and other electronic techniques. It uses the Siemens MPDR-12 pulse-doppler surveillance radar with integrated MSR400 IFF equipment. The Siemens-Albis tracking radar is of the monopulse-doppler type.

This version has been ordered in quantity to equip the armed forces of the Federal Republic of Germany and Belgium. Deliveries from the Kraus-Maffei assembly line of a series of 420 Gepard tanks for the FRG will start by the middle of 1976.

5PFZ-CA

Second offspring of the 5PFZ-A and preceded by the prototype 5PFZ-C, this model uses an integrated MTI/monopulse-doppler search and tracking radar. A special sharp beam is incorporated in the tracking radar section. Apart from the MSR400 IFF the whole radar is supplied by Signaal.

This version has been ordered in quantity by the Royal Netherlands Armed Forces.

OPERATION (5PFZ-B & C):

Targets are detected and identified by the surveillance radar and IFF – both of which continue to scan throughout an engagement. On detection the crew is automatically alerted; and on target designation the tracking radar automatically acquires it – the mounting of the tracking radar aerial in the turret being such as to give it a target acquisition arc of some 200 degrees without slewing the turret.

Data from the tracking radar enables the fire control computer to calculate the lead angle for the guns (which are fitted with MV measuring equipment, the output of which is also fed to the computer) and to determine the optimum point for engagement. The guns are belt-fed and have a rate of fire of 550 rounds/minute each and an MV of 1,175 m/sec. 680 rounds of ammunition are carried on the vehicle.

Both commander and gunner have periscopes that can be used when necessary for optical target acquisition and tracking, combat zone observation and gun-laying for ground targets. To enable these functions to be performed while the vehicle is on the move, the optical lines of sight are stabilised by rate gyros.

The miniaturised, transistorised computer, the radars and other electronic units are fitted with self-testing equipment whereby the fire control unit can be checked out. An emergency computer is also fitted to which the crew can switch in the event of failure of the main computer.

2407.131
FALCON SP 30 mm ANTI-AIRCRAFT WEAPON SYSTEM

DESCRIPTION:

Falcon is one of several mobile anti-aircraft systems that have been built or proposed in recent years as solutions to the problem of defending military formations on the move from attack by low-flying aircraft or by lightly-armoured highly mobile ground forces.

Most of these systems, whether based on guns or on surface-to-air missiles are dependent for their operation on the use at least of surveillance radar capable of detecting low-level targets and often of tracking radar as well. Falcon marks an interesting departure from this trend in that it has no radar (although the possibility that someone might wish to fit radar to it is recognised) but instead depends on a highly sophisticated visual aiming system.

The arguments in favour of such a system are that it is not vulnerable to ECM and that it is significantly cheaper than a radar-equipped system. The manufacturers argue, however, that it is nevertheless as effective operationally as radar-equipped systems using the same basic weapons.

DESCRIPTION:

Major components of the system are the Vickers Abbot chassis, a specially-designed turret, Hispano Suiza 30 mm guns and a specially-designed fire control system built round a periscope optical sight.

The Abbot armoured chassis is described in Section 3 (**5503.103**) and all that need be said here is that it is a firmly established design that gives good off-road mobility – including a useful wading capability – air transportability and operational simplicity. On it is mounted a specially-designed turret which is fabricated in steel armour plate and gives protection against shell splinters and small arms fire.

Access to the crew compartment is through two hatches in the roof, above the commander's and gunner's seating positions. These are side-by-side adjustable seats. The commander's seat is designed to allow him to sit in the 'head out' position. The crew compartment is sealed from the gun and ammunition compartment thereby assuring an atmosphere free from fumes, and reducing the noise threshold when firing the weapons.

The weapons installed are the Hispano Suiza 30 mm calibre Type 831L. These are mounted in coupled gun cradles which are externally of armoured steel. Access for mounting and dismounting the guns for maintenance is simplified by the provision of a front cover on each cradle and the fact that the gun barrel is bayonet fitted into its gun body.

Ammunition is fed to the guns from boxes located in the base of the turret through chutes into belt feed mechanisms operated by gun recoil. Empty cartridge cases and the belt links are ejected sideways through the elevation trunnion bearings.

The guns are cocked and fired electrically, single shot and automatic fire from both or either gun being selectable. They fire at a rate of 650 rounds per minute from each barrel: this high rate of fire being one of the essential reasons for the attainment of the high hitting probability of the system.

The power control system controls and drives the turret in traverse and the twin gun in elevation, providing high speed slewing and maintaining accuracy of aim, even with one gun firing. The gun is also stabilised against vehicle movement. The system is similar to those developed by GEC-AEI (Electronics) Limited, for use in the Centurion and Chieftain tanks, and the Vickers Main Battle Tank.

The gunner tracks the target by operating a two-motion joy-stick which is energised when a foot pedal is depressed. The commander has a similar joy-stick which can override the gunner's.

The power control system is all-electric. Signals from the joysticks are compared with the outputs from rate gyro units mounted on the gun cradle, the resultant error signal being processed in amplifier channels to optimise the response and convert it into a suitable signal for controlling rotating amplifiers (metadynes). The metadyne outputs control servo motors which drive the turret and twin guns through gearboxes.

The gunner is provided with a periscope gunsight with dual optical systems – one of X1 magnification and a 50 degree field of view for anti-aircraft use and the other of X6 magnification with a 10 degree field of view for accurate laying on ground targets.

Superimposed on the anti-aircraft field of view is a moving circle, the displacement of which from the optical centre line is the lead angle for maximum hit probability. This lead angle is computed by automatically feeding the rate of tracking speed into a simple computer and multiplying this by a factor representing the present range of the target. In practice the guns would be intentionally fired at a range longer than the manually set range, and firing continued until the actual range is shorter than the manual set range. In this way it can be assured that any normal error in estimating the range of the target is covered by the bracketed range of fire. In short the use of the sight will be identical to the gyroscopic gunsights used for many years, but the periscopic gunsight as installed enables the turret to be used with complete cover for the crew.

The commander has a similar periscopic gunsight but without the moving lead angle display. Both the gunner's and commander's sights have emergency fixed graticules. Both sights are also provided with a ground target ballistic graticule which has the following features:

1. It gives the variation in tangent elevation (gravity drop) for different ranges.
2. The length of the graticule marks at each range are calculated to be identical to the width of a typical APC. This feature gives a form of stadiametric ranging.
3. Lateral deflection is possible by graticule marking at 5 milli-rad intervals.

These facilities are in the X6 magnification periscopic sight, and additional observation periscopes are provided for the commander.

Maximum engagement range is 3,000 metres.

2843.131

AVADS – AUTOMATIC VULCAN AIR DEFENCE SYSTEM

DESCRIPTION:

AVADS is the acronym for an "automatic" version of the established Vulcan Air Defence System (**2850.131**). The principal feature of the automation of the system is the replacement of the radar/optical tracking system of the VADS by a system relying primarily on an auto-tracking radar – the range-only radar of the earlier system having been modified to give it an angle tracking capability (see **2844.153**).

Associated with this modification are the replacement of the gyro lead-computing sight by a helmet sight, which greatly speeds target acquisition, the addition of a solid-state analogue computer for fire control and the incorporation of a self-test unit. The whole is mounted in a M-113 APC (as is one version of the VADS) and solid-state electronic turret drives have been added. Total weight of the whole system is now some 2,350 kg.

OPERATION:

The system can be operated in any one of five modes:

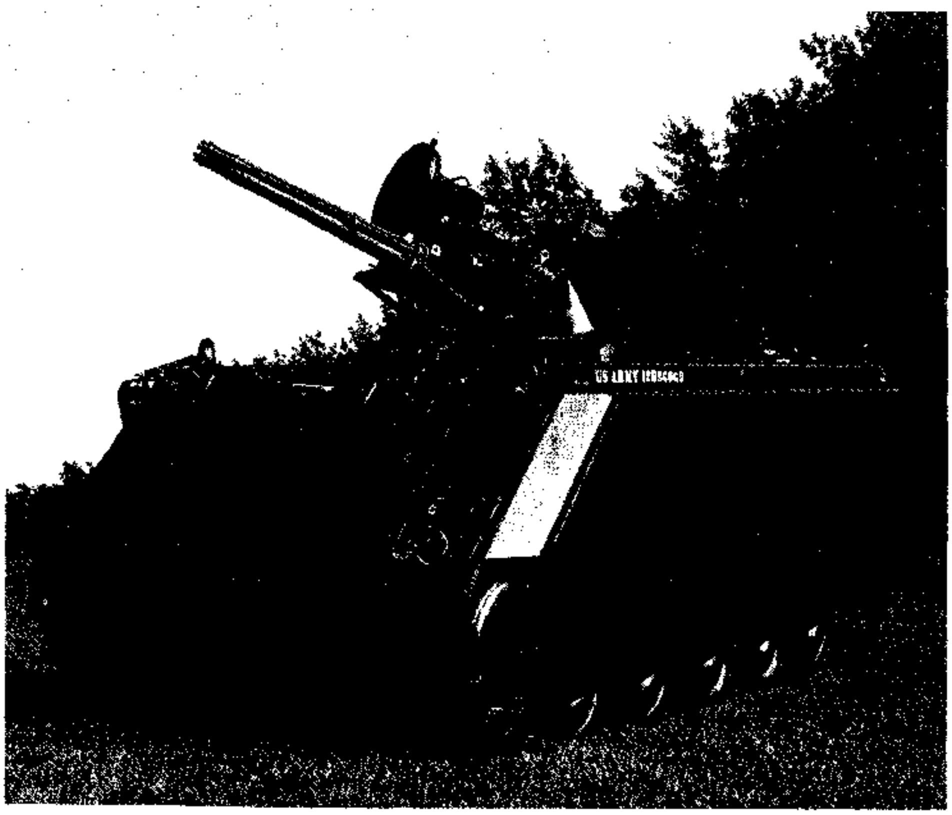
1. Helmet sight acquisition/automatic track
2. Ring sight acquisition/automatic track
3. Helmet sight track/range-only radar
4. Helmet sight track/estimated range and range rate
5. Ground mode.

The first of these modes is the most fully automated. As the gunner, aided by his helmet sight, searches for the target, the radar aerial (not radiating) and the turret (in low gain mode) follow his line of sight. When the gunner has acquired the target optically he operates the trigger – which then transfers control of the engagement to the automatics. The radar radiates, locks on and tracks the target; the computer calculates the correct lead angle and directs the turret appropriately; on being signalled that the gun is laid 'on' and when the radar indicates that the target is 'within' engagement range, the computer commands the firing of 2-second bursts until the gunner releases the trigger.

CHARACTERISTICS:

Gun: M-168, 20-mm Vulcan

Weight:
Feed System: 545 kg
Mount: 1,400 kg
Gun: 136 kg
Ammunition: 282 kg
Total: 2,363 kg



Automatic Vulcan Air Defence System

Firing Rate: 1,000/3,000 spm
Ammunition Capacity: 1,100 rds
Feed System: Linkless, single-ended
Drive System: Electric
Power Requirements: On-station batteries require 500 watts standby
Ammunition: M-50 series
Barrel Life (Per set): 20,000 rounds
Slewing Rates: Azimuth: 80°/second. Elevation: 60°/second
Train/Azimuth Limits: None, 360° continuous
Elevation Limits: +80 degrees, −5 degrees
Diameter of Main Bearing: 1,016 mm
Recoil Force (Average):
At 3000 spm: 818 kg
At 1000 spm: 273 kg
Fire Control:
Radar: X-band, pulse-doppler tracks in range and angle. 200-5,000 metre range.
Computer: Linear straight line prediction, solid-state, provides ballistics for 5 different projectiles.
Helmet sight: Electro-mechanical, used for acquisition, allows gunner to perform 360° search

STATUS:

Army evaluation relative to such competing systems as the naval Phalanx system (**2543.231**), the 30 mm gun project GLADS (**2544.131**) and the French Javelot (**2110.131**). Basic fact-finding evaluation is believed to be complete but no news of a decision has been received.

MANUFACTURER:

Systems prime contractor: General Electric Company, Lakeside Avenue, Burlington, Vermont 05401, USA.

2544.131

GLADS LOW-ALTITUDE DEFENCE SYSTEM

DESCRIPTION:

GLADS (or GLAADS), an acronym for Gun Low-Altitude (Air) Defence System, is the name given to a point or area defence system now being considered by the US Army.

Aimed at producing a system to combat low flying aircraft, the concept has much in common with the established Vulcan air defence system (**2850.131**) but is built around a larger-calibre gun than the General Electric 20 mm weapon used with Vulcan.

Envisaged as a self-propelled system GLADS will have, probably, either a 25 mm or 30 mm gun, an improved fire control sensor and a digital processor. A laser rangefinder is likely to be incorporated as also is a forward-looking infra-red (FLIR) imaging device. Possible suppliers of the gun are General Electric and Philco-Ford, both of whom have multi-barrel weapons of appropriate calibre in hand for other projects.

STATUS:

Project. A decision on its future will depend on the US Army assessment of its potential relative to the AVADS system (**2843.131**) a version of the Phalanx system (**2543.231**) and the French (American-assisted) Javelot system (**2110.131**).

2850.131
VULCAN AIR DEFENCE SYSTEM

DESCRIPTION:

This is an anti-aircraft weapon system based on the Vulcan 20 mm six-barrel gun. The gun was originally designed for aircraft use but has lent itself readily to integration in a sophisticated light anti-aircraft system.

For different operational purposes the weapon system can be made available on a variety of platforms – as a towed trailer, on a self-propelled land vehicle or mounted permanently on a ship or in a static air defence gun emplacement. The main functional units are the same in each case, however, and the description that follows relates to the towed trailer version of the system.

The system comprises the Vulcan gun, a linked ammunition feed sub-system and a fire control sub-system all mounted in an electrically-powered turret. The fire control sub-system consists of a range-only radar and a lead-computing gunsight with its associated current generator. The towed VADS system contains its own batteries and is equipped with a petrol-driven generator for recharging; and the whole system is mounted on a gun carriage.

THE GUN:

The Vulcan gun, previously used as aircraft armament at rates as high as 6,000 shots per minute, has been modified for the air defence application to provide alternative firing rates of 1,000 and 3,000 shots per minute. Because of the weapon's six-barrel design, its dispersion pattern can be optimised by a suitable choice of muzzle adapter. The adapter chosen causes the pattern to be spread, which results in a higher hit probability.

AMMUNITION FEED:

In the towed system a conventional belt feed is used for ammunition, the belted rounds being fed from a 300-round container. In other systems where more space is available a linkless feed system can be used and this has a capacity of 1,100 rounds.

TURRET AND CONTROL:

The turret is electrically driven and its drive is controlled by three solid-state servo amplifiers. Both the amplifiers and the DC motors they control are interchangeable and readily replaced. Despite the high slew rates attainable the turret motion is smooth.

FIRE CONTROL:

The fire control system consists of a gyro lead-computing gunsight and a sight current generator. The gunner visually acquires and tracks the target with the gyro lead-computing gunsight. The antenna axis of the radar is servoed to the optical line-of-sight, and the radar supplies target range and range-rate data to the sight current generator. These inputs are then processed to provide outputs that are used to control the gunsight.

With inputs of range, range rate, and angular tracking of the optical line-of-sight (measured by a freely gimballed gyro), the sight automatically computes the future target position and adds the required super-elevation to hit the target.

Turret fire control is a disturbed line-of-sight system. The sight case and gun bore are physically fixed in alignment, but the sight reticle, which defines the optical line-of-sight, is positioned by the gyro and is displaced from the gun bore as the gunner tracks the target, thereby establishing the

Vulcan Air Defence System. XM-167 towed version

proper lead angle. The amount of optical line-of-sight displacement is dependent on the range and range rate inputs to the sight, and the required tracking time to establish the lead angle is about one second.

The range-only-radar, developed by the Lockheed Electronic Company, is a coherent doppler, moving target indicator (MTI) radar. It will acquire targets up to 5,000 metres away.

A green light appears in the sight optics signalling that the radar has acquired the target and that the target is within the effective range of the turret system: so that the gunner simply acquires the target in the sight reticle, tracks the target, and fires after the green light appears.

ALTERNATIVE MODE:

When desired, the gunner may switch to a manual mode of fire control. In this mode he must estimate target range and speed and set the estimates on indicator dials on the control panel. The gyro lead-computing gunsight then computes the lead angle based on these estimates.

Trained gunners can achieve good results using the manual mode of fire control, as was demonstrated during the Military Potential Tests conducted by the US Army.

SYSTEM POWER:

Power for the turret is supplied by 24-volt nickel-cadmium batteries within the turret. One battery furnishes power to the turret power control and fire control system; a second drives the Vulcan gun with conventional linked ammunition, but a third battery is required when the linkless feed system is used. Batteries can be charged by an on-vehicle generator or a portable auxiliary power unit. The turret can remain in standby condition over long periods of time without significant power drain.

CHARACTERISTICS (TOWED TYPE):

Type: Land-mobile, air-transportable, light anti-aircraft weapon system

Control: Radar ranging, optical aiming, automatic lead computation

Fire Power: 6 × 20 mm guns. 3,000 spm high rate of fire. 1,000 spm low rate of fire

Radar Range: 5,000 metres

Weapon Coverage: Azimuth 360 deg. Elevation:- 5 deg to +80 deg

Turret Slewing rate: Azimuth 60 deg/sec. Elevation 45 deg/sec. Acceleration 160 deg/sec^2

Height on Wheels: 2.03 metres

Height Emplaced: 1.73 metres

Wheel Track: 1.77 metres

Weight: 1,360 kg

Standby Power Requirement: 500 W

DEPLOYMENT:

The US Army, after successful military potential tests in 1964 and 1965, selected the Vulcan Air Defence System to arm new Composite Air Defence Battalions. The Vulcan system is used in conjunction with the Chaparral missile system in the composite battalion.

The Army is using two VADS configurations; the M-163 Self-Propelled and the M-167 Towed. For the Self-Propelled M-163; the turret is mounted on a modified M113A1 armoured personnel carrier (designated M-741 for this application) and uses a linkless ammunition feed system. It maintains the swim capability of the M113.

For the towed M-167, the system is mounted on a lightweight, two-wheel gun carriage and uses conventional linked ammunition in a 300-round container. It is helicopter transportable and uses the M715, 1¼-ton truck as its prime mover.

STATUS:

In production for US and various other governments. A towed version without radar is in production for the Belgian Air Force. See also AVADS (**2843.131**)

MANUFACTURERS:

THE UNION OF SOVIET SOCIALIST REPUBLICS

5543.131
23 mm ZSU-23-4 SP AA VEHICLE

DESCRIPTION:

This SP vehicle system consists of four 23 mm AA guns mounted on a common mounting, and fired together. The result is a useful volume of fire and a greatly increased chance of a hit over what would be achieved with four independent guns.

The vehicle provides low level cover for the armoured and mechanised divisions of the Soviet army, and is organic to the AA battalions of these divisions. The fire control radar will provide the lay for guns, and compute the target speed and height. It is not known how the target is first acquired, nor how much ammunition is carried.

The hull and automotive components are the same as the PT-76 tank, the differences being in the superstructure and turret.

CHARACTERISTICS:

Estimated total weight: 15,000 kg

All main dimensions similar to PT76 tank:

Estimated height: 2.2 m

Guns: 23 mm automatic cannon

Range—anti-aircraft role: 1,200 m

Elevation: 0° to 85°

Traverse: 360°

Rate of fire—each gun: 1,000 r.p.m.

Total: 4,000 r.p.m.

STATUS:

In service.

COUNTRIES SUPPLIED:

Warsaw Pact.

PORTABLE ANTI-AIRCRAFT GUIDED MISSILE SYSTEMS

SWEDEN

2348.131
RBS 70 ANTI-AIRCRAFT MISSILE SYSTEM
DESCRIPTION:

RBS 70 is a portable surface-to-air missile system operating on the optical beam-riding principle – which gives it substantial immunity to jamming. It is suitable for use against both fighter-bombers and helicopters, has a range of about 5 km and can be operated by one man – but for continuous firing a second man is needed.

The system is suitable for integration with other surface-to-air weapons or as a separate unit. Unlike many other portable anti-aircraft missile systems, RBS 70 can utilise precision target information from a search radar, and it is both possible and desirable to group several RBS 70 units with one or more search radars to form an anti-aircraft battery. RBS 70 is also designed to utilise IFF signals.

Three packs – stand, sight and missile in container – make up the complete firing unit which can be assembled and ready to fire in less than 30 seconds. The stand has three legs and forms the suspension device for the telescopic sight which has gyro-stabilised optics and which also contains the guidance beam transmitter.

To slew on to the target the operator uses coarse aiming, turning the whole sight housing in the required direction. For tracking, a thumb lever is used to operate the gyro-stabilised optics.

The missile is launched from a container which also serves for both storage and transport, the missile never being removed from the container except at the moment of firing. A starting motor ejects the missile from this launch container and separates from it at the mouth of the tube after which the missile sustainer takes over. The missile carries a receiver for the guide beam signals and a small computer to process them. The warhead has both proximity and percussion fuses but if desired the active optical proximity fuse can be paralysed before the missile is fired.

Among the items of test and training equipment supplied for use with the missile is a sight simulator for use in training operators.

CHARACTERISTICS:
Type: Man-portable surface-to-air guided missile system
Guidance: Optical beam riding on laser beam
Propulsion: Booster plus solid propellant sustainer
Warhead: High explosive with impact and proximity fuses

RBS-70 AA Weapon System

Weights:
Firing unit complete – about 80 kg
Missile in container – 22 kg
Container length: 1.6 m
Container diameter: 15 cm
Missile range: 5 km

STATUS:
Development started in 1969. Three series of firing trials have been held and development will be complete this year. Series production is planned to start in 1975.

MANUFACTURER:
AB Bofors, S-690 20 Bofors, Sweden.

THE UNITED KINGDOM

2409.131
BLOWPIPE PORTABLE ANTI-AIRCRAFT MISSILE SYSTEM

DESCRIPTION:
Blowpipe has been conceived primarily as a surface-to-air weapon for unit self defence in forward areas against close-range low-level air attack. In order to carry out this role effectively the equipment is compact, light and simple so that it can be both carried and operated by one man.

The weapon is suitable for use in world-wide extremes of climate with no maintenance needed during long periods in the field. It can be brought into action very rapidly, and reloading time is a few seconds. Blowpipe can be used against both attacking and receding fast aircraft and helicopter targets.

The Blowpipe weapon system is entirely self-contained with no external power requirements, and consists of two main components: the missile, sealed within its launching canister, and the aiming unit. The missile/canister combination is treated as a round of ammunition that can be taken out of store and fired with no preparation or testing. The aiming unit houses all the necessary equipment and controls to launch the missile and guide it towards the target.

CHARACTERISTICS:
Type: Man-portable, shoulder-fired surface-to-air (or surface) tactical guided missile
Guidance Principle: Radio command with optical tracking
Guidance Method: Twist and steer by nose-mounted control surfaces
Propulsion: Two-stage booster-accelerator solid-propellant rocket motor
Warhead: High-explosive with proximity fuse
Missile Length: 1.4 metres
Missile Diameter: 76 mm
System Weight: 18 kg with one missile

OPERATION:
To prepare the system for action all that is necessary is to clip the aiming unit to the canister, which only requires a few seconds, and the complete system, which weighs less than 40 lbs (18 kg), is lifted to the man's shoulder. The aimer acquires his target in his monocular sight, fires the missile and controls its flight to the target by means of a thumb-operated flight controller.

The act of pulling the trigger activates thermal batteries for power supplies in both the missile and canister (to supply the aiming unit). When these batteries have reached a sufficiently high voltage (in about 1 sec), the missile first stage motor ejects the missile from the canister. This motor is extinguished before the missile fully emerges and the missile coasts for a safe distance from the aimer before the second stage main motor ignites to boost the missile to supersonic speed.

The missile is fitted with flares which in the early stages of flight are detected by a sensor in the Aiming Unit to gather the missile to the centre of the aimer's field of view. From then on the aimer guides the missile to the target by means of the controller with up/down and left/right movements.

On arrival in the vicinity of the target a proximity fuse in the nose of the missile detonates the warhead.

Commands are transmitted to the missile over a radio link. Reception aerials in the missile pass these commands through the receiver and decoder to the missile control system. This works on "twist and steer" principles with one pair of nose mounted control surfaces working differentially to produce roll, and the other pair producing lateral movements.

British Army firing of Blowpipe missile

Blowpipe is fitted with a fully integrated identification (IFF) system which prevents friendly aircraft from being inadvertently engaged as a result of incorrect visual identification.

The missile has a slim, cylindrical body and ogival-nose cone. Cruciform delta-shape canard control surfaces are mounted on the nose cone and a unique type of cruciform delta-shape tail-fin assembly is used. This consists of a sliding ring structure which, in the launching canister, is positioned near the nose of the missile, enabling the diameter of the rear of the canister to be minimised. As the missile is launched, it passes through the tail-fin assembly which finally locks on the rear of the missile. The folded wing tips open to their full span as they emerge from the canister.

DEVELOPMENT HISTORY:
During 1966 the Royal Radar Establishment conducted feasibility studies with three contractors to investigate the design of a system to meet the requirements of the Naval and General Staff target for a man-portable all arms weapon for self-defence against low flying aircraft and surface targets. Following a complete analysis of the three competing proposals, the RRE recommendation was for a guided weapon system based on a private venture being pursued by Short Bros & Harland Ltd which had resulted in a test vehicle which they had christened "Blowpipe".

The feasibility study was succeeded by a one year project study for the complete weapon system, comprising contracts placed with all the participating contractors.

Close-up showing missile in its launcher

STATUS:
In production for the British Army the Royal Marines and the Canadian Armed Forces.

MANUFACTURERS:
The following manufacturers are known to have been associated with the development and manufacture of the system.
Main contractor: Short Bros & Harland Ltd, Belfast.
IFF System: Cossor Electronics Ltd.
Fuse: Marconi Space and Defence Systems Ltd.
Ignition, safety and arming unit: Royal Ordnance Factory, Blackburn.
Firing circuits: Pye Dynamics Ltd.
Thermal Batteries: Mine Safety Appliances Ltd.
The co-ordinating research and development authority is the Royal Radar Establishment.

2841.131
ALTERNATE STINGER

DESCRIPTION:

Alternate Stinger is the rather unhappy title bestowed upon a projected portable anti-aircraft missile development aimed at producing a competitor in the US military market for the General Dynamics Stinger missile (**2805.131**).

The new development is understood to have been entrusted to Philco-Ford who are to produce 18 prototype and qualification models of the missile on a $5.2 million contract from the US Army Missile Command. It is further understood that the USAMC hopes to decide during the course of 1975 which of the two competing missiles it will adopt.

The principal known difference between the two missiles is in their guidance systems. Stinger utilises passive infra-red homing, the Philco-Ford missile will be guided by the reflected energy of a laser beam trained by the gunner on the target.

STATUS:

Development.

MANUFACTURER

Aeronutronic Division, Philco-Ford Corporation, Newport Beach, California 92063.

2784.131
REDEYE PORTABLE ANTI-AIRCRAFT MISSILE

DESCRIPTION:

Redeye is a shoulder-fired guided missile system designed to give a soldier an effective defence against low-flying aircraft. The missile's infra-red sensing device homes on the heat of an aircraft's engines. The Redeye carries a high-explosive conventional warhead and has a two-stage solid-propellant engine. The light launching tube is also a carrying case and can be borne through brush and over rough terrain. A shipping and storage container holds one missile and three battery / coolant units.

On sighting a hostile aircraft, the gunner tracks it in an optical sight. At the same time, he energises the missile guidance system. A buzzer located in the launch tube gripstock informs the gunner when the missile is ready to fire. Upon firing, the booster charge propels the missile out of the launch tube. When the missile has cleared the launch tube muzzle by a distance sufficient to protect the gunner from blast effect (about 6 m), the main rocket ignites and propels the missile the rest of the way to its target. The missile is stabilised in flight by cruciform tail fins and steered by two movable fins close to its nose.

CHARACTERISTICS:

Designation: MIM-43A
Type: Man-portable, shoulder fired, surface-to-air guided missile
Guidance: Optical aiming. Infra red homing
Propulsion: Solid-propellant booster and sustainer
Warhead: High-explosive
Missile Length: 1.22 metres
Diameter: 70 mm
Weight: 13 kg
Speed: Supersonic
Range: Not disclosed. Probably about 3 km
Crew: Normally two

TEST AND TRAINING EQUIPMENT:

Guided Missile Test Set AN / TSM-82 is provided for use at depots and ammunition supply points.

Guided Missile Training Set M76 simulates full launch procedure and enables an instructor to check correct gunner operation.

Field Handling Trainer M46 is for handling and sighting practice only.

Moving Target Simulator M87 gives full practice to gunner.

DEVELOPMENT HISTORY:

Development began in 1959 after a feasibility study in the previous year. An initial production contract was announced in 1964 and many thousands of the weapons have now been made. Extended trials have been carried out successfully both in tropical areas and in "forty-below" conditions in Alaska.

STATUS:

Redeye is employed in the forward battle area to protect combat troops against low-level aircraft. In the US Army the weapon is issued to Redeye teams, each made up of a gunner and assistant gunner. From four to six of these teams are assigned to a Redeye section at infantry battalion level.

Procurement of Redeye was completed in Fiscal Year 1970. It is used by the USMC as well as the US Army and has been supplied also to the Australian and Swedish armed forces.

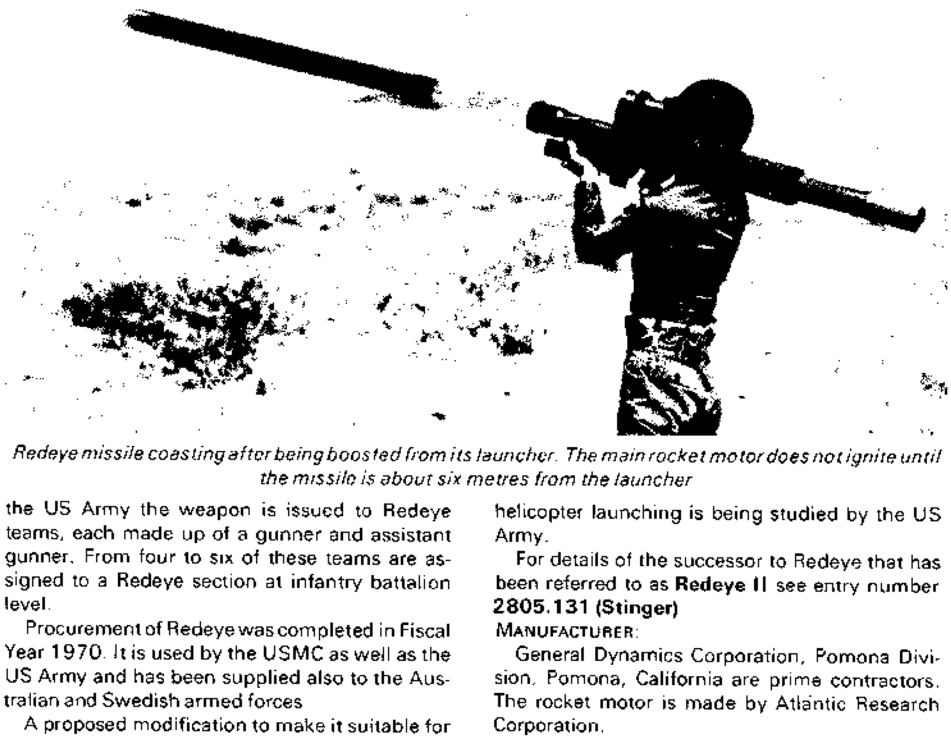
A proposed modification to make it suitable for helicopter launching is being studied by the US Army.

For details of the successor to Redeye that has been referred to as **Redeye II** see entry number **2805.131 (Stinger)**

MANUFACTURER:

General Dynamics Corporation, Pomona Division, Pomona, California are prime contractors. The rocket motor is made by Atlantic Research Corporation.

A gunner being instructed in the use of the Redeye weapon (US Army photograph)



Redeye missile coasting after being boosted from its launcher. The main rocket motor does not ignite until the missile is about six metres from the launcher

2805.131
STINGER PORTABLE ANTI-AIRCRAFT MISSILE – XFIM-92A

DESCRIPTION:

Previously known as Redeye II, Stinger will be Redeye's successor and has been under development for about four years as part of the US Army's Manportable Air Defense System (MANPADS).

In announcing the new name, the Army said that Stinger would incorporate a high-performance propulsion system, improved infra-red devices and an advanced guidance technique which will give the weapon a greater range and velocity.

As so far developed, Stinger is a slightly larger weapon than Redeye: its overall length of some 152 cm is about 20% greater than that of Redeye and it weighs about 6% more – about 13.4 kg.

Stinger also uses passive infra-red homing; but its sensor works at a considerably shorter wavelength (4.1-4.4 microns) than Redeye and can thus home on the relatively high intensity exhaust plume of an aircraft engine.

In parallel with the original development programme which is still continuing the US Army Missile Command's Stinger Project Office is implementing a programme known as **Stingthrift** aimed at reducing the manufacturing cost of the weapon without sacrificing Army performance requirements. The USAMC office is working closely with General Dynamics on this exercise.

STATUS:

Development. In 1973 laboratory and range tests of elements of the system were carried out. In January 1974 the first guided test was successfully carried out: the test vehicle, fired from a fixed platform scored a direct hit on a target drone.

Reference should also be made to the competing project known as Alternate Stinger **(2841.131)**.

MANUFACTURER:

System contractor: General Dynamics Corporation, Pomona Division, Pomona, California.

Stinger AA missile system

THE UNION OF SOVIET SOCIALIST REPUBLICS

2941.131

SA-7 (GRAIL) MAN-PORTABLE ANTI-AIRCRAFT MISSILE

DESCRIPTION:

During the later stages of the war in Vietnam it was found that North Vietnamese forces were using a shoulder-launched man-portable anti-aircraft missile system similar in general principle to the American Redeye missile **(2784.131)** or the British Blowpipe **(2375.131)**.

These missiles were found to be of Russian design and manufacture and it was said that the missile's Russian name was Strela ("arrow") but this has not since been confirmed. The missile is now known as SA-7 in the US alphanumeric code, however, and its NATO code-name is believed to be Grail.

During 1973 it was reported that BRDM-2 vehicles **(5036.102)** had been seen equipped with multiple SA-7 launchers: vehicle-mounted multiple launchers were also encountered during the 1973 Arab Israeli war.

Information on the weapon system is still in short supply but it appears that the missile is about 125 cm long, about 7 cm in diameter, has a range of about 3,500 metres, can engage targets at heights between 50 and 1,500 metres, has a passive infra-red homing guidance system and carries a high-explosive warhead. Sighting seems to be simpler than it is on its Western equivalents.

STATUS:

Operational. It is not known when the weapon was first introduced but, in addition to its use in Vietnam and Egypt it is known also to have been used by rebel forces in Angola – in its shoulder-fired role.

SA-7 anti-aircraft missile system

SHIPBORNE SURFACE TO AIR WEAPONS

CANADA

2036.231
CANADIAN SEA SPARROW MISSILE SYSTEM

DESCRIPTION:

This shipborne missile system which is intended for use in both surface-to-surface and surface-to-air engagements, has been developed for the Canadian Government by Raytheon Canada working in close collaboration with N.V. Hollandse Signaalapparaten in the Netherlands, the latter having been responsible for the fire control system.

The system comprises four sub-systems – the Sparrow III missile, a Guided Missile Launching System (GMLS) a Gun/Missile Fire Control System (GMFCS) and a Control and Interface Group. There are two standard installations – a single installation forward giving an arc of fire that lies mainly in the forward direction (about 190 degrees) and a dual port/starboard installation that gives all-round coverage. In the dual installation the GMLS and GMFCS are duplicated and cross-linked to provide maximum operational flexibility.

Basic weapon of the system, the AIM-7E2 version of the Sparrow III missile (**1106.331**), is in operational use in other systems in various countries. In the GMLS it is carried on a four-missile support pylon (**2714.293**) on an extendible cantilever beam. The launcher head rotates automatically about horizontal and vertical axes under the control of the GMFCS. Missiles can be fired singly or in rapid succession, automatic pre-launch commands being supplied to the missile electrically. Semi-automatic power loading provides rapid recycling and launching of missiles from each launcher.

The Signaal M22/6 GMFCS (**1359.281**) provides simultaneous early warning, air target tracking and surface target tracking and can control both the missiles and the ship's guns in simultaneous operation against air and surface targets. Electronically of compact solid-state design, it comprises a fire-control radar, an emergency back-up optical sight and a combined display, control and computer unit. Both optical sight and radar aerial systems are fully stabilised.

The radar (**1590.253**), which can track air and surface targets simultaneously, features monopulse air tracking track-while-scan facilities, MTI search, pulse-doppler tracking, extensive ECCM facilities and a missile guidance capability, a digital computer for system control tracking and weapon prediction. Search radar data are presented on a PPI, air tracking data on an A-scope and surface tracking and splash spotting data on a B-scope.

In the Control and Interface Unit, radar and other input data is processed to determine target status and future position; and information thus generated is passed to the ship's tactical data system, to the GMFCS as target designations and to the GMLS and missiles as pre-launch and steering commands. The sub-system also provides for missile status checking and for control of the missile pre-flight warm-up.

Three operators are required to man a single installation and only four for a dual installation. All-up weight of a dual installation, including missiles, is about 37,000 kg.

STATUS:

The four DDH 280, "Iroquois" Class destroyers of the Canadian Armed Forces have been fitted and following initial trials in 1973, the four ships are carrying out full firing sea trials during 1974. The two replenishment ships, *Preserver* and *Protector*, have simpler Canadian Sea Sparrow installations which employ a single launcher.

MANUFACTURERS:

System generally – Raytheon Canada Ltd, Waterloo, Ontario, Canada.

Fire Control System – N.V. Hollandse Signaalapparaten, Hengelo (O.), Netherlands.

FRANCE

2114.231
CATULLE SURFACE-TO-AIR WEAPON SYSTEM

DESCRIPTION:

Catulle is the name given to a naval version of the Javelot land-mobile weapon system (**2110.131**) and is a controlled-dispersion multiple rocket system which fires salvoes of 40 mm projectiles with proximity fuses from a 96-tube launcher.

Intended for defence against low-flying aircraft or cruise missiles, Catulle would complement existing shipborne weapon systems and would help to fill the gaps that exist between rapid-fire anti-aircraft guns and surface-to-air guided missiles. The concept is indeed not unlike that of the American Vulcan/Phalanx system (**2543.231**) but the method of realisation is different.

STATUS:

System study on behalf of the French Navy. Apparent lack of activity over a considerable period suggests that this project may have been overtaken by events and allowed to lapse.

MANUFACTURERS:

Thomson-CSF, 1 rue des Mathurins, 92222-Bagneux.

2122.231
HIRONDELLE SURFACE-TO-AIR WEAPON SYSTEMS

DESCRIPTION:

Based on the Matra Super 530 air-to-air missile (**1349.331**), the Hirondelle surface-to-air missile system is intended especially for naval use and particularly on small fighting ships such as the fast patrol boat *La Combattante II*.

Mounted on such a vessel, a multi-missile launcher (typically 4-chambered) would provide a measure of short-range protection against very low-altitude attacks by aircraft or cruise missiles. The Super 530 missile has an X-band semi-active radar homing head which would be used in conjunction with a tracking radar on the ship. The proposed missile launcher is trainable and would be remotely-controlled.

See also entry (**1353.231**) in the Naval Fire Control and Action Data Automation section.

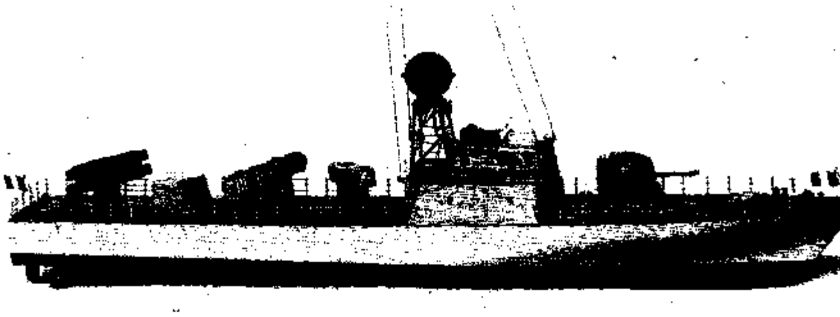
STATUS:

Project. The missile is due to become operational in 1977. No details of Hirondelle installations have been obtained.

MANUFACTURER:

System: Electronique Marcel Dassault, 55 Quai Carnot, 92-St Cloud, France.

Missile: Engins Matra, Avenue Louis-Breguet, 78 Velizy Villacoublay, France.



Model showing Hirondelle system (aft) fitted to a Combattante II*-class fast patrol boat*

1177.231
MASURCA SURFACE-TO-AIR MISSILE SYSTEM

DESCRIPTION:

Masurca is the name given to a surface-to-air missile system which forms the main anti-aircraft armament of the French frigates *Duquesne* and *Suffren*, whose principal role is that of escort to the aircraft carriers *Foch* and *Clemenceau*. Masurca also has armed the AA Cruiser *Colbert* since 1973 when her modernization was completed. Each of the Masurca ships is equipped with an elaborate and comprehensive three-dimensional surveillance radar, two independent Fire Control Systems and a twin launcher. Supersonic targets can be intercepted at ranges of 40 km or more.

The main characteristics of the missile are length (with booster) 8.6 m, (without booster) 5.29 m, diameter 41 cm, span of booster fins 150 cm, weight (with booster) 1,850 kg, (without booster) 840 kg. A proximity-fused high-explosive warhead is carried, and both boosters and sustainer motors are solid-fuel units.

Two types of guidance system are employed: the Mk 2 Mod 2 uses radio command, and the Mk 2 Mod 3 is equipped with a semi-active radar homing head. Externally the two versions are virtually identical, and the ship installation is designed to handle mixed salvoes of the two types simultaneously.

In addition to the missiles themselves, the Masurca weapon system contains the following main elements.

(1) A missile twin launcher
(2) Two storage and handling equipments
(3) Two remote-control directors, each linked with a tracking radar for radio command missiles and a target illuminator radar for the homing version
(4) Two test equipments for checking missiles

The DRBR 51 tracking radar has three main functions:

(1) Whichever type of missile is used, it continuously follows the target.
(2) In the case of the homing version (Mk 2 Mod 3), it controls the painting of the target illuminator radar.
(3) In the case of the radio command version (Mk 2 Mod 2), it measures missile displacement from the line of sight to the target.

OPERATION:

Radio Command Missile: A two-axis director is slaved to the DRBR 51 scanners and a TV camera, and is used for the initial alignment of the latter in the direction of the target, following target designation by the DRBI 23. The DRBR 51 has three aerials, the main one of which is used for tracking the target and measuring angular displacement of the missile relative to the line of sight to the target. (This unit is also used for target illumination when firing the homing Mk 2 Mod 3 Masurca). The second aerial is a wide-angled, broad-beam unit which is used for gathering the missile after launch, and the third is also a broad-beam system which illuminates radio command missiles during their gathering phase and is used for the transmission of command signals.

Command signals for the missiles are transmitted in the 7 cm waveband, and can provide guidance signals for two missiles simultaneously. There are two 5 cm radar tracking channels, 'Blue' and 'Yellow', one for each missile, and each radio command missile is equipped with a 5 cm transponder to increase long-range performance.

Semi-active Radar Homing Missile: Target pointing of the director and launcher ramp is similar to that for the launching of radio command missiles. The DRBR 51 main aerial operates as an X-band target illuminator radar. The missile is equipped with two aerial systems, one at the front of the vehicle, and twin horns at the rear. The latter are used to receive the illuminating radar signals direct, to provide a reference signal which can be compared with the signals reflected from the target that are collected by the forward missile aerial. This enables a doppler component to be extracted, which is used in the on-board computation of a proportional navigation interception course to the target.

DEVELOPMENT:

Development of the Musurca missile has been the responsibility of the French Naval Arsenal "Etablissement des Constructions et Armes Navales de Ruelle". The Engins Matra firm has been cooperating with the "ecan de ruelle" in completing the development and meeting the required production programme of the homing version.

Fire control radars, missile homing head and proximity fuse, have been developed by Thomson-CSF and fire control system computer by IBM France. The launching, storage and handling equipments have been designed and developed by the "Etablissement des Constructions et Armes Navales de Ruelle".

2111.231
NAVAL CROTALE SURFACE-TO-AIR WEAPON SYSTEM

DESCRIPTION:

Formerly known as Murène in the Murène/Mureca system, Naval Crotale is a proposal for a relatively straightforward adaptation of the land-mobile Crotale weapon system (**2074.131**) for naval use.

Full details of the most recent proposals have not been made available, but it appears that the intention is to mount the weapon system firing unit (launcher turret and monopulse tracking radar) in much the same way as it is mounted on its vehicle in the land-based version but with certain mechanical differences appropriate to a shipborne structure. The complete structure, however, would be roll-stabilised.

Surveillance and target designation functions would be performed by the ship's radars instead of by a separate track-while-scan radar as in the land-mobile system. The only other likely difference of any consequence between the two systems is the probable provision of a reloading facility.

STATUS:

Not definitely known. It seems that there is a definite requirement for a system of this type; but a strong competitor for a French contract in this area must be the naval version of Roland II (**2217.231**) and any contract is quite likely to be awarded on the strength of the results of a competitive evaluation of the two systems in their land-mobile form. Based solely on published promotional material, it appears that Marine Roland II is the preferred candidate.

MANUFACTURERS:

System: Thomson-CSF, Division Systèmes Electronique, 1, rue des Mathurins, 92222-Bagneux, France.

Missile: Engins Matra, Départment Missiles, Avenue Louis-Breguet, 78-Velizy, Villacoublay, France.

INTERNATIONAL

2217.231
MARINE ROLLAND II SHIPBORNE SURFACE-TO-AIR WEAPON SYSTEM

DESCRIPTION:

The shipborne Roland II M is a proposal based on a 'packaged' version of the all-weather variant of the tank-mounted land-mobile Roland weapon system (2218.131). Since its introduction in the early 1970s, it has undergone a series of changes of configuration, evidenced by the variations in drawings and models made public at successive exhibitions. The latest of these configurations is shown in the accompanying photographs of a cut-away model of a self-contained Roland II M system for shipboard installation. This arrangement suggests a completely autonomous system within a single unit comprising, launcher/radar assembly, magazine and reload system, and operators fire control console. All but radar and launcher are below deck.

STATUS:

The French Government is known to be interested in the Roland II M project but no details of programme status have been obtained.

MANUFACTURERS:

Aérospatiale, 92-Chatillon, France.

Messerschmitt-Bölkow-Blohm, Munich, Germany.

ITALY

2228.231
ALBATROS SURFACE-TO-AIR MISSILE SYSTEM

DESCRIPTION:

Albatros is an all-weather missile and gun shipborne weapon system designed for short-range air defence against aircraft and anti-ship missiles, including those flying at very low altitudes or having high angles of dive. The system can be installed in any type of vessel down to small escort units of some hundred tons displacement.

The complete weapon system includes the following major sub-systems:

—a missile and gun fire control system—a missile launching system and up to three groups of guns among which there may be two different ballistics.

—the Sparrow III (RIM-7H) or Aspide missiles.

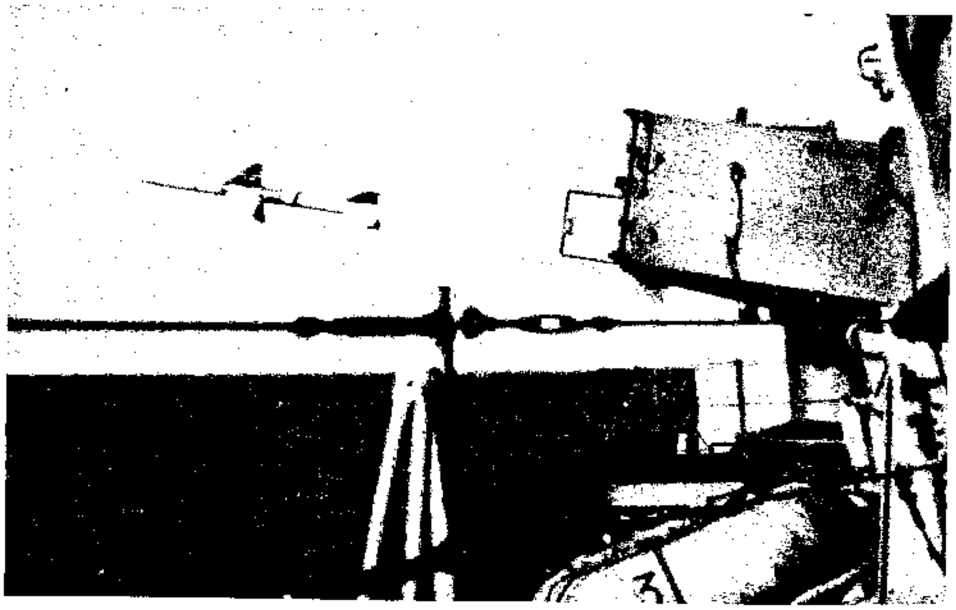
DESCRIPTION:

Details of this inter-relationship between these sub-systems and of the operation of the complete system can be found under entry number **1551.281** in the Naval Fire Control and Action Data Automation section.

STATUS:

Trials were carried out by the Italian Navy during 1973 off the Sardinia missile test range from the proving ship *Aviere* on which a prototype system was installed. The trials included launches against remote controlled air targets simulating anti-ship missiles; against surface targets; measurements of the system's ability to detect and counter air attacks under severe conditions; and checks of ECCM facilities.

A contract for the provision of about ten Albatros systems for installation on a number of major and medium-class ships of the Italian Navy was negotiated in 1973 with installations following in 1974.



Sparrow III missile launched from Albatros launcher in September 1972

MANUFACTURER:

Main contractor for the system: Selenia Industrie Elettroniche Associate SpA, via Tiburtina Km 12,4 Rome, Italy.

7022.231
SEA INDIGO SHIPBORNE ANTI-AIRCRAFT WEAPON SYSTEM

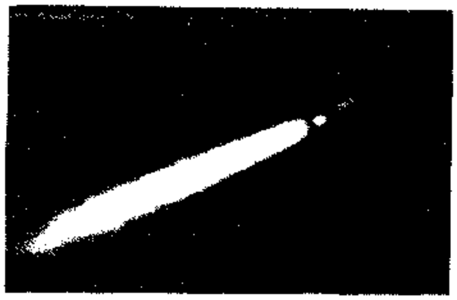
DESCRIPTION:

Sea Indigo is a shipborne version of the Indigo (**2235.131**) land-based surface-to-air tactical guided missile. The missile and its operational characteristics are substantially the same as those given in the entry for Indigo; the principal difference being the substitution of the Sea Hunter fire control system - also used for the surface-to-surface Sea Killer Mk 1 (**2240.221**) and Mk 2 (**2253.221**) missiles for the modified Super-Fledermaus fire control system.

For installations on naval craft of less than 500 tons displacement it is intended that manual reloading of the missile launcher shall be used. For installations on larger vessels automatic reloading is proposed; and one such installation, for both Sea Indigo and Sea Killer Mk 2 (Vulcano) missiles, is described elsewhere in this section (Combined Sea Indigo/Sea Killer Mk 2 Weapon System **2371.231**).

CHARACTERISTICS:

Type: Shipborne surface-to-air tactical guided missile

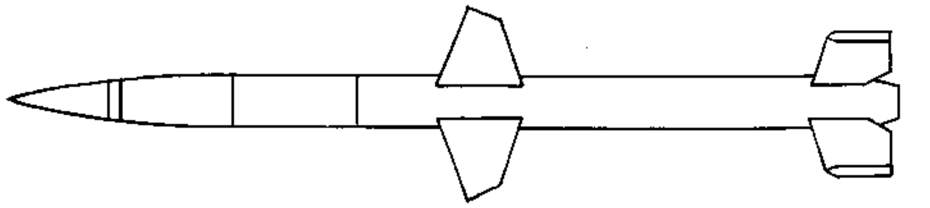


Sea Indigo missile in flight

Guidance Principle: Beam-riding with stand-by radio command guidance and infra-red tracking
Guidance Method: By control of movable cruciform control surfaces at centre of missile. Stabilisation by cruciform tail fins
Propulsion: Solid-propellant rocket motor. 3,800 kg st for 2.5 sec.
Warhead: High-explosive (21 kg) fragmentation type with infra-red proximity fuse
Missile Length: 3.32 metres
Missile Diameter: Body 19.5 cm. Span 86 cm
Launch Weight: Approx 121 kg
Speed: Approx Mach 2.5 at burn-out
Range: Approx 10 km slant range
Ceiling: Approx 6,000 metres

OPERATION:

The missile is armed with both direct action and proximity fuses, so that both direct hits and near misses are effective. It is launched from a quadruple missile launcher, and a simple arrangement is provided for reloading of missiles on board ship.



Sea Indigo

The primary method of guidance is beam riding combined with command signals from the Sea Hunter fire control system. A secondary method of guidance is provided for use in conditions of radar jamming or interference, using an infra-red camera on the aerial mounting. All necessary equipment is engineered in combination with the Sea Hunter system, the missile checkout and fire guidance controls being centralised in the missile control console.

DEVELOPMENT:

Development was initiated by Contraves Italiana SpA in 1963 following hard on the heels of the development of the land-based Indigo missile. The first prototype was completed in 1964.

Sistel SpA took over the project from Contraves in 1969.

MANUFACTURERS:

Sistel SpA Via Tiburtina 1210, 00136 Rome. Other manufacturers as for Indigo.

THE UNITED KINGDOM

1019.231
SEACAT SHIPBORNE SURFACE-TO-AIR MISSILE

DESCRIPTION:

Seacat is a close range, shipborne, guided missile system for anti-aircraft defence which may also be used against surface targets within visual range. The system has been designed to provide a simple and low-cost anti-aircraft capability, and represents a very cost-effective system. The guidance system is based on the use of optical tracking and a radio command link, but the system is capable of various degrees of sophistication and this has in fact been undertaken in a number of instances. Generally, such improvements take the form of integrating Seacat with ships' fire control systems. An advantage of this is that disablement of the fire control radars, or other part of that system, still leaves the option of the optically guided mode.

OPERATION:

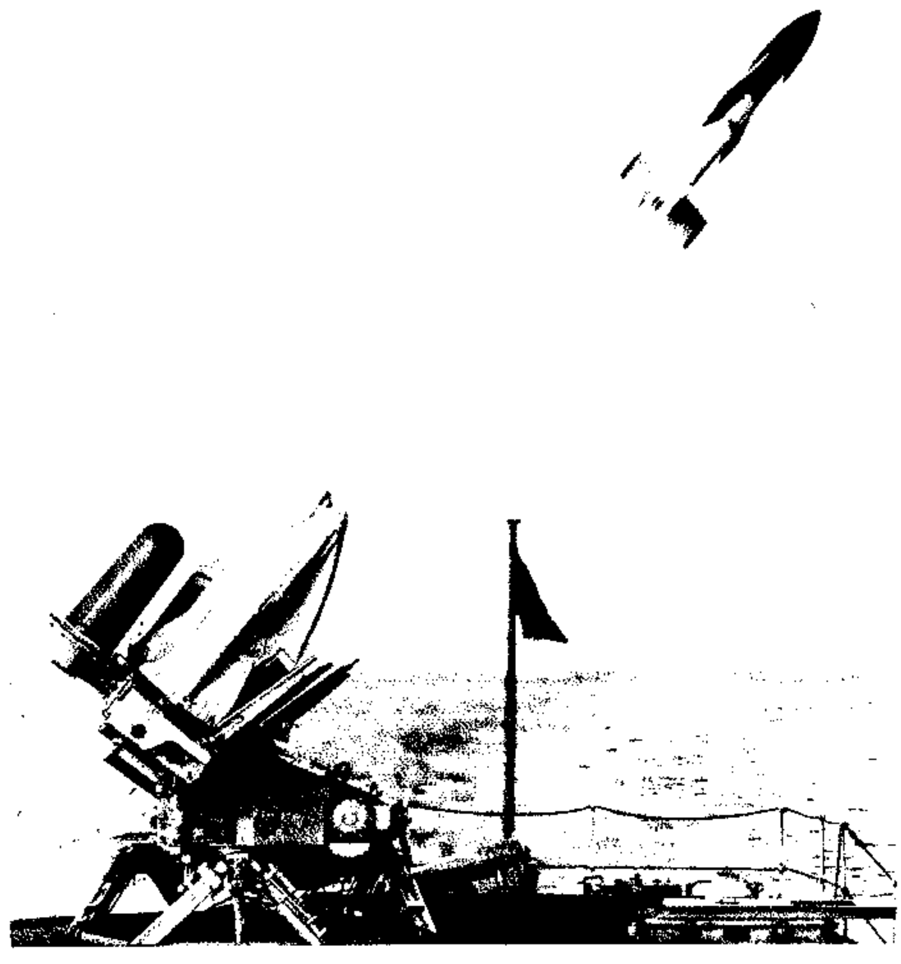
The basic form of the system, introduced into the Royal Navy as Guided Weapons System Mk 20 (GWS 20), consists of separate launcher and operator mounts, the latter carrying sighting binoculars with which the aimer first 'gathers' the missile after launch and subsequently tracks it to the target. A thumb joy-stick control is provided for missile guidance. Movements of the joystick are converted into command signals which are transmitted to the missile from a unit on the launcher mounting to maintain the missile on the line of sight to the target.

Seacat has since been deployed with the RN GWS 22 (**1242.281** and **1563.253**) fire control system in which a lock and follow tracking radar is linked to the aimer's binocular sight. Subsequent operation is the same as for the GWS 20 system. It has also been combined with Contraves Sea Hunter, San Giorgio NA9, and Signaal M 40 series fire control systems. A later development is a system that replaces the optical sighting binocular with a CCTV (Closed Circuit Television) system produced by Marconi-Elliott Avionic Systems as the 323 Series (**1021.293**). This enables the aimer to be placed in a much less vulnerable position and also results in important improvements in efficiency. The missile gathering phase has been reduced from about 7 seconds (conventional optical technique) to 6 seconds or less with the aid of CCTV.

Seacat, under the Swedish designation RbO7, is used with the Hollandse/Signaalapparaten M4-1 fire control system.

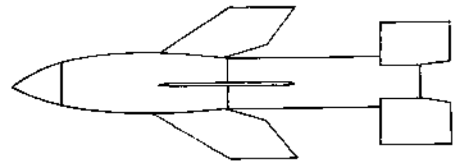
A lightweight version of Seacat has been developed for installation in such vessels as 30-metre fast patrol boats and inshore mine-sweepers, giving them guided-weapon defence against low-flying aircraft. It is in service with the Imperial Iranian Navy, and has attracted interest from other navies, some of which already have the standard Seacat system.

It employs a new three-round launcher (based on the Short Tigercat launcher) which weighs only 2,007 kg with all its ancillaries instead of the 4,700 kg of the standard four-round Mk 20

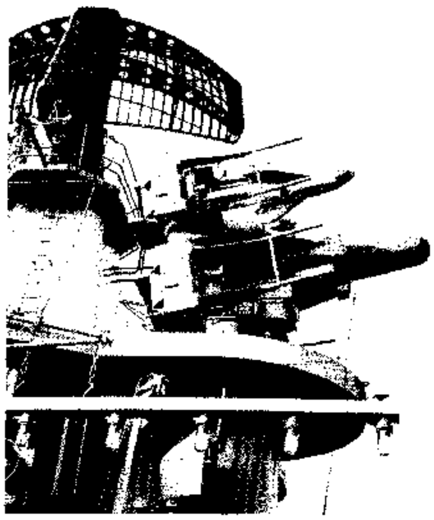


Seacat launch from the three-round launcher of the lightweight system

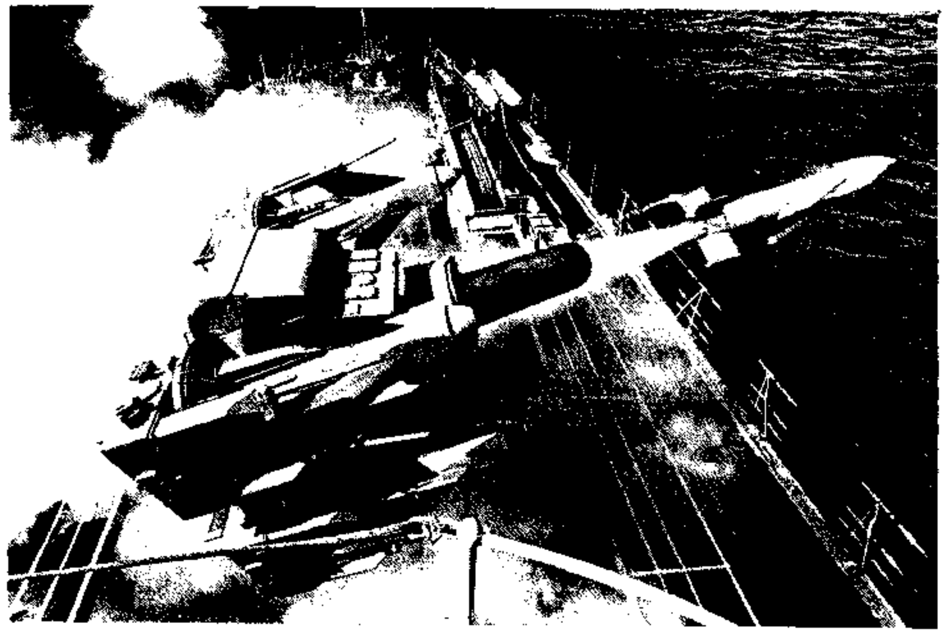
Close-up of the Seacat visual director



Seacat



Standard 4-round Seacat launcher on a Royal Netherlands Navy Ship



Seacat launch from the standard four-round launcher

launcher. Binoculars mounted on the head of a single manually operated pedestal director form a combined director and missile aiming sight.

MAIN CHARACTERISTICS:

Maximum effective range approx 4,750 metres. Warhead – high explosive. Solid fuel motor. Length 1.48 m, max span 65 cm, estimated weight 63 kg.

DEVELOPMENT:

Development work started in the late 1950s and the first sea trials took place on HMS *Decoy* in 1962. The basic system has proved itself adaptable to other roles and a land-based version has been developed as the Tigercat (**2465.131**).

STATUS:

In addition to the RN, Seacat has been ordered by 14 other navies: Argentina, Australia, Brazil, Chile, West Germany, India, Iran, Malaysia, Netherlands, New Zealand, Sweden, Libya, Thailand, and Venezuela.

MANUFACTURERS:

Short Brothers & Harland Ltd, Castle-reagh, Belfast BT6 9HN, Northern Ireland.

6004.231
SEA DART SURFACE-TO-AIR MISSILE

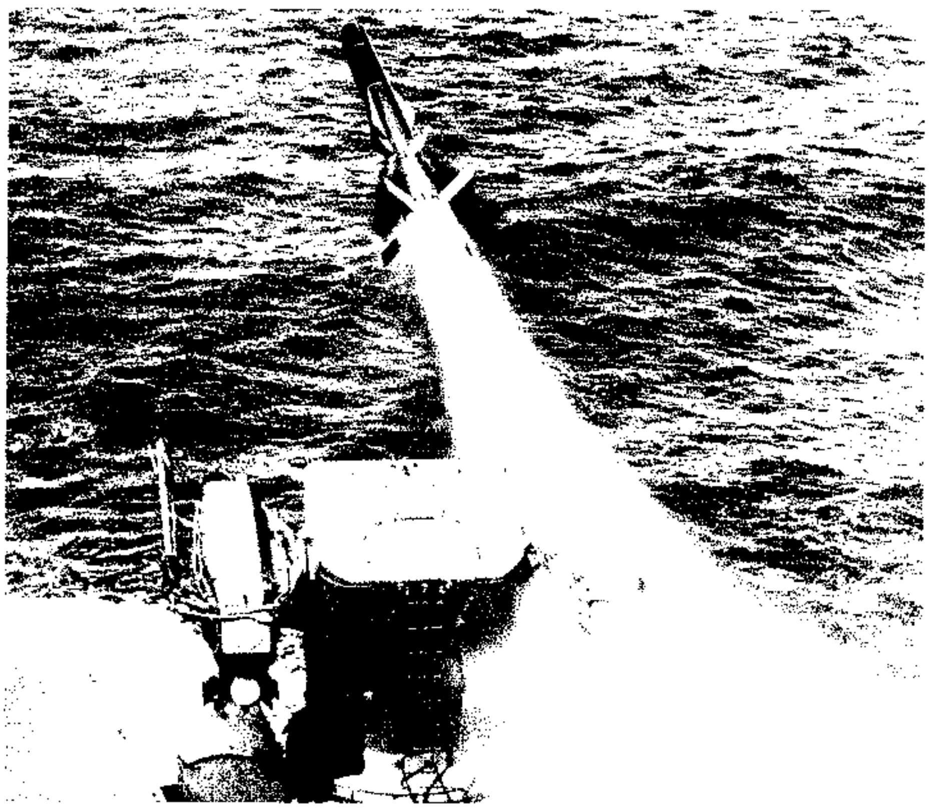
DESCRIPTION:

Sea Dart is a third-generation area defence weapon system, capable of intercepting aircraft, at both very high and extremely low altitudes, and air and surface launched missiles. It is also effective against surface vessels. Launch rate is rapid and the weapon system is capable of dealing simultaneously with many targets. Despite all this the system can be installed in a variety of fighting ships from small frigates upwards – including some vessels that would be too small to accept, for example, Seaslug (**6003.231**).

The missile is launched from a twin launcher. Performance data are classified and only the linear dimensions have been released for publication: other data in the accompanying table are taken from published unofficial estimates.

The missile is virtually a thick walled cylinder built around the Rolls-Royce (1971) Ltd. Odin ramjet engine. The guidance equipment (Marconi Space and Defence Systems), the proximity fuse (EMI), the control system (Sperry Gyroscope division of Sperry Rand Ltd.) and the fuel tanks and engine controls are all wrapped around the cylinder.

The guidance system is one of a semi-active 'homing all the way' nature. It uses a proportional navigation law which can be changed during flight. The ramjet engine enables the missile to fly at controlled speeds throughout its flight envelope. The guidance system will detect very small changes in target movement. This capability combined with very fast control responses enables very small miss distances to be achieved.



Sea Dart leaving twin launcher during trials

CHARACTERISTICS:

Designation: CF299

Type: Shipborne area defence, surface-to-air, surface-to-surface and anti-missile guided weapon system

Guidance Principle: Radar guidance and semi-active homing using Tracker Illuminator Radar type 909

Guidance Method: By control of movable tail surfaces

Propulsion: Solid-propellant booster and ramjet sustainer

Warhead: Presumably high-explosive

Length: 4.36 m

Body Diameter: 42 cm

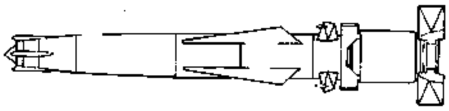
Span: 91 cm

Launch Weight: 550 kg

Range: At least 30 km

OPERATION:

Fully automatic magazine handling and loading arrangements. Mssiles are stowed vertically in magazine and are hoisted through an intermediate-stage to the electrically driven twin launcher. Targets are designated to the system in



Sea Dart

three co-ordinates by radar. The system automatically tracks the target and points the launcher. Radar illuminates the target to provide the missile with the RF signal for self guidance onto the target. The Type 909 target tracking and illuminating radar (**1559.253**) produced by Marconi Radar Systems has been developed from the equipment used with certain Bloodhound and Thunderbird missile systems. The missile is boosted to speed by a solid fuel tandem boost and speed is sustained by an Odin ram jet burning a liquid fuel.

DEVELOPMENT.

Development started August 1962. Test firings began in 1965 and the first production order was announced in November 1967.

STATUS

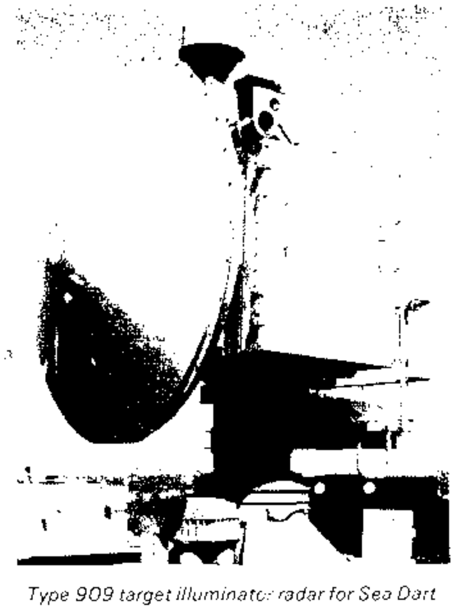
Development is complete and the first system is at sea in HMS Bristol. HMS Sheffield, the first of six Type 42 destroyers ordered by the Royal Navy, will be in operation in 1974. Sea Dart will also be installed in the two Type 42 destroyers ordered by the Armada Republica Argentina, and will provide area defence for HMS Invincible, the first through deck cruiser at present being built for the Royal Navy.

MANUFACTURERS:

System contractor is Hawker Siddeley Dynamics Ltd., Manor Road, Hatfield, Herts, AL10 9LL, England. Other contractors associated with the system include:

Marconi Space and Defence Systems Ltd. – Guidance: Rolls Royce (1971) Ltd. – Odin Ramjet: Sperry Gyroscope division of Sperry Rand Ltd. – Missile Control. EMI – Fuse: Vickers Engineering Ltd. – Launcher Magazine and Handling Equipment. Marconi Radar Systems, Ltd. – Type 909 Tracker Illuminator Radar: Ferranti Ltd. – Computer and Data Handling: Plessey Radar Ltd. – Operations Room Equipment.

Sea Dart launch



Type 909 target illuminator radar for Sea Dart

6003.231
SEASLUG SURFACE-TO-AIR MISSILE

DESCRIPTION.

Seaslug is a long-range beam-riding shipborne surface-to-air guided missile system.

Targets are detected at long range by radar (3-D or surveillance plus heightfinder) and their coordinates are supplied to the missile system control which commands the launcher. A twin ramp launcher is used and is reloaded from a between-decks magazine.

There are two versions of the missile, the Mark 2 having a rather longer range and better performance against low-flying aircraft. Both missiles have a surface-to-surface capability, but again that of the Mark 2 is better than that of the Mark 1.

CHARACTERISTICS.

Type: Shipborne surface-to-air tactical guided missile
Surface-to-surface capability

Guidance Principle: Beam-riding using type 901 M shipborne radar with coded transmissions

Guidance Method: By control of tail surfaces

Propulsion: Solid-propellant sustainer with four wrap-around solid-propellant boosters

Warhead: High-explosive with proximity fuse

Missile Length: 6 metres

Missile Diameter: 41 cm

Range: Probably better than 45 km. Targets engaged at heights above 15,000 metres in trials

OPERATION

Fully automatic magazine handling and loading arrangements. Electrically driven twin launcher. Targets are designated to the system in three coordinates by radar. The system automatically tracks the target and points the launcher. When the target comes within range the missile is fired and intercepts the target using beam-riding guidance techniques. Typical radars are the RN Type 965 (**1560.253**) for primary long-range surveillance, Type 277 for height finding and the Type 901 which is the Seaslug tracking and illuminating radar. HE warhead with DA and proximity fuses. Four wrap round boosters.

DEVELOPMENT:

Development started in the early nineteen fifties. Prototype trials carried out in HMS *Girdleness* during late fifties. First fitted in County Class Destroyers in 1961.

STATUS.

Mark 1 system fitted in HM Ships *Hampshire, Devonshire, Kent* and *London*. Mark 2 system fitted in HM Ships *Glamorgan, Fife, Norfolk* and *Antrim*.

SEAWOLF SURFACE-TO-AIR MISSILE

DESCRIPTION:

Seawolf is the missile used in the Royal Navy's short-range self-defence missile system, GWS25. The system is designed to provide rapid reaction defence against both aircraft and anti-ship missiles. It is capable of installation in new and existing small escort vessels down to about 2,000 tons, full load, as well as in larger vessels. Lightweight derivatives of the GWS25 system, and known as Seawolf/Omega and Seawolf/Delta, have been studied for fitting in much smaller vessels of corvette size or possibly as little as 300 tons. Seawolf/Omega is a visually directed variant and Seawolf/Delta is a lightweight darkfire version.

The Seawolf missile employs line-of-sight guidance with radar differential tracking or television, both with radio command. Speed and manoeuvrability characteristics are suitable for the engagement of small Mach 2 missile and aircraft targets under severe weather conditions and sea states.

The complete GWS25 system comprises the following units:

—Air and low-air surveillance radars, Types 967 and 968
—Radar trackers, Type 910, and TV trackers
—Command transmitter
—Launcher and firing system
—Missile and handling frame
—Data handling
—Guidance Shaping Unit
—Operations Consoles
—Magazines

The Type 910 tracking radar is produced by Marconi and is described more fully in Section Three of this book (Entry No **1562.253**). The TV system is produced by Marconi-Elliott. The Type 967 and Type 968 surveillance radars provide both high and low cover, and also are produced by Marconi (Entry No **1561.253**). They are of modern design and incorporate features for air target detection up to high elevation angles as well as high performance against low-level and surface targets. Comprehensive precautions against sea and land clutter, as well as natural and man-made interference are incorporated.

The line-of-sight to a target is established by either the tracking radar or the TV system. Error signals proportional to Seawolf missile deviations from this datum are derived from the differential tracking radar or the TV system, and these signals are processed by a guidance shaping unit. Coded correction signals for missile guidance are produced and transmitted by microwave command link to bring the missile to the required flight path. In the GWS25 system the data processing required to interpret the tracking data and calculate the correction demand signals is based on the use of a Ferranti FM1600B computer (**1433.063**), which has been adopted as a standard.

A new multiple launcher developed by Vickers bears the designation Mark 25 Mod 0 and consists of six rectangular launch-tubes disposed in two banks of three, one on each side of an az/el mounting. Reloading is manual, presumably to avoid the complexity and particularly weight of an automatic system which might undesirably limit the number of ships which can carry the full Seawolf system. The launcher is separate from the tracking radar. High slewing rate and pointing accuracy are important features of the Seawolf launching which equipped for fully automatic firing sequence, with command override.

The Seawolf missile is about two metres in length and has four fixed wings (which may fold) and four moving tail fins. A solid booster motor is stated to give minimal launch drop and speed is quoted as being in excess of Mach 2. Successful techniques employed in Rapier (**2424.131**) have been incorporated, and no on-board test or repair facilities for missiles are called for. The HE warhead is provided with both proximity and contact fusing.

Operational Function:

Seawolf is being developed in such a way as to make it easy to fit the system into new and existing escort vessels. It is understood that it is planned to equip many Royal Navy ships with Seawolf in the mid-1970s.

For the successful interception of an incoming anti-ship missile great accuracy and an extremely short reaction time are required of the system. To achieve this it is being arranged that, once a target has been identified as hostile, all subsequent phases of the launch and guidance operation will be carried out automatically and without further manual control.

Other relevant features include the ability to fire salvoes, immediate readiness capability maintained over long periods, and extremely fast data handling facilities in all parts of the system.

Automatic radar and guidance is the normal operating mode, with TV tracking by an aimer for low angle of sight and surface target engagement.

Development and Manufacture:

In June 1967, the British Aircraft Corporation's Guided Weapons Division received a contract to develop the PX430 missile – which was subsequently given the name Seawolf. Development of the complete electronics system has been entrusted to the Marconi Company, whose responsibilities therefore include surveillance radars, target tracking radar, television, data handling equipment – a major part of which has been subcontracted to Ferranti – display equipment and guidance communications equipment. Marconi Radar Systems are also responsible for coordination of the complete shipborne system; and their Control Engineering department has the contract for the remote power control system.

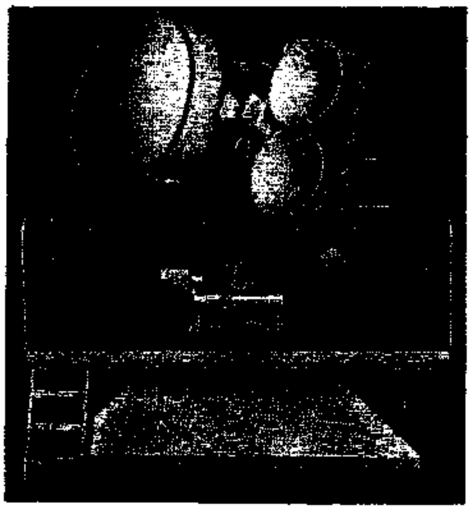
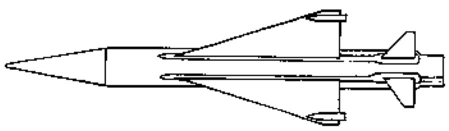
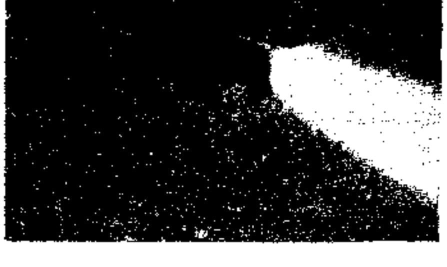
Model of Seawolf launcher



Model of Seawolf radar tracker and command guidance complex. Tracking data from this equipment could also be used for gun fire control purposes, or for other missiles



Seawolf (Provisional)



Seawolf in flight

STATUS:
Development of Seawolf is currently at an advanced stage and several test firings have been carried out. First ships to be fitted are currently planned to be the later Type 21 and the Type 22 frigates.
The development programme has recently been the subject of public criticisms, however, because cost and time estimates have been exceeded. It has indeed been suggested that the programme may be cancelled, but this is an unofficial view: the official reply to criticisms has been that having regard to the new ground being broken in the development, the cost-time overruns are not surprising.

SLAM CLOSE RANGE WEAPON SYSTEM

DESCRIPTION:
The initials SLAM stand for Submarine (or Surface) Launched Air Missile system. This system has been developed by Vickers to meet the need of submarines and light surface craft for an effective short range defence against other surface craft and helicopters.
For target engagement the system uses the Blowpipe (**2409.131**) missile for which a special multiple launcher is provided. This carries six missiles clustered around a central electronics enclosure which contains part of the missile control equipment, television camera and gyro sub-system for launcher stabilisation.
Control room equipment consists of an operator's display console, electronics cubicle which houses the power supplies and launcher control electronics, and a control unit for the CCTV system. An additional feature is a trainer/simulator which can be plugged into the display console to give the operator at sea training against simulated targets. Built-in test facilities are provided to enable routine servicing and rapid system checks to be carried out without the need for specialist personnel.

OPERATION:
In the submarine application one operator is required. Target acquisition is by means of the attack periscope, the launcher being automatically aligned with the target in azimuth when the launcher mast is raised. The operator then seeks the target's elevation and tracks it on his TV screen, controlling the launcher system by means of a thumb button controller which enables him to maintain the target in the screen centre. He then selects and fires the missile. When the missile is fired, the thumb button controller is disconnected from the launcher control circuits. The missile is automatically gathered on the line of sight and appears on the TV screen, at which point the operator controls its flight with the same thumb button controller. The launcher is able to continue tracking the target by means of a rate memory circuit which is built into the launcher control loop.
Missile range is at least 3,000 metres and may be greater against slow moving or stationary targets because less energy is required for manoeuvring. The warhead weighs 2.2 kg and is detonated by impact or proximity fuses.

DEVELOPMENT:
The system has been developed by Vickers initially to be suitable for use on the Oberon-class submarines but can be adapted for use in other types of submarine. SLAM can be fitted in new construction submarines or retrospectively.
Studies have been completed for fitting a surface version of SLAM to patrol boats, hovercraft and other coastal craft.

STATUS:
Sea trials on HM Submarine *Aeneas* were successfully concluded in November 1972 and established the accuracy and effectiveness of the system.

NAVAL BLOWPIPE MISSILE SYSTEM
DESCRIPTION:

Four different container fits for ship-board application of the successful Short Brothers & Harland Blowpipe anti-aircraft missile (**2409.131**) were announced at the Royal Navy Equipment Exhibition at Greenwich in September 1973. Originally developed as a man-portable defence system for the use of infantry against air and ground targets, subsequently adopted for the SLAM submarine defence system (**2446.231**) described above, the Blowpipe missile system has been developed by Shorts into a range of systems specifically for ship installation. Low weight and minimal launching effect permit its use on virtually any class of surface craft. The four versions range in both size and sophistication, but all are designed as compact container fits for direct deck mounting. The systems are:

(1) Manually Operated Twin-Launcher:

The simplest of the Blowpipe container fits, this system is independent of all ship's power supplies and is suitable for installation on the smallest vessels. It includes a manually-aimed twin-launcher and a 10-missile ready-use locker, all mounted on a rigid platform 1.68 × 2.87 m.

(2) Pedestal Director Sight System:

This system is based on the 10-missile Blowpipe launcher, controlled by a Seacat Pedestal Director Sight, and it incorporates an equipment compartment below the sight platform. It can be integrated with a variety of fire-control systems. The complete system is mounted on a 1.83 × 3.66 rigid platform. Space is available to mount a 10-missile stowage locker behind the equipment compartment.

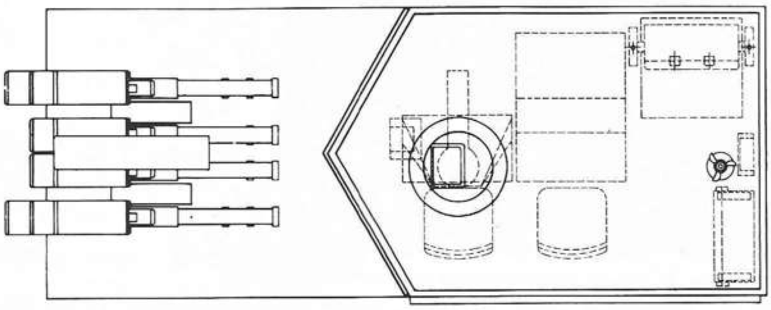
(3) Stabilised Periscope Director System:

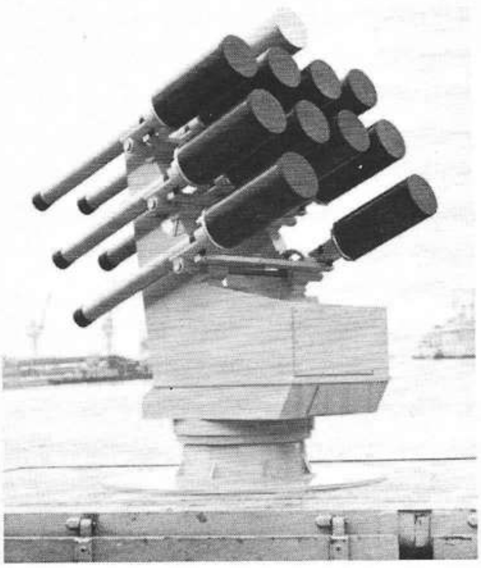
This Blowpipe container fit is based on the integration of the Kollmorgen Mark 35 gun director (**1666.261**) with the 10-missile Blowpipe launcher and CCTV aiming system. The complete container fit is mounted on a 1.83 × 4.5 m rigid platform. It is linked with ship's power supplies, communications and radar target information, and is operated by a crew of two.

(4) Automatic Target Tracking CCTV System:

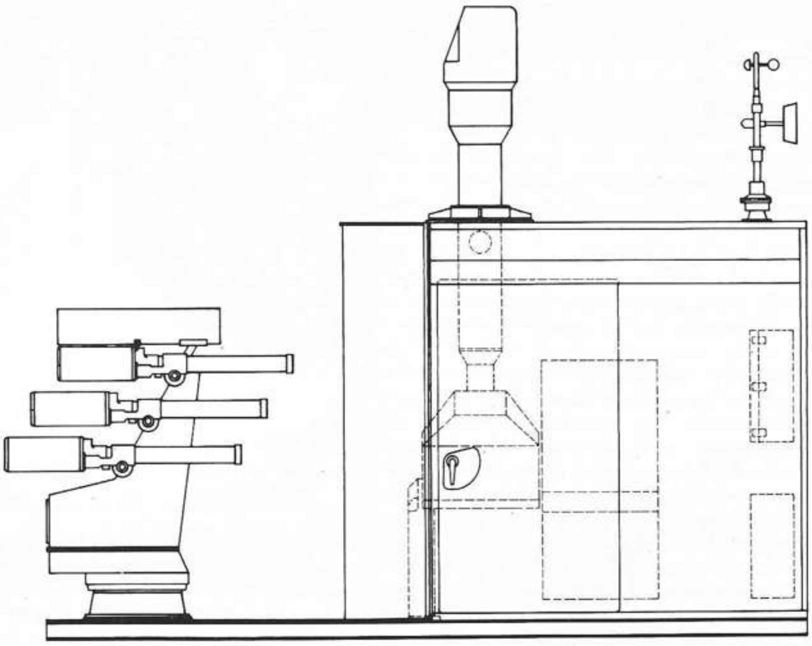
This TV auto-tracking system is the largest and most sophisticated of the Blowpipe container fits. It incorporates a modification of the Saab-Scania Aiming System, Type TVT 300/1 (Entry No **1231.383**) which has the ability to automatically track both surface and aircraft targets. It is a three-man operated system, the third man acts as

Smallest of the Blowpipe container fits, this twin-launcher/aimer installation can be bolted directly to the deck of any vessel





The 10-missile Blowpipe launcher used in the three larger container-fits



Layout of the Stabilised Periscope Director Blowpipe container-fit which uses the Kollmorgen Mk 35 director a look-out and can manually acquire the target in the TV sight. The sight can also automatically acquire the target from ship's radar target bearing indication. The complete system, with ten missile launcher, aiming system control console, launcher control unit and power supply unit, is mounted on a 2.44 × 5 m rigid platform.

STATUS:

No details of naval Blowpipe ship installation programmes had been notified at the time of closing for press.

2507.231
AEGIS SURFACE-TO-AIR WEAPON SYSTEM

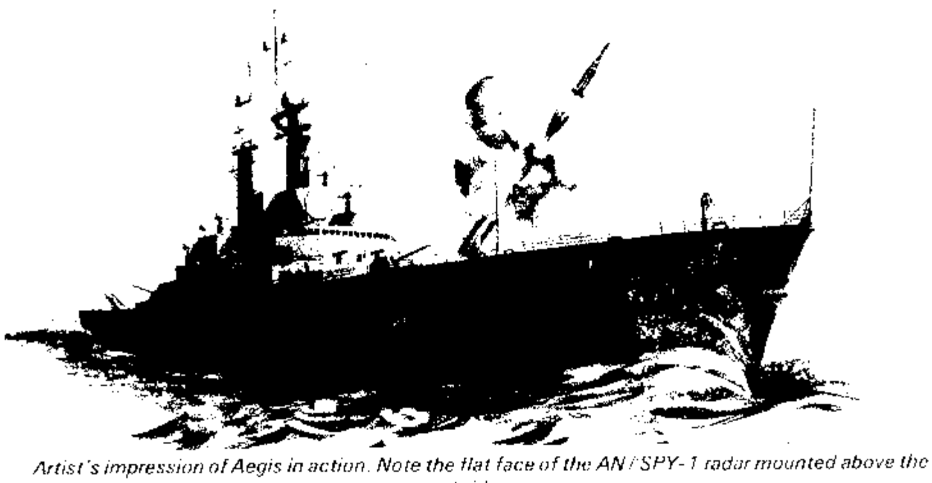
DESCRIPTION:

AEGIS, formerly designated the Advanced Surface Missile System (ASMS), is a surface-to-air weapons system primarily designed to defend against anti-ship cruise missiles. It is being developed as the US Navy's primary defensive missile system for the 1970s and 1980s. Present plans call for its installation aboard a new class of guided missile destroyers and frigates and possibly the "Nimitz"-class aircraft carriers, that will join the fleet beginning in Fiscal Year 1976. Aegis will be designed to destroy small, fast targets in hostile environments such as severe weather or countermeasure conditions. As an area defence system, Aegis will be capable of defending a task force which includes a carrier and several other types of ship. The system will complement and eventually replace the Tartar (**6006.231**) and Terrier (**6005.231**) missiles.

Major components of the Aegis system are the missile, its launching system, the fire control and weapon direction systems, the multi function array radar with its computer control, the system command and control and the operational readiness test system.

The missile to be used is the SM-2 modified Standard missile (**1122.231**). This is a semi-active radar homing weapon with provision for mid-course command guidance. It will be launched from the Mk 26 fully-automatic dual-purpose launcher which can also be used to launch Asroc (**6001.241**) anti-submarine missiles.

This launcher has a digital interface with the Mk 12 weapon direction system. One of the three computerised subsystems of Aegis, all of which use the AN/UYK-7 digital computer (**1467.063**), the Mk 12 system accepts weapon assignment commands and special threat criteria from the Mk 130 command and control system and tracking data from the multifunction radar. These inputs are processed to determine the possibility of



Artist's impression of Aegis in action. Note the flat face of the AN/SPY-1 radar mounted above the bridge engaging the target and then to generate commands for the Mk 26 launcher and pre-launch orders for the missile, commands for the Mk 99 fire control system for target illumination, commands to the multi-function radar, if mid-course guidance is required, and reports to the Mk 130 command and control system.

The function of the Mk 99 fire control system is to illuminate, and if necessary track, the target. To do this it uses either the Mk 90 (slaved) radar or the Mk 91 (tracking) radar. Inputs to the system come from the Mk 12 weapon direction system which, in the case of slaved radar operation is passing on data from the multifunction radar system.

The multifunction phased-array radar, the AN/SPY-1 (also known as the MFAR and described in entry **1570.253**) is a high-performance electronically-scanned equipment capable of surveillance and the simultaneous detection and tracking of multiple targets: it has been described as the heart of the Aegis system. Associated with it are four AN/UYK-7 computers and these equipments with ancillaries make up the Mk 110 radar control system. The primary function is, evidently, to search for and acquire targets and track them to whatever extent may be necessary. Beam scheduling for this and other tasks is organised by the computer. The system also handles the two-way link with the missile for mid-course guidance when requested by the Mk 12 weapon direction system. Certain special facilities can be provided such as a "burn-through" facility for use in ECM conditions or passive angle tracking. The system accepts general operational commands from the Mk 130 Aegis command and control system and mid-course guidance commands from the Mk 12 direction system; and its operational outputs are processed signals giving target detection data to the Mk 130 control system and target and missile track data to the Mk 12 director plus mid-course guidance commands to one or more missiles. Like all other operational subsystems in the Aegis system the radar control system is also connected to the Mk 545 operational readiness test system.

Together with the Mk 110 radar subsystem and the Mk 12 director, the Mk 130 command and control system make up the detection and decision loops of the Aegis system. The Mk 130 system is linked to the ship's command and control centre and targets enter the detection and decision loop from the AN/SPY-1 radar, from other ship's own sensors or from data supplied by other ships or aircraft. What happens next depends on which of the four Aegis operating modes has been selected. The modes are automatic special, automatic, semi-automatic and casualty; in the automatic special mode targets meeting certain predetermined threat criteria are automatically fired upon unless manual override is invoked; in all other modes positive human action to initiate firing is needed.

In these three modes the Mk 12 weapon direction system inserts targets into the engagement queue and schedules equipment for launching and terminal illumination. Trial intercepts are computed and a time to fire predicted. Resulting data are fed back to the Mk 130 command and control centre which is also receiving target detection data from the radar control system, operational readiness data from the Mk 545 operational readiness test system and electronic warfare and other data from the ship's command and control centre. Incorporated in the Mk 130 system is another AN/UYK-7 computer and a comprehensive display system; the AN/UYA-4. On the basis of all this data, threat evaluation and weapon assignment processes are carried out so that the engagement decision can be taken.

One of the eight AN/UYA-4 computer-controlled display consoles. This one provides missile fire control information to the Missile System Supervisor. The CRT shows a synthetic display with alpha-numeric labels and symbols. A smaller display above is used to present tabular information on a selective basis

Final major element of Aegis is the Mk 545 operational readiness test system (ORTS). This is linked to all the other major elements of the system and has the functions of continuously actively monitoring the state of readiness of each and of reporting the results of this process to the Mk 130 command and control centre.

Installation details so far available are meagre. There will probably be several kinds of Aegis installation, but it seems likely that the maximum installation – probably for the *Nimitz*-class aircraft carriers will have four AN/SPY-1 radar faces, about six tracking and illumination radars and two or three twin launchers.

DEVELOPMENT:

Initial planning for Aegis began in 1964, but further development was temporarily halted while a joint Army-Navy group was convened to study areas of possible commonality with the Army's SAM-D missile. Requests for Proposals were issued to defence contractors in June 1968, and the contract definition phase began on October 9 of the same year, when the Naval Ordnance Systems Command awarded contracts totalling \$18 million to the Boeing Company, General Dynamics Corporation, and Radio Corporation of America. RCA was awarded the engineering development contract for \$252,930,400 in December 1969.

STATUS:

At the end of April 1972 the US Navy and RCA jointly announced completion of the system design phase – including the critical design review and the initial testing of the AN/SPY-1 computer programs. Early in 1973, RCA announced satisfactory completion of the SPY-1 phased-array aerial tests, and prior to this successful tests of the SM-2 missile had been carried out including tests with mid-course guidance. In November 1973 the US Navy announced successful completion of land-based testing and the system was shipped and installed in USS *Norton Sound* for sea trials in mid-1974. On March 8, 1974, the AN/SPY-1 Phased Array Radar System simultaneously detected, automatically changed to tracking mode, and tracked more than 20 aircraft over the Pacific Ocean while operating in the US Navy test ship USS *Norton Sound*.

Installation is planned in a new DG-class ship of about 6,000 tons with a total ship cost of about \$125-million, and also in nuclear-powered DGN which has yet to be defined. Specific design and combat system integration efforts will be initiated in Fiscal Year 1975 to ensure a co-ordinated DG/DGN/Aegis development schedule. For these tasks the Fiscal Year 1975 Aegis funding allocation was \$67-million. In the same year \$32.2-million was allocated to the purchase of Standard SM-2 missiles for technical and operational evaluation.

MANUFACTURERS:

Prime Contractor: RCA Government and Commercial Systems, Moorestown, N.J. (Four major RCA divisions are engaged in the project.)

Parts of WDS Mk 12 and FCS Mk 99, Radar Type 90 and SPY-1 high-power transmitter: Raytheon Co.

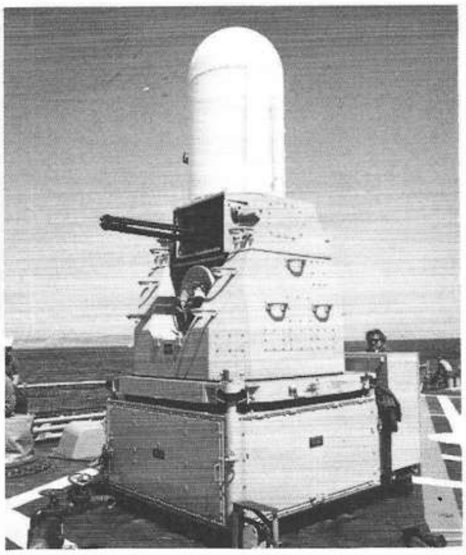
2543.231
CLOSE-IN WEAPON SYSTEM (VULCAN-PHALANX)

DESCRIPTION:

This system has been devised to provide a "last-ditch" defence against incoming missiles or high-speed low-level aircraft attacks. Based on the Vulcan (**2850.131**) low-level anti-aircraft system, the Close-in Weapon System (CIWS), or Vulcan/Phalanx as it is also known, depends for its chances of success on a fast automatic reaction to a threat and on the ability to put an intense barrage in the way of the incoming missile or aircraft.

An important feature of the CIWS is its fully automatic operation. The Vulcan gun will be associated with a search radar, a tracking radar and a fire-control computer (Phalanx), and the system will be so designed as to lock on an incoming target, evaluate the threat and, if the evaluation so



Close-up of Vulcan-Phalanx installation aboard USS King

indicates, *automatically* engage the target.

Characteristics of the Vulcan gun are described in entry number **2850.131** but it should be noted that the US Navy is proposing to use a new heavy bullet with great penetration capabilities.

Less well-defined is the possible associated missile element of the CIWS which is intended to complement the Vulcan gun in providing an inner zone defence against anti-ship missiles which have penetrated the longer-range defensive systems. In October 1973 it was announced that an improved version of the US Army's Chaparral air defence missile (**2542.131**) had been tested during the US Navy 'Hip Pocket-2' evaluation of ship defenses. The US Naval Weapons Centre system, called Chimp from Chaparral Improvement, uses the infra-red homing head of the AIM-9L Sidewinder on an existing standard Sidewinder. Another possibility is the so-called RAM, or 2.75-inch Dual-Mode Rolling Airframe Missile, a project which is linked with the US Army's Stinger development programme. The original infra-red seeker is retained but for the Navy project an RF head is added. This programme is being held at the advanced development stage until more practical information about the practical performance of missiles versus missiles has been obtained from operational tests which are planned for the coming year.

Trials installation of the Vulcan-Phalanx air defence weapon system on the helicopter deck of the USS King

In earlier Chaparral experiments the missile system was associated with a Ryan C-band coherent Doppler missile defence radar, capable of providing range bearing and velocity on target travelling at speeds between Mach 0.5 and Mach 2 with resolutions of 1 nm (1,850 m), 1 deg and 16 knots (30 km/h) respectively

A further development – and one which is common to the US Army Chaparral/Vulcan improvements – is the addition of a forward-looking infra-red (FLIR) system and a laser rangefinger to the weapon system to improve target acquisition in low-visibility or night conditions.

STATUS:

CIWS – being developed at high priority.

Sea Chaparral – experimental.

RAM – advanced development.

Fiscal Year 1975 funding for CIWS was $32.1-million, all for RDT&E.

MANUFACTURERS:

CIWS System contractor – General Dynamics/Pomona

—Vulcan Gun – General Electric

Sea Chaparral – Missile System – Philco-Ford/Aeronutronics

—C-band Radar – Ryan

—FLIR – Texas Instruments or Hughes Aircraft

RAM/Stinger – General Dynamics/Pomona

2770.231

POINT DEFENCE MISSILE SYSTEM (SEA SPARROW)

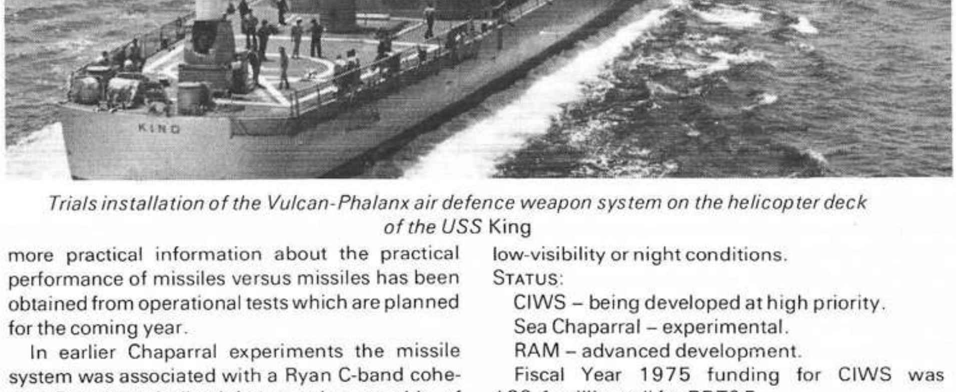
DESCRIPTION:

The Point Defence Missile System, also known as Sea Sparrow, is a close-in air defence system employing the AIM-7E Sparrow III missile (**1106.331**). The system, which is designed to counter the threat of enemy aircraft and anti-ship cruise missiles, consists of three parts; the Basic Point Defence Missile System, which became operational in 1969 and is now mounted on attack carriers, ocean escorts, an amphibious assault ship and the experimental ship USS Norton Sound; the Improved PDMS, currently in engineering development, and the Advanced PDMS, now in advanced development. The system is primarily designed for those ships which currently have no missile capability, including amphibious and auxiliary ships.

BASIC POINT DEFENCE MISSILE SYSTEM

The Basic Point Defence Missile System was assembled on an urgent basis from existing hardware. It features the Sparrow III missile launched from a modified eight-tube ASROC missile launcher. The launcher is housed on a modified 3-inch, 50 calibre automatic gun carriage. Total weight of the system is 17,690 kg.

A CW semi-active radar homing system is used. Target data from the Combat Information Centre are supplied to the manually-operated Mark 115 fire control system and the target is acquired and illuminated for homing guidance by a Mark 51 director/illuminator. This radar is trained and elevated manually by handlebar controls.



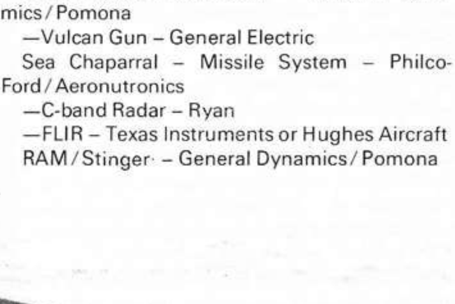
Basic Point Defence Missile System undergoing test on the USS Norton Sound

When target tracking begins, the launcher is fed train and elevation orders in synchronization with the director/illuminator. Pre-launch data and firing commands are relayed to the eight missiles housed in individual launcher cells. Weather doors open as each missile is launched and rear cell covers are either manually removed before launch or may be blown off by the rocket motor exhaust.

The missile is fired directly at the target but above the director-target line of sight. During flight the missile maintains a collision course with the target and at motor burnout is several hundred feet above the director-target line of sight and follows a downhill path against low-flying targets.

DEVELOPMENT:

BPDMS development began in 1964. In March 1972 an official US Navy statement revealed that



BPDMS missile (US NAVY PHOTOGRAPH)

80 BPDM System were "ready or in production" and that installation was scheduled for 30 ships in FY 1972. By May 1972 a total of 25 ships had been fitted and 16 of these installations had been made in FY 1972. Major contractors include Raytheon Corporation – Sparrow missile; General Electric – solid state power drive for fire control system, and Frequency Engineering Laboratories – fire control system.

IMPROVED POINT DEFENCE MISSILE SYSTEM

The Improved PDMS will incorporate a new lightweight eight-call launcher, a fire control system using digital computers, a Target Acquisition System (TAS) featuring a dual-mode sensor and a powered director/illuminator. The Sparrow missile family will still be used but in a modified form (RIM-7H). This version of the missile has folding fins which enable it to fit into a smaller launcher. The improved system will be produced as a co-operative effort by the US and five other NATO countries – Belgium, Denmark, Italy, Norway and the Netherlands. The participating countries will share development costs in relation to the number of subsystems each purchases. The US is expected to purchase approximately one-half of all systems produced.

The NATO Seasparrow programme, as the system is commonly called, was established by a Memorandum of Understanding in 1968 (the Netherlands joined the programme in May 1970). The contract definition phase began in 1968, and in September 1969 Raytheon Corporation was awarded a $23,109,600 engineering development contract calling for production of three engineering and development models. One system was to be tested by the US Navy, one sent to Norway for operational environment testing, and one to remain at Raytheon for systems evaluation.

The system is still in engineering development, but the US Navy requested $36 million to begin initial procurement in FY 1973. The first successful shipborne launch took place on March 31st 1972 when an IPDMS on the destroyer USS *Downes* acquired and tracked an incoming target and successfully fired its missile. Another prototype Sea Sparrow system was installed on board the Royal Norwegian Navy ship KNM *Bergen* in 1973. Pilot production of Sea Sparrow missiles for US and NATO was started by Raytheon in the latter half of 1973.

Sparrow missile launched from the development model hydrofoil Plainview *(AGEH-1). The launch was effected while the hydrofoil was foilborne*

Launch of Sparrow from the new type of launcher/canister which has been developed for this missile. The Sparrow is still resting on its foam launch pad, just before aerodynamic drag separates them. The launching cell from which the missile is fired is the same container as delivered to the ship, thus permitting a simplified and smaller construction than the conventional launcher cells seen on the left

ADVANCED POINT DEFENCE MISSILE SYSTEM

The third-generation Advanced PDMS will be developed by the US independently of the NATO effort on the Improved version. It will include a new missile of approximately the same dimensions as the Sparrow. This system is currently in the advanced development phase. Meanwhile Raytheon has completed the development of the AIM-7F Sparrow missile which has a longer-range radar seeker, a more powerful motor and more compact electronics.

DEVELOPMENT:

In November 1973 tests of a vertically launched version of Sparrow were carried out successfully at the US Naval Weapons Centre, China Lake, California. A modified AIM-7E2 missile, equipped with vanes of copper-impregnated tungsten which project into the rocket motor exhaust, was employed. The purpose of the vanes is to deflect the missile from its initial vertical path into a horizontal one directed towards the target. This pitch-over into the plane of the target is reported to occur within one second of motor ignition. The normal semi-active radar homing system is then responsible for guiding the missile to its target. For the China Lake tests the targets were Teledyne Ryan BQM-34A drones. This version of Sparrow is seen as a possible armament for large and small vessels for defence against anti-ship missiles.

VELARC

Experience gained with vertically-launched Sparrow experiments will be applied to another project known as Velarc (Vertical Ejection Launch Aero Reaction Control), which is a projected missile for use on hovercraft and hydrofoils at high speeds. The concept was initiated by Raytheon, and has subsequently gained USN support. The VELARC weapon will probably be of about half the volume of the AIM-7F air-to-air Sparrow III. In addition to its primary anti-ship missile intercept role, it will also have a surface-to-surface capability. A pre-charged pneumatic ejector is to be used to propel the missile from a below-deck launcher before the motor is ignited. Installations suitable for both large and small vessels are envisaged.

MANUFACTURERS:

Raytheon Company, Missile Systems Division, Bedford, Mass.

1122.231
STANDARD (RIM-66A & RIM-67A) SURFACE-TO-AIR MISSILE

DESCRIPTION:

The Standard ship-borne surface-to-air missile began life as a two-model range of anti-aircraft weapons, intended to gradually replace Terrier and Tartar with the US Fleet. The original two versions are the medium-range RIM-66A, and the extended-range RIM-67A. It was the first to be solid-state and is all electric with no pneumatic or hydraulically powered controls. Power for guidance and control is derived from a 'one-shot' battery which is activated just prior to missile launch. Use of a dry-storage battery is stated to ensure a reliable power supply even after the missile has been stored for long periods.

For both types, fully automatic magazine and loading facilities are provided for twin electrically driven launchers. The RIM-66A had a dual-thrust solid-propellant motor, and the RIM-67A used solid-propellant booster and sustainer rockets. Both versions are equipped with conventional high explosive warheads, with direct action or proximity fusing.

CHARACTERISTICS:

	(MR)	(ER)
Speed:	over Mach 2	over Mach 2.5
Ceiling:	over 20,000 m	over 20,000 m
Range:	greater than 18 km	greater than 55 km
Length:	4.57 metres	8.23 metres
Diameter:	30.5 cm	30.5 cm
Weight:	approx 590 kg	approx 1,060 kg

Subsequent developments have somewhat altered the original plan and versions of Standard have been or are in the process of development for surface-to-surface, air-to-surface and new surface-to-air applications. The following list is arranged in logical rather than chronological order.

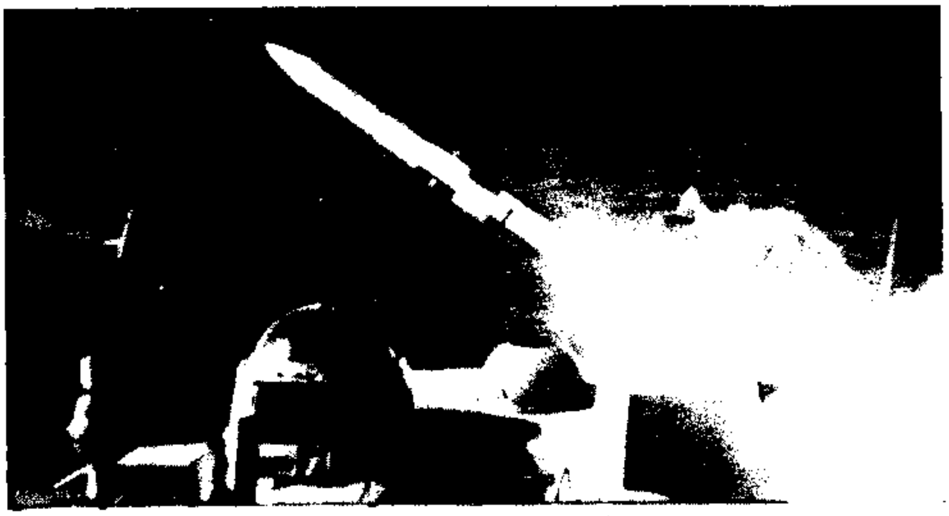
1. *Medium-Range and Extended Range*

All existing and most contemplated variants of the original missile can be made in either MR or ER versions. This possibility should therefore be borne in mind when examining the variants listed below.

2. *Standard 1 Missile (SM-1)*

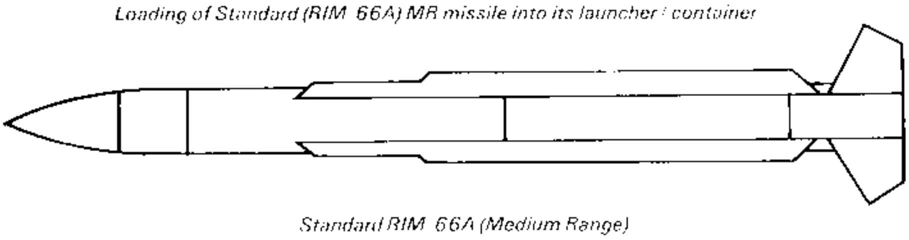
This is simply an improved version of the original missile and has superseded it. Its principal advantage over the earlier missile is that it has a (horizon-limited) surface-to-surface capability. It is expected to remain in production until 1975, is operational in over 70 missile ships and attack carriers and is one of the two missiles used in the Interim Surface-to-Surface Missile System (**2669.221**).

Procurement figures for the MR version in Fiscal Years 1973/4/5 are 340, 444, and 200, respectively at a total cost of $110.2 million. The comparable figures for the ER version are 100, 68 and nil, at a cost of $25.4 million.



Standard (RIM-66A) MR preparatory to loading

Loading of Standard (RIM 66A) MR missile into its launcher/container



Standard RIM 66A (Medium Range)

RIM-67A launch

3. *Standard 2 Missile (SM-2)*

At present this missile is still in development and is to be the missile used with the Aegis system (**2507.231**), at least when it is first deployed. In the MR version the SM-2 will have a range of over 48 km, while in ER form this will be doubled. Lengths of the two versions are 4.57 and 8.23 metres. An improved inertial reference will be provided, and to satisfy the requirements of the Aegis system the missile-born equipment has to be augmented by a two-way link for the mid-course command guidance. Fiscal Year 1975 funding for RDT&E amounted to $32.2 million.

4. *Standard ARM*

Essentially an airborne version (see entry number **1123.311**) this has also been adapted for use in a surface-to-surface role as part of the Interim Surface-to-Surface Missile System (**2669.221** and **2808.221**).

5. *Standard Active*

This is another development project which is aimed at producing operational missiles by 1975. The original intention was for this missile to serve as an interim anti-ship weapon until completion of Harpoon development, but delays with Active Standard have now made both missiles more or less contempories. The position at mid-1974 was that Active Standard would be maintained in development only until it was confirmed that it would no longer be required as a back-up to Harpoon. The missile will have an active homing head (radar seeker) and will be used as a surface-to-surface (presumably beyond-the-horizon) weapon.

OPERATION:

Details of the complex operational procedures of the Aegis system can be found under that system heading. The following description is appropriate to the use of the Standard missile as an anti-aircraft weapon with its own fire control system.

Targets are designated to the fire control system in three co-ordinates by surveillance radar. The tracker/illuminator radars, one per target and two per ship installation, automatically follow the targets and a digital computer provides data for the missile launcher pointing systems. Two missiles can be launched against separate targets within a period of a few seconds. The RIM-66A and the RIM-67A both use a semi-active radar homing guidance system.

DEVELOPMENT:

Development of the Standard missiles was started in December 1964 under a $13-million contract placed with General Dynamics. A further contract worth $23.8-million was awarded in July 1965 which covered continuted development work and production of an initial batch of 100 missiles. A full production contract, valued at over $120-million was placed in March 1967. Propulsion and warhead are the responsibility of the US Navy Ordnance System Command, and General Dynamics is providing guidance, control and fusing systems.

STATUS:

First ship fittings of the original missile types were made in 1968 and operational status was attained in 1969.

Progressive fleet fitting began in mid-1969 and by mid-1971 approximately 70 ships had been fitted, the installations being evenly divided between the MR and ER versions.

As noted above, the more recent Standard 1 version has now been extensively fitted and Standard 2 is in development. Several firing trials of the latter have now been carried out – including a mid-course guidance trial and a drone interception – all of which have been successful.

Standard 2 is expected to be in production in 1975 and to continue until 1977.

MANUFACTURERS:

General Dynamics Corporation, Pomona Division, 1675 West 5th Street, Pomona, California, USA.

1030.231
TALOS SURFACE-TO-AIR MISSILE

DESCRIPTION:

The Talos series of shipborne missiles is one of the most powerful in the US Navy inventory. Its main function is in the anti-aircraft role for fleet defence, but later versions are also capable of surface-to-surface operation. US military designations run from RIM-8A to RIM-8H.

The basic Talos missile is a beam-rider with a semi-active homing terminal phase. Propulsion is by solid booster and a ramjet sustainer motor. The latter burns a mixture of kerosene and naphtha, and total thrust is quoted as 20,000 lbs (9,070 kg).

CHARACTERISTICS:

Range: over 120 km
Ceiling: over 26,500 m
Speed: Mach 2.5
Length with booster: 9.53 m
Length less booster: 6.4 m
Body Diameter: 0.76 m
Span: 2.9 m
Firing weight with booster: 3,175 kg
Booster: Solid fuel
Sustainer: Liquid fuel ramjet

OPERATION:

Of the more recent variants in operational use the RIM-8F for high-altitude interception at long range employs beam riding mid-course guidance, with semi-active CW interferometer terminal guidance. A continuous rod warhead is carried. The RIM-8G is similar to the RIM-8E but with an improved homing system. The RIM-8H is provided with an anti-radiation homing head. This is probably the version intended for surface-to-surface missions.

Both HE and nuclear warheads are available with Talos missiles and in some ship installations there is provision for the remote selection of either type from the magazine for automatic loading onto the launcher.

STATUS:

The first US Navy vessel to be fitted with Talos was the guided missile light cruiser USS *Galveston*, from which the first firing at sea was made in February, 1959. At least six other USN cruisers have since been fitted.

Talos will probably eventually be replaced by the Aegis missile system (**2507.231**), but initially it will be the Tartar and Terrier missiles which will be replaced and Talos replacements will not start until Aegis has a longer-range missile than the SM-2: current plans call for Talos to remain operational until the early 1980s. The missile's standing in the US Navy was greatly enhanced when it was officially confirmed in the spring of 1970 that Talos missiles fired from the nuclear-powered cruiser USS *Long Beach* shot down two MiG jets over North Vietnam in May and September 1968. Both aircraft were flying at a distance in excess of 105 km from the cruiser when intercepted.

DEVELOPMENT:

Origins of Talos date back to the Bumble-bee programme of 1944, started by the Applied Physics Laboratory of Johns Hopkins University. Prime contractor for Talos is the Bendix Corporation's Missile Systems Division.

MANUFACTURERS:

Missile Systems Division, Bendix Corporation, Mishawaka, Indiana, USA.

APL, Johns Hopkins University – Weapons system integration.

Vitro Corporation – system co-ordination.

ASSOCIATED EQUIPMENT:

AN/SPG – 49 Target illuminating radar – Sperry

AN/SPG – 56 C-band tracking and guidance radar – Sperry

Talos (RIM-8)

6006.231
TARTAR SURFACE-TO-AIR MISSILE (RIM-24)

DESCRIPTION:

Tartar is a medium-range, supersonic surface-to-air shipboard guided missile system. It provides primary air defence for US Navy destroyers and destroyer escorts and secondary air defence for cruisers. The missile booster and sustainer rockets are combined in a single solid-propellant motor, thus facilitating installation on smaller ships.

OPERATION:

Tartar employs a fully automatic magazine handling and loading system. Targets are designated to the system in two or three co-ordinates by radar. The tracker/illuminator radars automatically follows the targets and a computer provides missile launcher pointing orders. Guidance is semi-active homing probably operating in X-band. The missile carries a high explosive warhead with DA and proximity fuses.

The rocket motor has two levels of thrust to achieve rapid acceleration. The guidance system computes a collision course, then steers to intercept by means of four hydraulically actuated tail fins.

CHARACTERISTICS:

Range: More than 16 km
Speed: Mach 2
Length: 4.6 m
Diameter: 30 cm
Weight: 680 kg
Motor: Dual-thrust solid-propellant
Guidance: Semi-active homing

DEVELOPMENT:

Developed shortly after Terrier system and first entered USN service in 1961.

STATUS:

Tartar is no longer in production but is still operational in a large number of US Navy ships and French, Italian, Japanese and West German navies. Replacement by the Standard missile (**1122.231**) has begun. An order for Tartar missiles, worth $31.3 million, was placed as recently as September 1973 by the Japanese Navy.

MANUFACTURERS:

General Dynamics, Pomona, for assembly and test. Vitro for systems co-ordination engineering. Target detection system Philco and Sperry Raytheon guidance.

ASSOCIATED EQUIPMENT:

AN/SPG-51 (**1247.253**) Guidance radar – Raytheon

Gun and Guided Missile Director Mk 73 (**2632.281**).

6005.231
TERRIER SURFACE-TO-AIR MISSILE (RIM-2)

DESCRIPTION:

Surface-to-air anti-aircraft missile for shipboard use. The Terrier series of missiles has been operational since 1956 and since then it has been the subject of continued development and improvement. The US military designation is RIM-2 and successive models have been denoted by letter suffixes running from RIM-2A to the latest version, the RIM-2F. The latter is also known as the Advanced Terrier.

CHARACTERISTICS:

Range: 35 km (est)
Ceiling: over 20,000 m
Speed: Mach 2.5
Overall Length: 8 m
Length without booster: 4.6 m
Body Diameter: 30 cm
Weight: 1,400 kg (app)

OPERATION:

Beam-rider guidance with semi-active homing is employed to direct the missile against a target designated by the ship's tactical data system. A twin launcher is supported by automatic magazine and loading arrangements. Terrier is launched by a solid fuel rocket booster and propelled by a solid fuel sustainer.

The normal warhead is of the HE type with direct action or proximity fuse, but one version of Terrier (RIM-2D) has been produced with a nuclear head.

DEVELOPMENT:

Development started about 1951, under the former military designation SAM-N-7, and Terrier was based upon the experimental LARK vehicle. First Terrier became operational in 1956.

Advanced Terrier (RIM-2F) became operational in 1963 and is carried by US Navy cruisers, frigates and attack carriers. It has also been purchased by the Italian and Dutch navies. The system will eventually be replaced by the Standard missile system (**1122.231**).

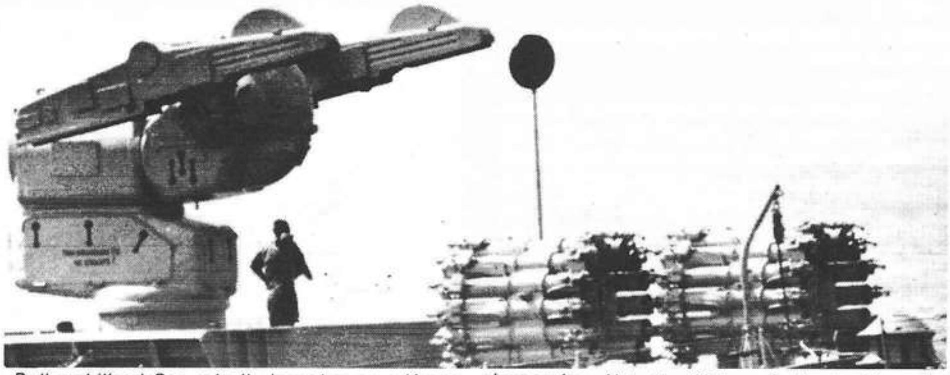
THE UNION OF SOVIET SOCIALIST REPUBLICS

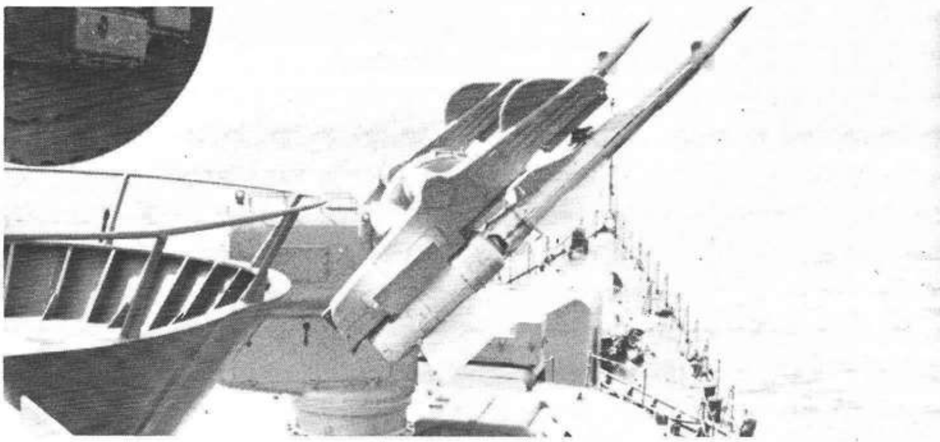
2939.231
GOA SHIPBORNE SURFACE-TO-AIR MISSILE (SAN-1)

DESCRIPTION:
Known also by the US alphanumeric code SAN-1 the missile whose NATO code-name is Goa is the principal surface-to-air missile of the Soviet Navy. It is fitted to the "Kanin", "Kashin", "Kotlin", "Kresta" and "Kynda" classes on scales ranging from one to four twin launchers.



Roll-stabilised Goa missile launcher on a Kresta *class cruiser. Note the 12-barrelled trainable anti-submarine rocket launchers*

The shipborne Goa missile is assumed to be identical with the ground-to-air missile (**2938.131**) but the equipment associated with it is very different. The standard launcher is clearly roll-stabilised as can be seen from the accompanying illustration. Rather different, and not obviously stabilised, launchers have also been observed, but these are most probably not for Goa. The launcher is mounted on top of the missile magazine and is reloaded vertically through small hatches.

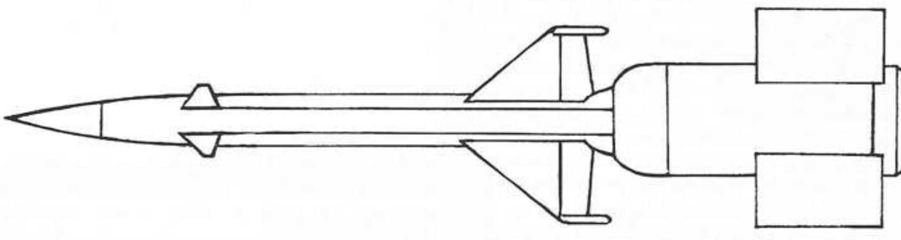


Goa shipborne anti-aircraft missiles on Kashin *class destroyer. Radar in the left foreground is probably a Tellerform-2 director for the guns forward of the missiles' launcher* (NOVOSTI)

Associated with the missile in all installations is a compound radar systm known by the NATO code-name Peel Group (**1323.253**) and described in the Naval Radar section.

There is, of course, no definite information on Goa's performance but it is generally taken to have maximum slant range of about 15 km and a ceiling of some 12,000 metres. Length is estimated at about 5.9 m and the maximum span at 1.2 m.

STATUS:
Entry into service with the Soviet Fleet was in 1961-62. According to the latest available figures, Soviet vessels are equipped with a total of 128 launchers. There are two on each of 8 SAM "Kotlin" class, 6 "Kanin" class, and 4 "Kynda" class ships; while 19 "Kashin" class, and 4 "Kresta I" class vessels each have four SAN-1 launchers.

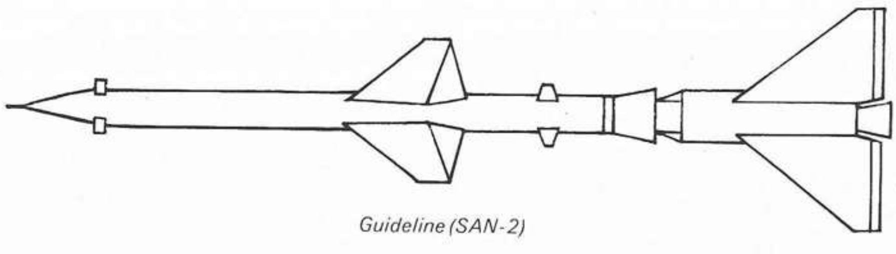


Goa (SAN-1)

2943.231
GUIDELINE SHIPBORNE SURFACE-TO-AIR MISSILE (SAN-2)

DESCRIPTION:
Guideline, also known, in its shipborne application, by the US alphanumeric code SAN-2, has been installed in only one Russian ship, so far as is known at present – the cruiser *Dzerjinski*.

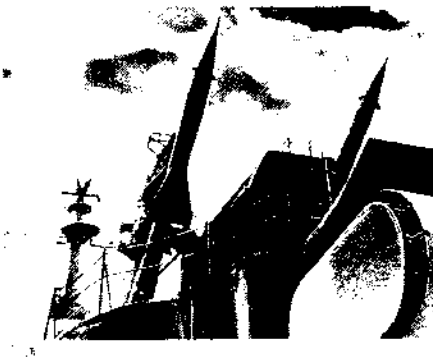
It has been suggested that one reason for this is



Guideline (SAN-2)

the difficulty of providing suitable stable platforms on smaller vessels for the flapping Fan Song (**2866.153**) radars used to guide these missiles. It could also be that the relative difficulty that there appears to be in gathering these missiles to the required flight path presents even more of a problem in shipborne installations than it does on the ground.

So far as is known the general performance of Guideline as a shipborne missile is substantially the same as that described in the entry for the ground-based version.



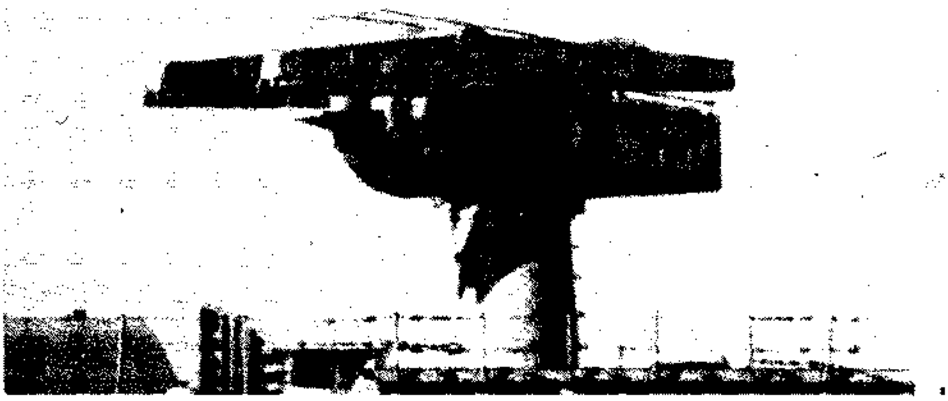
Guideline shipboard installation (NOVOSTI)

2947.231
GOBLET SHIPBORNE SURFACE-TO-AIR MISSILE (SAN-3)

DESCRIPTION:

The helicopter-carrier *Moskva* and the "Kresta-II" class cruisers are equipped with a surface-to-air missile that is similar in size to Goa (**2939.231**) but possibly larger and certainly launched from a different launcher and directed by a different radar complex.

Although there was confusion concerning this missile it now seems to be agreed that it is that classified in the American code as SAN-3: it is also widely believed – without, of course, any official confirmation – that its NATO code-name is Goblet.



SAN-3 missile launcher on Kresta II *class cruiser*

The launcher, illustrated here, does not appear to be roll-stabilised – suggesting that the missile gathering is efficient. The nature of the missile itself is unknown although various suggestions have been made. One suggestion, that appears to be consistent with the general Russian practice of making maximum use of any successful development, is that the missile is that known as Gainful (SA-6) (**2930.131**) and is a surface-to-air weapon of more modern design than Goa. Fire control radar has the NATO code "Head Lights" (**1328.253**). While the identification of Gainful with Goblet cannot be asserted, the suggestion has authoritative support.

STATUS:

Goblet-type launchers have been sighted on the two "Moskva" helicopter carriers, 6 "Kresta II" cruisers and on a "Kara" class ship. In all cases, each ship had four launchers, to make a total of 36.

2954.231
SAN-4 SHIPBORNE SURFACE-TO-AIR MISSILE

DESCRIPTION:

This designation (SAN-4) has been allocated to whatever missile system is concealed within the 'bin-type' launcher assemblies which first appeared on the Nanuckha missile boats and "Krivak" destroyers and spread fairly rapidly to a number of other classes of Soviet Navy ship. A form of retracting mechanism is involved so that a kind of 'pop-up' missile launching mode is possible, and a twin launcher is employed. Most reports assign a close-in air defence role to the SAN-4, with some observers stressing the anti-helicopter aspect. Each SAN-4 'bin' is associated with a fire control radar group of a new type (reportedly code-named "Pop Group"), and which the Soviet Navy has been to some pains to shield from Western eyes to date. As for the missile itself and its possible configuration and mode of guidance, the lid of its shipborne silo is totally inadequate evidence upon which to embark on any worthwhile conjecture.

STATUS:

According to the latest figures available, the Soviet Fleet has at least 31 SAN-4 launcher installations on five classes of vessel. Two converted Sverdlov cruisers have one each; the new "Kara" class of cruisers have two amidships; five "Krivak" class ships each have two; six Nanuchka missile boats have one each; and eleven "Grisha" class corvettes have a similar foredeck installation to the Nanuchkas.

A rare picture of the SAN-4 missile launcher outside its 'silo'. The associated Pop Group radar can be seen on the raised platform to the left; Drum Tilt radars are for gun fire control

SURFACE TO SUB-SURFACE WEAPON SYSTEMS

INTRODUCTION – ANTI-SUBMARINE WARFARE

Classification of anti-submarine warfare systems and equipment in a manner compatible with the general arrangement of this book presents several difficulties – which, in general, have to be resolved in an arbitrary way. Torpedoes, for example, can be launched from tethered mines, submarines, surface ships, drones, helicopters and fixed-wing aircraft and can be aimed at either submarines or surface craft; and torpedoes of many types can be used in more than one of these roles. Because of this general and individual versatility we have grouped all kinds of torpedo together in the general area of sub-surface weapons.

Because of the complexities of the subject the reader may find it necessary to consult one or more of the following sections of the book in order to find the information he requires.

Section One
(a) This subsection – dealing with shipborne anti-submarine weapon systems
(b) Torpedoes
(c) Underwater Weapons (Subroc)
(d) Naval Fire Control and Action Data Automation Systems – for weapon control systems

Section Two
(a) Fighting Ships – for ASW vessels &c.
(b) Submarines – for hunter-killer submarines &c.
(c) Military Aircraft – for ASW aircraft

Section Three
(a) Shipborne Anti-Submarine Weapons – as distinct from systems (often an arbitrary decision)
(b) Sonar and Underwater Detection Equipment
(c) Data Processing Equipment
(d) Ancillary Equipment – Guns and Missiles
(e) Simulators and Trainers

AUSTRALIA

ANTI-SUBMARINE MORTAR SYSTEM

DESCRIPTION:

An improved version of the AS Mk 10 (Limbo) anti-submarine mortar system (**6008.241**) has been developed in Australia. The design of the Limbo system dates from about 1955 and technological advances since then made it possible to overcome certain disadvantages of the system. In particular, the new development eliminates the use of rotating electric machinery in the pitch and roll servo loops – with consequent saving in power, deck-level weight and noise – to reduce the weight and noise level of the loading mechanisms (pneumatic for Limbo) and to eliminate the mechanical problems that can arise from the use of uniselectors in the fuse-setting system.

In the new design the metadyne servo control system for pitch and roll has been replaced by an electric system using silicon-controlled rectifiers to control the launcher drive motors; the pneumatic rammer has been replaced by a smaller and lighter electrical device; and the fuse setting system has been redesigned to use solid-state logic circuits with which have been incorporated additional supervisory circuits that permit checking of the setting before launch.

One effect of all these changes – apart from reduction in cost, weight and noise – is a manning reduction from seven to three.

STATUS:

Production equipments are being delivered to the Royal Australian Navy.

MANUFACTURERS:

Sponsoring Organisation: Department of Supply – Weapons Research Establishment, Salisbury, S.A., Australia.

Contractor: Hawker Siddeley Electronics Ltd., Brookvale, NSW.

6002.241
IKARA ANTI-SUBMARINE WEAPON SYSTEM

DESCRIPTION:

The concept of Ikara is the employment of a guided missile to deliver a homing torpedo to the target submarine. The missile is launched from a surface ship which uses a computer to calculate the torpedo dropping position, from information fed into the computer from the ship's sonar and other sources of information on the submarine's position.

The guidance system ensures that the missile flies to the continuously up-dated optimum dropping position, derived from target information fed into the computer during flight.

After release from the Ikara vehicle, the lightweight torpedo (such as the Mk 44) descends by parachute to the sea, where it searches for the target submarine and carries out a homing attack

The missile is about 310 cm long with a wing span of approximately 150 cm; propelled by a dual thrust solid fuel rocket motor, and carries a control system and autopilot to enable the vehicle to be steered in flight.

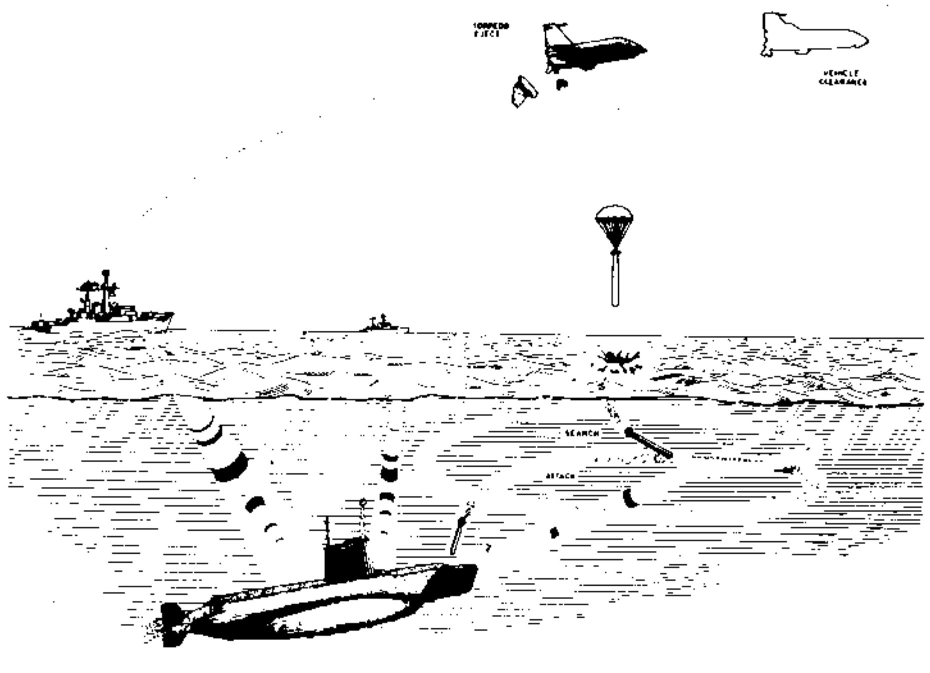
OPERATION:

Ikara is capable of attacking enemy submarines out to the maximum range of the ship's sonar regardless of the weather conditions.

In addition, an Ikara attack can be carried out on information received from another ship, or a helicopter equipped with dunking sonar. In this case target information is passed to the firing ship's computer, and an attack is carried out in the normal manner, even though the firing ship itself is not in contact with the target.

This mode of operating has been successfully proved in trials and considerably enhances the potential of Ikara to provide long range ASW capability.

In the self-contained mode of operation a ship mounted radio/radar system enables the missile to be accurately tracked and guided to the drop zone, where command signals initiate the torpedo release function



Attack sequence of Ikara ASW weapon system

Target information from the ship's long range sonar is fed into a computer which calculates the dropping position, taking into account such factors as ship's own course and speed, the prevailing wind, and target movement during time of flight. The outputs from the computer are passed to the missile via the guidance system.

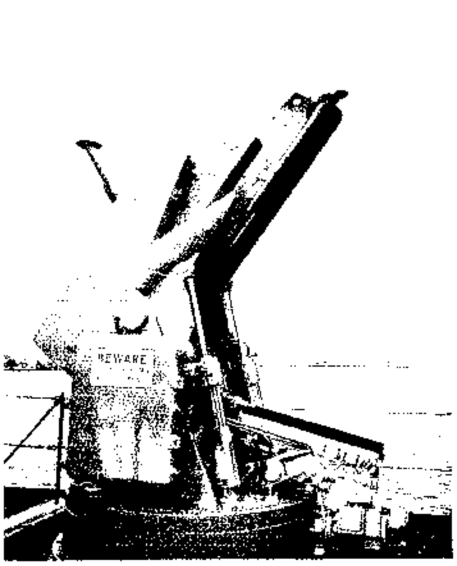
In the Australian version the computer is a digital system autonomous to the Ikara system. The Royal Navy version (specifically known as RN Ikara) takes computer service from the action data automation system (ADAS).

The Ikara launcher ensures that the missile takes up its correct flight path as quickly as possible, whilst the automatic handling system ensures rapid reloading from the magazine, where the missiles are stowed with their torpedoes attached.

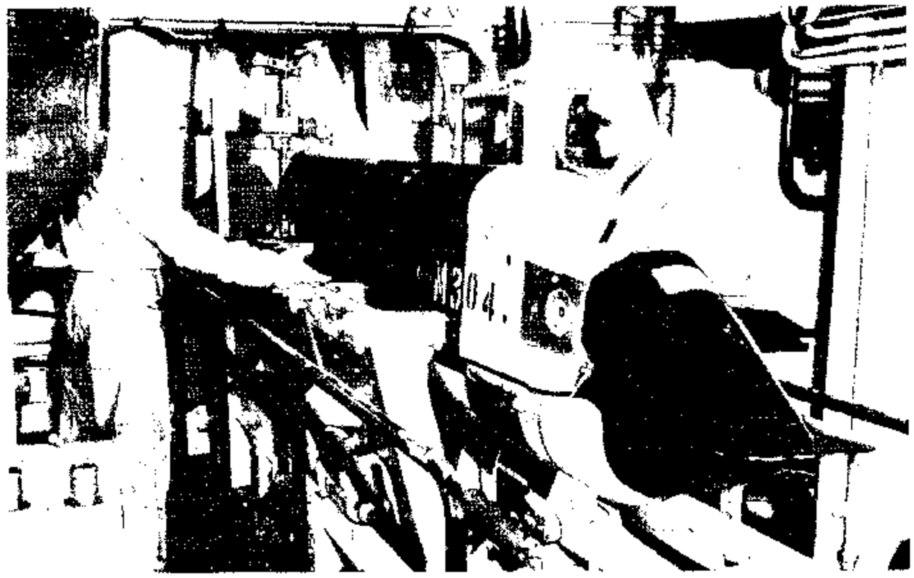
The layout of the magazine and handling area varies considerably between the classes of ships already fitted with Ikara, and designs are available to cater for the differing requirements of ships ranging from 1,500 tons upwards.

DEVELOPMENT:

Initial design was undertaken by the Australian Department of Supply and Department of the Navy. The modified version to meet Royal Navy requirements was subsequently embarked upon



Ikara missile on its launcher on board HMAS Perth



An Ikara anti submarine missile seen in the below-decks magazine and launch preparation area. An automatic handling and loading system ensures rapid reloading of the launcher

as a joint programme.

Branik

Even more recently, the requirement to fit Ikara to the Brazilian "Niteroi" class Mk 10 frigates has given rise to the development of a third version of the system. Known as "Branik", this version again differs from the Australian and RN versions in the way in which the launcher and missile obtain computer service. In the "Niteroi" weapon control system two fire-control computers (Ferranti FM 1600B **1433.063**) are used to control all the ship's weapons. The Branik system employs a special-purpose missile tracking and guidance system which is fully integrated with one of these computers. A lightweight semi-automated missile handling outfit is also incorporated in the new version.

Branik is the subject of a joint development programme by the Department of Supply, Vosper Thornycroft, Hawker Siddeley Dynamics and Ferranti.

STATUS

In service with the Royal Australian Navy and the Royal Navy. Ordered by the Brazilian Navy. Other orders pending.

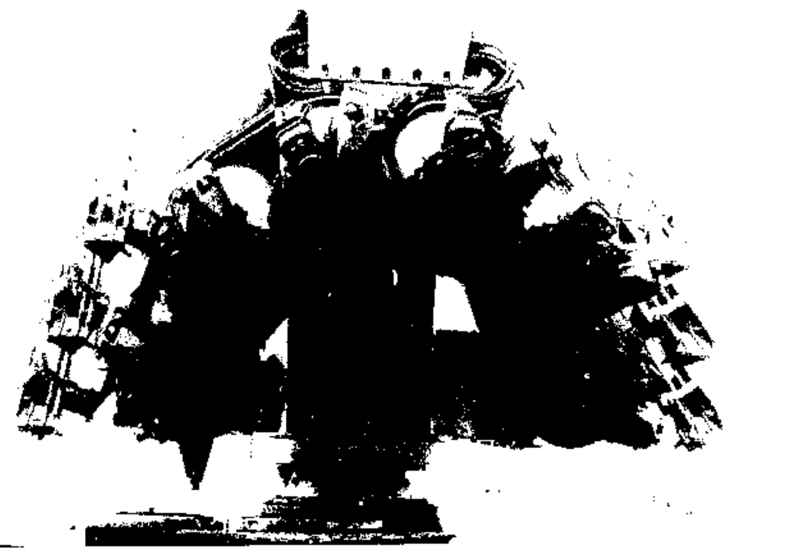
ANTI-SUBMARINE WEAPON SYSTEM

DESCRIPTION:

This system comprises an anti-submarine rocket launcher associated with a sonar and a computer. The rocket launcher is remotely controlled, aiming and rocket fusing being determined by the computer, which in turn receives input data from the sonar.

The launcher is made by Creusot-Loire under licence from Bofors and is a 6-tube device with automatic reloading from a magazine. It fires single rockets or salvoes as required, and will accept any of the range of Bofors 375 mm rockets, thereby giving a choice of ranges from about 260 metres to about 3,600 metres. Rate of fire can be up to one round per second.



Rear view of the CAFL built sextuple rocket launcher

The computer is by Thomson-CSF and is of the type used by the French Navy. It calculates ballistic data for initial velocities of 70, 90, 100 and 130 metres/sec for the different rockets that may be used with the systems.

Input data from the Alcatel sonar comprise the location and rate of change of position of the target.

STATUS:

Development started in 1954 and three types of system have been produced – the latest of which went into service with the French Navy in 1967.

MANUFACTURERS:

Launcher: Creusot-Loire, 12, rue de La Rochefoucauld, -75- Paris 9e.

Computer: Thomson-CSF

Sonar: Alcatel.

1179.241
MALAFON SURFACE TO SUB-SURFACE MISSILE

DESCRIPTION:

Naval weapon consisting of a radio command guided winged vehicle carrying a homing acoustic torpedo. Mainly intended for use from surface vessels against submarines, but may also be used to attack surface targets.

The Malafon missile has the appearance of a small conventional aircraft with short, unswept tapered wings, and a tailplane fitted with end-plate fins. Principal dimensions are: length 6.15 m, diameter 0.65 m, wing span 3.3 m, and the launch weight is 1,500 kg. Maximum range is about 13 km.

OPERATION:

The missile is ramp launched and propelled by two solid-fuel boosters for the first few seconds of flight. Subsequent flight is unpowered. A radio altimeter is fitted to the missile to maintain a flat trajectory at low-level. On reaching the target area, approximately 800 metres from the target's estimated position, a tail parachute is deployed to decelerate the missile. The homing torpedo is thus ejected from the remainder of the vehicle and enters the water to complete the terminal guidance phase of the attack by acoustic homing.

Target detection and designation in the case of submerged targets is by means of sonar and by radar in the case of surface targets. These sensors, as appropriate, are used during the flight of the missile to provide data on the target for the generation of command guidance signals which are sent via radio command link to guide the missile. Missile tracking is aided by flares attached to the wing tips.

DEVELOPMENT:

Development started in 1956 and by 1959 a total of 21 test launches had been made, 15 from the ground and six from an aircraft. The first sea launch and guidance test took place in 1962. Evaluation of the complete weapon system took place in 1964, during which time over 20 launches were made. Operational trials were carried out the following year.

STATUS:

It is understood that Malafon was deployed in an interim form on French Navy vessels, while full development trials were still in progress, these installations probably being up-dated as development continued. These fittings have been referred to as Malafon Mk 1 systems. Deployment of the latest versions includes installations in the guided weapons frigate *Suffren*, five modified T.47 class destroyers and five corvettes.

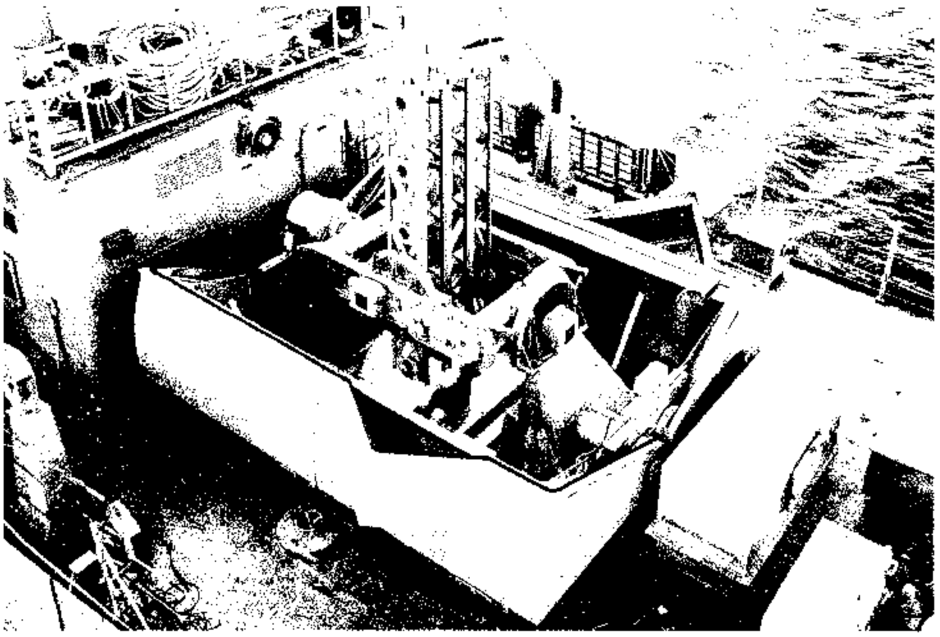
TERNE III SURFACE TO SUB-SURFACE MISSILE

DESCRIPTION:

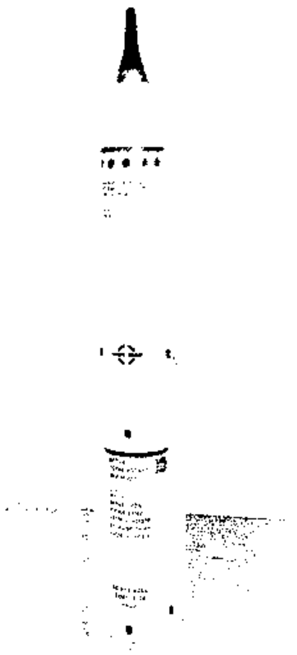
Shipborne medium/short range anti-submarine unguided multiple missile system.

OPERATION:

Ship's sonar provides submarine position for prediction of the Terne launcher elevation and bearing data. The six barrelled launcher can be used for firing single or multiple salvoes of solid fuelled rockets on an unguided trajectory. Hydrostatic fuses fire charges at predetermined depth. A six-missile salvo can be fired in 5 seconds. Reload time is 40 seconds, and is automatic.



Six-round launcher for Terne Mk 8



Terne MK 8 anti-submarine missile

CHARACTERISTICS:

Range: Probably about 3 km

Firing Sector: 360 degrees

Launcher: Sextuple remote-power-controlled. Automatic loading from manually loaded magazine hopper. Special launcher protection against ice and arctic conditions

Missiles: Length 2.0 metres. Diameter: 20 cm. Fusing: Hydrostatic and DA

DEVELOPMENT:

Development, by Kongsberg Vapenfabrik, started about 1960. The system is operational in ships of the Norwegian and US navies

STATUS:

Fitted in Royal Norwegian Navy and US Navy ships.

MANUFACTURERS:

Kongsberg Vapenfabrik, Postbox 25 N-3601, Kongsberg, Norway.

SWEDEN

6021.241

TYPE 375 SHIPBORNE ANTI-SUBMARINE MISSILE SYSTEM

DESCRIPTION:

Shipborne surface to sub-surface medium range anti-submarine unguided missile system.

OPERATION:

Ship's sonar provides submarine position for prediction of Bofors 375 launcher elevation and bearing data. The launcher has either two or four tubes and can fire single or multiple shot salvoes. A special design of missile nose ensures a predictable and accurate under-water trajectory. The launcher is reloaded by automatic means from the magazine which is disposed directly below the launcher. Bofors launchers are described in section 3GI (**2368.203** and **2369.203**).

Missiles have three types of rocket motor giving differing range brackets. The missile trajectory is flat thus giving a short time of flight to minimise target evasive action. Fuses are fitted with hydrostatic and DA devices. Rocket characteristics are:

M/50: weight 250 kg, range 300-830 m

Erika: weight 250 kg, range 600-1,600 m

Nell: weight 230 kg, range 1,520-3,600 m

DEVELOPMENT:

The initial version of the system, comprising the four tube launcher and the M/50 rocket, was developed in the early 1950s, and became operational about 1956. The two-tube launcher was developed in 1969-72 and the Nelli rocket in 1969-73. A version made in France by Creusot-Loire under licence from Bofors is described in **2057.241** above.

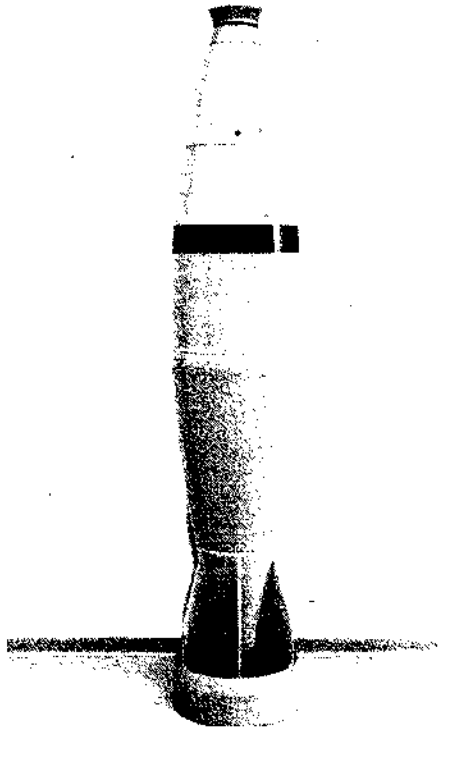
STATUS:

Fitted in Swedish Navy vessels and used by many other navies.

MANUFACTURERS.

Launcher and missile: Bofors AB, Bofors, Sweden.

Predictor system: Various – e.g. Philips Teleindustri, Sweden; Ferranti Ltd, England and N.V. Hollandse Signaalapparaten, Netherlands.



375 mm anti submarine rocket

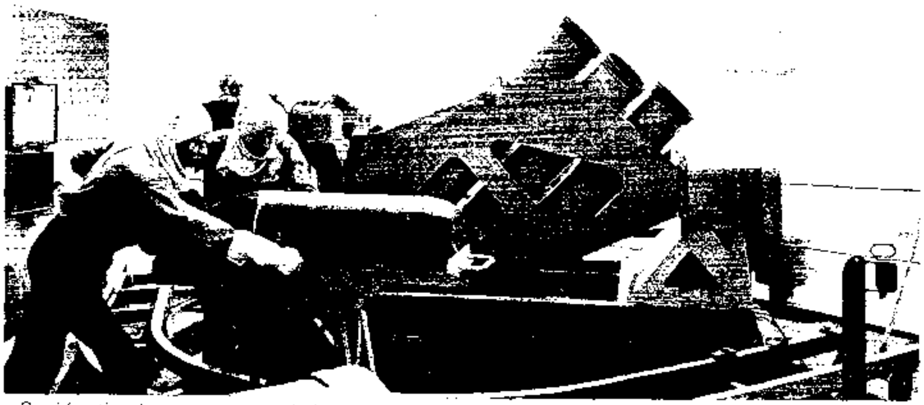
THE UNITED KINGDOM

6007.241
SQUID ANTI-SUBMARINE MORTAR SYSTEM

DESCRIPTION:
Shipborne surface-to-sub surface medium range anti-submarine mortar system.

OPERATION:
Ship's sonar provides submarine position data to a predictor which computes mortar aiming position. The triple-barrelled mortar fires a pattern of three mortar bombs which are programmed to give a three dimensional explosive pattern ahead of the target. The bombs can be set to explode at variable depths using hydrostatic fuses and are also fitted with DA fuses.
Weight of the projectile is about 200 kg and range is limited to about 400 metres.

DEVELOPMENT
Developed by the Admiralty Underwater Weapons Establishment in the nineteen-forties. Ship fitting started in about 1948



Squid anti-submarine mortars being loaded on board HMS Cambrian (Official MoD (Navy) photo)

STATUS
Operational in the Royal Navy and other Commonwealth navies. Must be considered as obsolescent

MANUFACTURERS:
Manufactured to MOD (Navy) designs by several contractors.

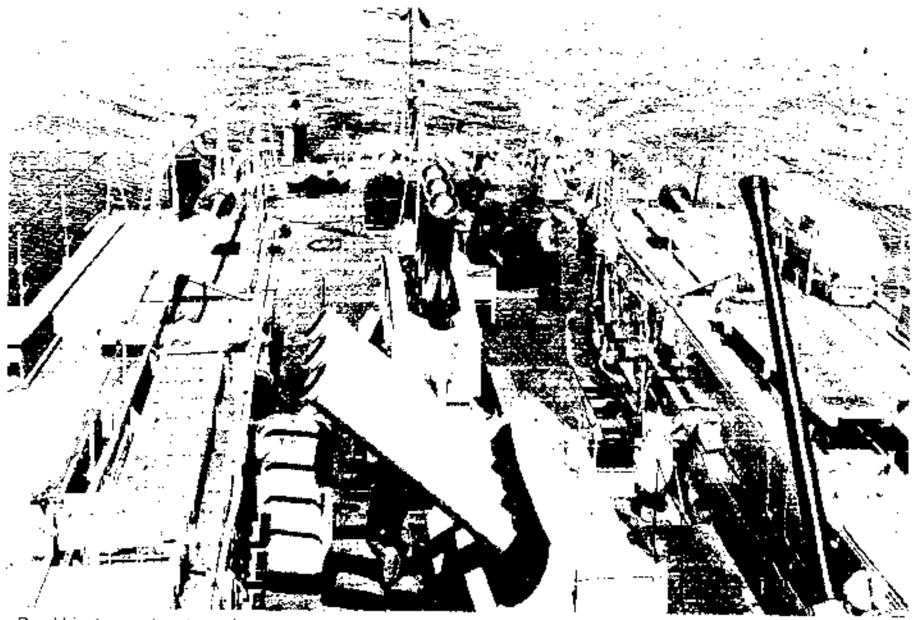
LIMBO ANTI-SUBMARINE MORTAR SYSTEM (AS Mk 10)

DESCRIPTION:
Shipborne surface-to-subsurface medium-range anti-submarine mortar system. Mortars are stabilised in pitch and roll by a metadyne system referenced to the ship's stable platform.

OPERATION:
Ship's sonar provides submarine position data to a predictor which computes mortar elevation and lateral tilt. The triple-barrelled mortar fires a pattern of three mortar bombs which are programmed to give a three dimensional explosive pattern ahead of the firing ship. The bombs can be set to explode at variable depths using hydrostatic fuses and are also fitted with DA fuses. The fuse setting is by remote control through relays and uniselectors. Loading is accomplished by pneumatic power horizontal ramming from a magazine which is located alongside the mortar.
Weight of the projectile is about 200 kg and range is somewhere between 1,000 and 2,000 metres – estimates vary.

DEVELOPMENT
Developed by Admiralty Underwater Weapons Establishment during the nineteen-fifties. Ship fitted in the early nineteen-sixties.

STATUS.
Operational in British and Commonwealth destroyers and frigates and in many other vessels. See also entry number **2018.241** for modified Australian version



Dual Limbo anti-submarine mortar installations (Official MoD (Navy) photograph)

MANUFACTURERS:
Manufactured to MOD (Navy) designs by several contractors.

THE UNITED STATES OF AMERICA

6001.241
ASROC ANTI-SUBMARINE SYSTEM

DESCRIPTION:
ASROC (RUR-5A) is an all-weather, day or night, ship-launched ballistic missile carried as the primary anti-submarine warfare weapon aboard US Navy destroyers as well as some cruisers and frigates. The weapon consists of a Honeywell Mark 46 acoustic homing torpedo or a nuclear depth charge attached to a solid propellant rocket motor. It can be fired from an eight cell launcher, the Mk 46 launching system, or from the Mk 10 Terrier missile launcher (ASROC / Terrier system).
Other major components include a fire control computer and an underwater sonar detector. Honeywell Inc. is the prime contractor.

OPERATION:
After launch the weapon follows a ballistic trajectory. The rocket motor is jettisoned at a predetermined point and the payload continues toward the target. If the payload is a torpedo, it is lowered to the water by a parachute, where its homing mechanism is activated upon submersion. Depth charge payloads sink to a predetermined depth before detonating.
Range of the weapon is classified but has been estimated at from 2-10 km. The missile is 4.6 metres long, has a diameter of 32.5 cm and a span

Underwater explosion resulting from an ASROC missile fired from the destroyer USS Agerholm. *ASROC launcher can be seen between the destroyer's smokestacks* (Official US Navy photograph)

Modified ASROC missile on the Terrier launcher of the USS Belknap

ASROC launch from the guided missile escort ship USS Brooke (Official US Navy photograph)

of 84.5 cm. Launch weight is about 435 kg.

DEVELOPMENT:

ASROC has been in development since 1955. The first development contact was awarded to Honeywell in June of the following year. After a successful two-month evaluation aboard the USS *Norfolk* in 1960, the weapon became operational on four destroyers in 1961. It is now operational on eight Japanese destroyers, three West German destroyers, an Italian cruiser and seven Canadian destroyer escorts, as well as on cruisers, destroyers and escorts of the US Navy including the new "Spruance" class DD963 destroyers.

See also entry number **2507.231** for combined ASROC/Standard launcher in the Aegis system.

MANUFACTURER:

Prime Contractor: Honeywell Inc, 2701 Fourth Avenue, South Minneapolis, Minn. 55408.

RUSSIAN ANTI-SUBMARINE WEAPON SYSTEMS

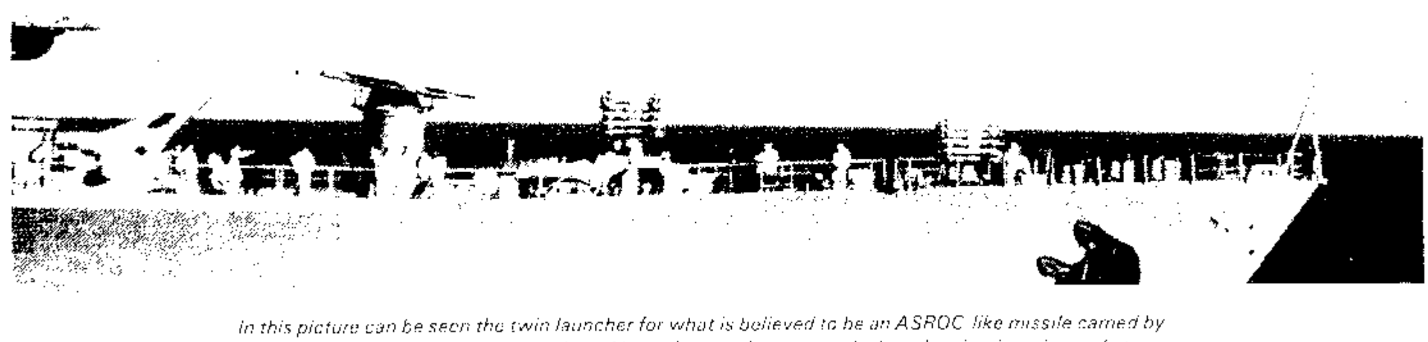
DESCRIPTION:

In general the development of anti-submarine weapon systems in the USSR closely parallels that which has occurred among Western nations. There has, however, been a time-lag between the two sets of developments, the Russians appear to have started serious developments of ASW systems other than simple depth charges only after the emergence of the nuclear-powered submarine in the West.

After making allowances for this phase-lag between the two programmes, the only major development of an ASW system for surface vessels that appears to have been omitted from the Russian programme is a drone torpedo system such as Ikara (**6002.241**) or Malafon (**1179.241**).

Some details of Russian anti-submarine mortars and rocket launchers will be found in Section 3 under entry number **6096.203**. It may be assumed with some confidence that these equipments are linked with sonars and fire control equipment to form a complete ASW system in much the same way as are the French or Swedish launchers (and others omitted from this section for lack of detailed information) described above (**2057.241** and **6021.241**).

Another system which is presumed to have a close Russian parallel is the American ASROC (**6001.241**). On the "Moskva" class helicopter carriers, there is a missile launcher forward of the two surface-to-air launchers (**2947.231**) which is widely believed to be for use with an anti-submarine missile of the ASROC type. No details are available.



In this picture can be seen the twin launcher for what is believed to be an ASROC like missile carried by the Moskva class helicopter carriers. Also to be seen here are multi-barrel anti submarine rocket launchers

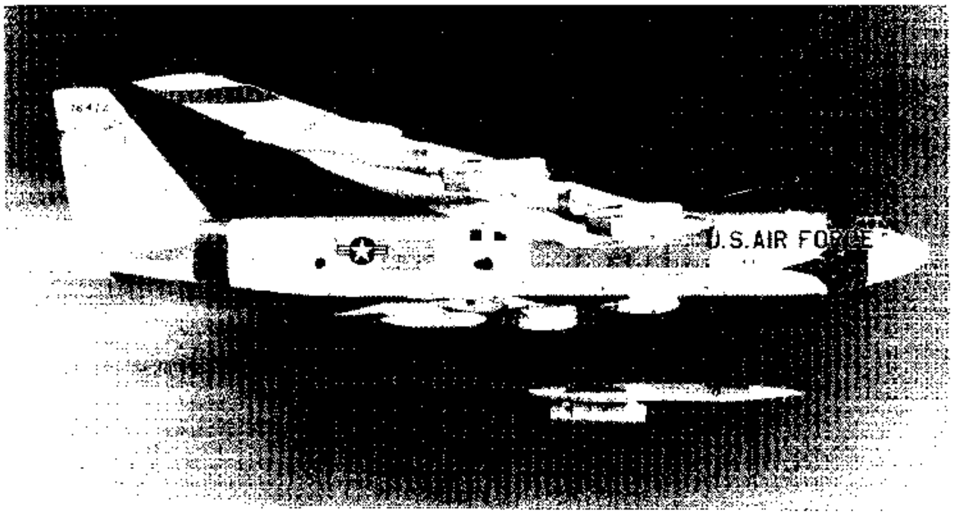
AIR-TO-SURFACE MISSILES—STRATEGIC

THE UNITED KINGDOM

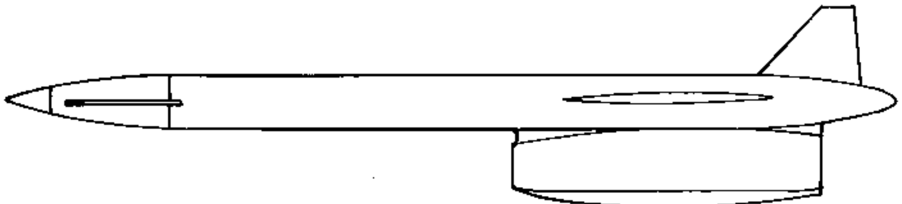
1078.311
BLUE STEEL STAND-OFF BOMB
DESCRIPTION:
Stand-off air-to-surface weapon designed for carriage as standard armament by the Mark 2 versions of the Vulcan and Victor aircraft of the Royal Air Force. It enables targets to be attacked from well outside the range of local defences. Its nuclear warhead is in the megaton range.
The missile has a rocket engine, using liquid propellants, which gives it a speed 'several times' the speed of sound at high altitude over very long ranges. After launching from the carrier aircraft it is guided to its target by an automatic built-in navigation system.
Blue Steel has small delta-shaped foreplanes for pitch control, a rear mounted delta wing with in-board ailerons, and a pair of stabilizing fins, the lower one of which folds sideways to give ground clearance.
Main dimensions of Blue Steel are: length 10.6 m, maximum diameter 1.72 m, wing-span 3.96 m, foreplane span 1.98 m. The airframe is mainly of stainless steel, and propulsion is by a two-chamber Bristol Siddeley Stentor liquid (HTP and kerosene) rocket motor. The inertial guidance system is by Elliott-Automation.
Range from release point has never been officially stated, but it is generally believed to be in the region of 320 km.
STATUS:
Entry into RAF service took place in the Summer of 1962, with Vulcan Mk2 aircraft of 617 Squadron. When the transfer of UK nuclear deterrent responsibility to the Royal Navy was announced, it was implied that Blue Steel was to be progressively withdrawn, but no subsequent official statement has been issued. It is assumed that some of these weapons are maintained on a 'care and maintenance' basis, and it has been reported that two squadrons of Vulcans are the only units still operating with this weapon.
MANUFACTURER:
Hawker Siddeley Dynamics Ltd, Manor Road, Hatfield, Herts, England.

THE UNITED STATES OF AMERICA

1093.311
HOUND DOG (AGM-28B AIR-TO-GROUND MISSILE
DESCRIPTION:
Long-range, stand-off air-to-ground strategic missile. Carried in pairs beneath the wings of USAF Strategic Air Command B-52 aircraft. Principal characteristics are: length 13 m, diameter 71 cm, height 2.83 m, span 3.66 m, range 960 km, speed slightly over Mach 2, weight 4,500 kg. It is powered by a Pratt & Whitney J52-P-3 turbojet air breathing engine, and the official ceiling is above 15,000 m. Nuclear warhead.
OPERATION:
The prime navigational mode of the Hound Dog missile from launch to target is an inertial navigation system INS developed by Rockwell International, Autonetics Division. Prior to launch, missile INS remain operative and are continuously updated by the navigation system of the parent B-52 and a Kollsman KS-140 astro tracking subsystem. The latter are housed in the pylon wing mount for each Hound Dog missile and their function is to provide continuous, high accuracy attitude and heading reference data for the missile inertial platforms.
The Hound Dog engines can be used to supplement those of the carrier B-52 to augment thrust at take-off or during cruise and the missile can be refuelled in the air from the aircraft tanks prior to release.
Missile targeting and mission profile can be varied by the B-52 crew in flight.
DEVELOPMENT:
Development was initiated by USAF Strategic Air Command in 1957, and the first launch took place in 1959. Entry into service under the original designation GAM-77A was in 1961. The AGM-28B (formerly GAM-77B) designation was allocated to an improved version, in which the principal modifications were aimed at increasing navigational reliability and accuracy. The programme was also known as Weapon System-131.
A project to incorporate a further navigational aid, TERCOM – Terrain Contour Matching – was subsequently dropped.



Hound Dog immediately after release from carrier B-52 strategic bomber



Hound Dog (AGM-28)

STATUS:
Hound Dog production ended in 1963. The USAF inventory of an estimated 600 missiles has since been the subject of refurbishing programmes under which Rockwell International has undertaken 'inspect and repair as necessary' action on large quantities. The AGM-28B is operational with USAF Strategic Air Command, and future deployment is dependent upon decisions taken by DoD concerning the future of the B-52 force and the development of other systems such as SRAM (which see). In March 1974 the US Secretary of Defence said that it had been decided to phase out Hound Dog with the B-52G/H force by Fiscal Year 1976.

MANUFACTURERS:
Rockwell International Corporation, 600 Grant Street, Pittsburgh, PA 15219, USA. Tulsa Division – prime contractor; Autonetics Division – inertial guidance system.
United Aircraft Corporation, Pratt & Whitney Aircraft Division, East Hartford, Connecticut, USA – engines.
Kollsman Instrument Company, Elmhurst 73, New York, USA – star tracker.

1766.311
ALCM AIR-LAUNCHED CRUISE MISSILE
DESCRIPTION:
The ALCM is the USAF portion of a joint endeavour with the US Navy to provide the former service with an advanced long-range strategic stand-off weapon and the Navy with a Submarine-Launched Cruise Missile. The latter would be produced in both tactical and strategic versions and is intended to be suitable for deployment on surface ships also. More details of the SLCM will be found in entry number **1759.411**.
The USAF will develop the ALCM as an adjunct to the strategic bomber force. The initial carrier will be the B-52 but ALCM will be used on the B-1 and could take advantage of that aircraft's improved pre-launch survivability characteristics. The ALCM programme will make maximum use of the now-cancelled SCAD (Subsonic Cruise Armed Decoy) engineering development programme for vehicle design and turbofan engine development. This design is particularly suited for launching from strategic bombers in that it can replace the SRAM (1107.311) on a one-for-one basis in both internal rotary racks and pylon mounts. This also suggests that the ALCM could be deployed with the FB-111 but official US defence sources have not named this aircraft as a possible carrier.
Both the ALCM and SLCM are seen as a major alternative approach to penetration of heavily defended Soviet targets. Cruise will be at sub-sonic speeds in the interests of maximum range. Guidance (overland) will be by the TERCOM (Terrain Comparison) technique which has been pioneered by the US Navy, and a terrain following system will be provided to enable penetration at a height

of a few hundred feet. It is anticipated that each missile will weigh about 2000 lb (900 kg).

DEVELOPMENT:

The USAF will concentrate on the development of a small turbo-fan engine for use on both the ALCM and SLCM. The USN will pursue development of the TERCOM guidance technology, which also will be common to both missiles. Present plans are that the USAF will commence engineering development of an ALCM in Fiscal Year 1975, and that this could be made available for initial deployment in the late 1970s. On this basis, the Fiscal Year 1975 Budget contained a sum of $80-million for the USAF RDT&E aspects of ALCM. For its part on the SLCM, the USN was allocated $45-million. Prime contractors nominated for the ALCM programme are the Boeing Aircraft Company for the airframe and carrier aircraft equipment, and Williams Research Corporation for the engine.

1767.311
AMX - AIRBORNE MISSILE X

DESCRIPTION:

Missile 'X' is the present designation given to a proposed USAF development for a new advanced mobile intercontinental ballistic missile system. Both land-based and airborne systems are being considered. Further information on the land-based and overall MX project will be found in entries **2707.111**, **2718.111**, and **2200.111** which precede this entry. The designation AMX refers to Airborne Missile X, which at this stage exists only as proposals put forward by industry. The salient features are outlined in the following paragraphs.

Boeing has suggested four approaches to the provision of a suitable airborne launch platform for the AMX. First is based on an adaptation of the Boeing 747 airliner, which would operate in conjunction with a tanker version of the same type of aircraft to provide the necessary payload/range characteristics. The carrier aircraft, MC-747 would have a missile payload of 180,000 kg in the form of four ICBMs of a new design and weighing about 45,000 kg each. An alternative load could be eight ICBMs of about half this size and weight. Boeing envisages a fleet of 36 MC-747s supported by 12 tanker 747s, with 25 MC-747s being at various stages of alert (including on station) at any one time. Launching would be by release from the aircraft followed by a stabilisation period, after which rocket ignition would take place to accelerate the missile into a ballistic trajectory to its target. Six methods of free-fall stabilisation have been studied: fins, an extendable skirt, nose ballast, canard surfaces, parachute(s) and thruster motors. The last two are apparently the most promising.

The other carrier aircraft possibilities put forward by Boeing are: (1) a new design four-engined land-based machine with a flight-refuelled performance of 15 hours with a 272,000 kg payload or 24 hours with 180,000 kg; (2) a land-based six-engined aircraft with wing-mounted missile pods to house the smaller version AMX and designed for long-endurance cruise; and (3) a high-wing amphibian with four engines and a payload of about 90,000 kg.

A major problem with the AMX concept is ensuring the high accuracy of navigational data, which is essential throughout the system if accuracy and reliability of delivery are to be assured. For the aircraft, inertial plus stellar, satellite, ground radio aids and area correlation for updating have been suggested, with inertial plus radio correction for AMX post-boost guidance and an unspecified form of terminal guidance.

STATUS:

The Fiscal Year 1974 allocation of funds to the MX project as a whole was $4.2 million, but in response to the appearance of the Soviet's four new ICBMs, SSX-16/17/18/19 and the SSN-8 SLBM, a big increase to $37.3 million for advanced studies and RDT&E was sought on behalf of MX in the Fiscal Year 1975 Budget.

1107.311
SRAM (AGM-69A) SHORT RANGE ATTACK MISSILE

DESCRIPTION

The Short Range Attack Missile (SRAM) is a supersonic air-to-surface nuclear weapon for the USAF, to complement and soon will replace the Hound Dog missile. It is being deployed with the B-52G and H, the FB-111, and the B-1 strategic bomber.

SRAM is designed to attack and neutralize enemy terminal defences, particularly the Soviet surface-to-air missile (SAM) defences. The weapon will have the capability of penetrating terminal defences and striking mission targets while the bombers stand off outside the range of enemy defences. It will also be able to attack enemy SAM and anti-aircraft sites so that bombers can strike primary targets with other SRAM or conventional bombs.

Other roles which have been considered include the use of the SRAM against airborne early warning and control aircraft, as an air-to-air missile, and as a defence against surface-to-air missiles. Boeing has said that the SRAM has the manoeuvre capability for air interception at relatively long range, and the General Dynamics anti-radiation detection and acquisition system for the standard ARM could be used in a version of SRAM.

The missile is 425 cm in length, 45 cm in diameter and weighs approximately 1000 kg. Range varies between 60 and 160 km, depending upon the flight profile employed, and a speed in excess of Mach 3 has been quoted.

The nuclear warhead carried is stated to be of the same size as that of the Minuteman 3.

An inertial guidance system is used, and the propulsion system is a two-pulse solid rocket motor developed by Lockheed. The first stage provides initial acceleration; the second stage is activated as the missile approaches its target. Trajectory can be changed in mid-flight, and the missile can be launched from any direction regardless of the bomber's flight path. The missile can be launched from either a high or low attack mode. The high mode is said to yield the greatest range but also increases the missile's vulnerability to enemy defences.

Four basic modes of flight trajectory can be employed: (1) semi-ballistic, (2) altimeter-controlled terrain following, (3) pull-up from behind radar screening terrain followed by inertial, and (4) a combination of inertial and terrain following. Lateral deviations in flight profile can also be programmed.

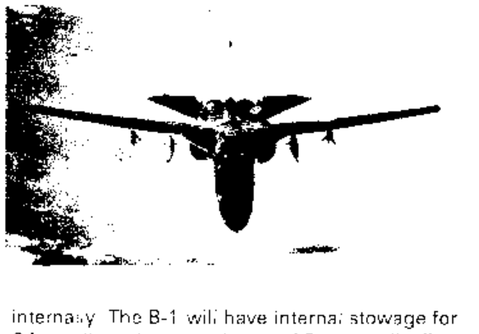
The B-52 carries twenty SRAMs, twelve of which are mounted in two clusters of three missiles on each wing, with eight more carried internally. The FB-111 can carry six missiles, four on individual pivoting pylons under the wings and two internally. The B-1 will have internal stowage for 24 missiles, plus a maximum of 8 externally. The rotary launcher to be used with SRAM on B-1 and B-52 aircraft will permit the launching of eight successive missiles at intervals of five seconds.

DEVELOPMENT:

Specific Operational Requirement 212 was de-

SRAM missile being launched from the internal weapons bay of an FB-111A aircraft at the White Sands Missile Range

SRAM (AGM-69)



FB-111A aircraft carrying SRAMs on wing pylons fined by the USAF in 1964, and requests for proposals were issued to manufacturers the following year. Boeing was selected as the prime contractor in October, 1966, for SRAM design, development and evaluation. The first dummy missile was dropped from a B-52 weapons bay on December 6, 1967. Missile guidance system tests were completed in February 1968. The first dummy drop from the FB-111 took place on November 19, 1968. B-52/SRAM navigation and guidance tests were conducted from Holloman Air Force Base Test Centre, and a simulated missile launch was accomplished in February 1969. By mid-1971 there had been sixteen launches from the FB-111, and flight tests were completed by July 1971, with the missile having exceeded specifications in range, accuracy, radar cross-section and reliability.

STATUS:

The first production SRAM was delivered to the USAF in March 1972. Contracts were placed for 101 missiles in Fiscal Year 1971, 465 in 1972, 480 in 1973 and 454 in 1974. Estimated unit costs for each batch are $760,000, $330,000, $268,000 and $209,000 respectively. It should be noted that these costs do not include the warheads, which are installed by the USAF. The USAF is to modify 282 B-52s and 72 FB-111 aircraft to carry SRAM, and deployment was started in the Summer of 1972 with deliveries of SRAMs to the 42nd Bomber Wing, Loring AFB, for SAC B-52s.

The 750th production missile was delivered in February 1974. The USAF has announced that by the end of 1975 a total of 1,500 would be produced. In March 1974 the US Secretary of Defence reported that acquisition of SRAM will be essentially completed with Fiscal Year 1974 funding and that the planned complement of operational missiles (1140) would be on hand by the mid-1970s.

MANUFACTURERS:

The Boeing Aerospace Company, PO Box 3999, Seattle, Washington 98124, USA – Main contractor.

Lockheed Propulsion Company, PO Box 111, Redlands, California 92373, USA – Solid-propellant motors.

Kearfott Division, General Precision, Inc., 1150 McBride Avenue, Little Falls, New Jersey 07424, USA – Inertial guidance sub-system (inertial platform, guidance and control electronics, guidance computer, power conditioner, rate gyros).

North American Rockwell Corporation, Autonetics Division – Aircraft computers, B-52, FB-111.

Litton Industries, Guidance and Controls Division – Inertial measurement unit B-52.

Delco Electronics – Missile computer.

Stewart-Warner, Electronics Division – Radar receivers/transmitter.

THE UNION OF SOVIET SOCIALIST REPUBLICS

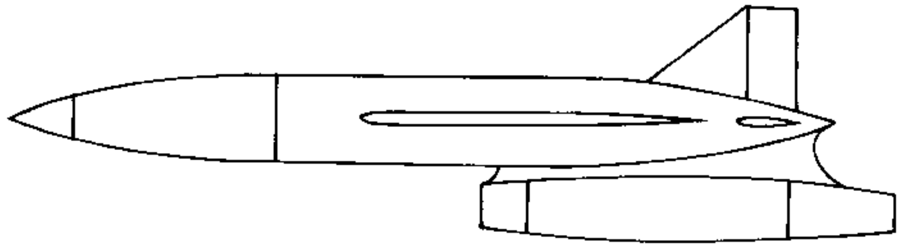
1150.311

KIPPER AIR-TO-SURFACE MISSILE (AS-2)

DESCRIPTION:

Kipper is the NATO code-name of another Soviet stand-off missile, which with Kangaroo (Entry No. **1147.311**) was first seen in 1961. Somewhat smaller, approximately 9.5 m in length and with a wing span of about 4.6 m, it also has an aircraft-like configuration with swept wing and tail surfaces. Propulsion is by a turbojet motor suspended beneath the missile fuselage. Most Western estimates of Kipper's range give a value of between 180 and 210 km. In general appearance Kipper resembles the American Hound Dog, AGM-28 (Entry No. **1093.311**), stand-off strategic bomber weapon.

Kipper is generally considered by observers in the West to be essentially an anti-shipping missile, but the possibility that it may be used for strategic bombing of land targets should not be completely discounted. The weapon is associated with the Tu-16 Badger-C bomber aircraft.



Kipper (AS-2) Provisional

Kipper stand-off missile mounted on Tu-16 Badger-B bomber aircraft

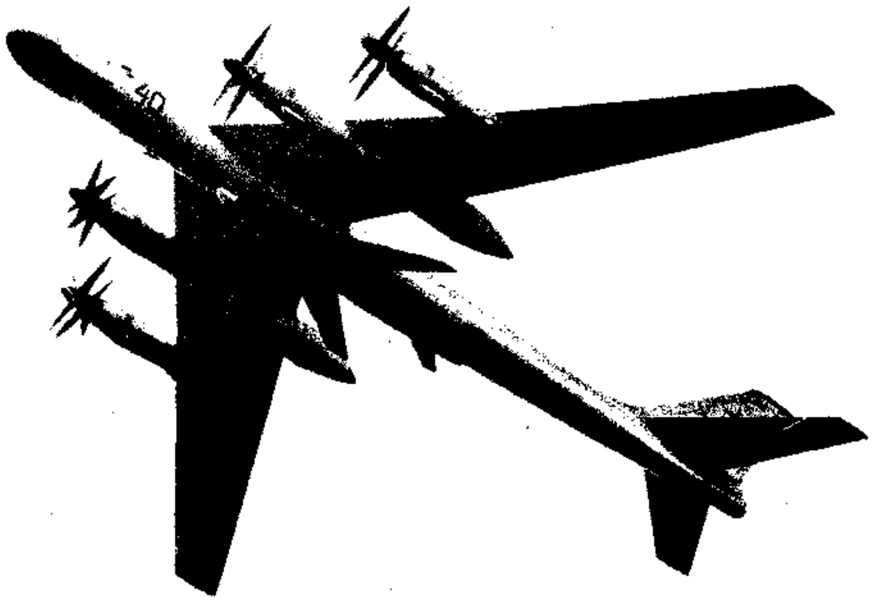
1147.311

KANGAROO AIR-TO-SURFACE MISSILE (AS-3)

DESCRIPTION:

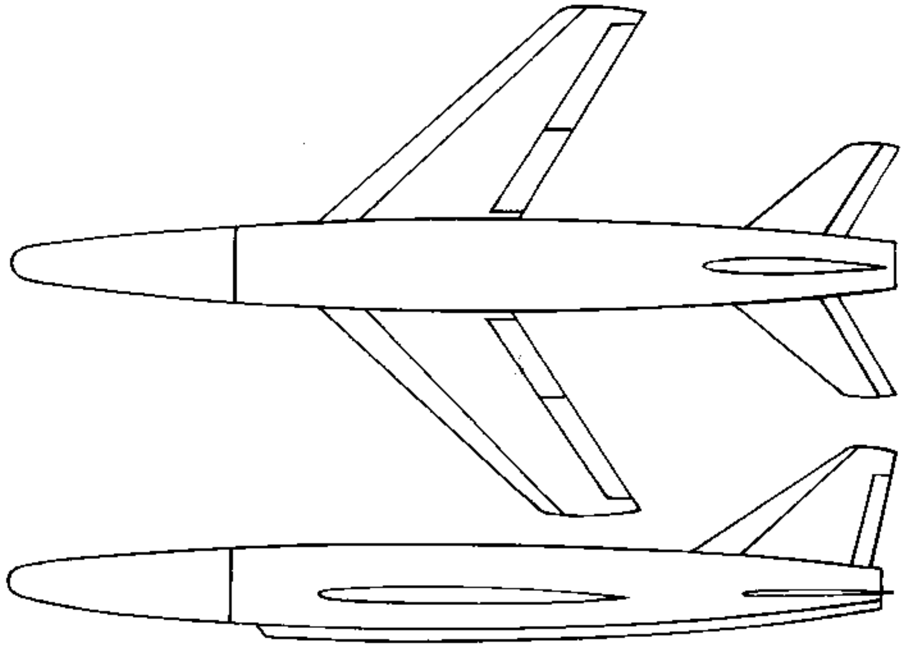
Kangaroo is the NATO code-name assigned to the largest Soviet air-to-surface missile so far revealed. First shown in public in 1961, it is associated with the Tu-95 Bear bomber aircraft and is generally assumed to have retained operational status though its operational importance has probably declined significantly as newer weapons have been deployed.

As the photograph shows, the Kangaroo has the configuration of a conventional swept-wing fighter aircraft and similar dimensions, approximately 15 m in length and with a span of 9 m. The propulsion used has not been confirmed but is probably a turbojet engine. There is no reliable information available as to the ratio in which the relatively large payload potential of Kangaroo is allocated between range and warhead, as is borne out by the wide variation in range estimates published by different specialist sources. These extend from 185 km to 650 km, and it is likely that all these ranges are possible but without access to trustworthy data of the type and weight of warhead,



Kangaroo stand-off missile beneath Tu-95 Bear bomber aircraft guidance method(s) and performance, the true range figure must remain conjecture.

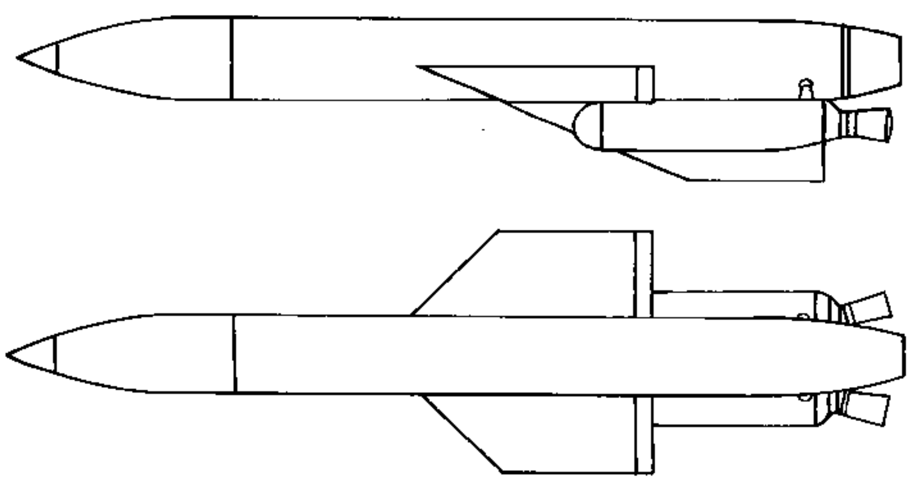
Similar considerations apply to Kangaroo's military function, but the most probable is that the weapon was designed as a medium/long-range stand-off nuclear weapon for use against 'area' targets, such as cities or industrial areas, rather than point targets.



Kangaroo (AS-3) Provisional

1151.311
KITCHEN AIR-TO-SURFACE MISSILE (AS-4)
DESCRIPTION:

Kitchen appears to be one of the most technically advanced Soviet air-to-surface missiles yet revealed. It has a fuselage about 11 metres long to which are attached a pair of delta platform wings and a cruciform tail assembly. Propulsion is by rocket motor, liquid-fuel burning according to American sources, and inertial guidance is assumed. Estimates of range vary widely from 300 km to 800 km, and the aerodynamic features of Kitchen suggest a high cruising speed. The only Soviet aircraft type known to be equipped to carry this weapon is the Tu-22 Blinder, beneath which it was first seen in 1967. The missile is carried in a partly enclosed position on the fuselage undersurface.



Kitchen (AS-4) Provisional

AIR-TO-SURFACE MISSILES—TACTICAL

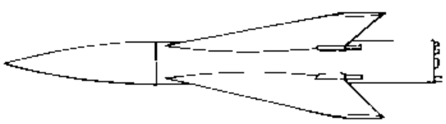
FRANCE

1170.311
AS.20 AIR-TO-SURFACE MISSILE
DESCRIPTION:

Supersonic air-to-surface tactical missile, powered by a two-stage (booster and sustainer) propulsion system. The AS-20 uses solid fuel motors. Principal characteristics are:– length 259 cm, diameter 25 cm, wing span 78 cm, weight 143 kg. A conventional high explosive warhead weighing 30 kg is carried, and a direct action fuse is fitted. The booster motor stage exhausts through two slightly divergent nozzles, and the sustainer uses a single nozzle which is fitted with vanes that enable the missile to be steered. Estimated speed is Mach 1.7 and the approximate flight time is 16 seconds.

OPERATION:

Radio command guidance is used to direct and steer the AS.20 to the target, and the rear of the missile carries twin flares to aid tracking. The same system of control that is used for the AS.30 missile (which see) can also be used for the AS.20, and the latter weapon is proposed by the manufacturers for use as a training round for AS.30 operation. A special adaptor is available to enable the AS.20 to be carried by aircraft normally equipped for the AS.30. Launch of the AS 20 is possible from any aircraft capable of a speed of Mach 0.7 or over.



AS.20

The standard fire control equipment for aircraft using the AS.20 consists of: command guidance installation, including control stick; command radio transmitter, with optional co-ordinate converter; ignition and power supply circuits; and missile launchers with three missile attachment points, mounted either under the fuselage or wing.

STATUS:

The AS.20 has been ordered in quantity by several armed forces, and it is estimated that at least 8,000 have already been supplied. Users include the French Air Force and Navy, the German and Italian Air Forces, and at least two other countries.

MANUFACTURERS:

Société Nationale Industrielle Aérospatiale, Division Engins Tactique, 2 rue Béranger, 92320-Chatillon, France.

1171.311
AS.30 AIR-TO-SURFACE MISSILE
DESCRIPTION:

Medium/heavy air-to-surface tactical missile. The AS.30 has been described as a scaled-up AS.20, and the general configuration and mode of operation are very similar. The AS.30 has a streamlined, cylindrical body with swept cruciform wings. Early versions of this missile appeared without any other surfaces, but current models also have four small fins very near the rear end of the missile and located between the exhaust tubes of the booster motor.

Principal characteristics of the AS.30 are:– length 390 cm, diameter 34 cm, wing span 1 m, weight 520 kg. Weight of the high explosive warhead is 230 kg. Speed at impact is 450-500 m/sec. and range is 10 to 12 km. Propulsion is by two-stage solid-fuel motors, booster and sustainer.

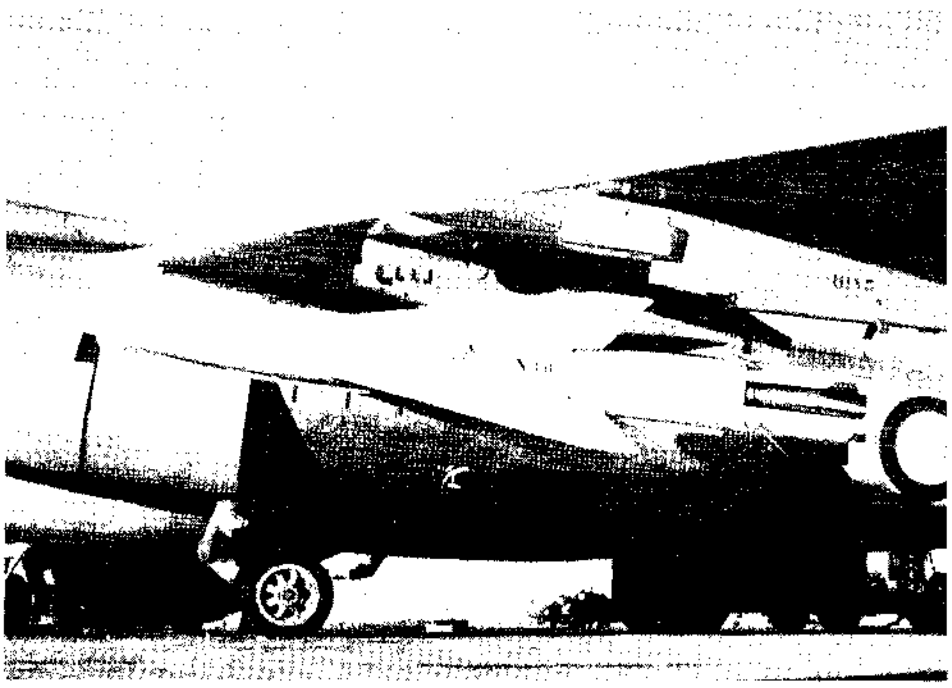
OPERATION:

Guidance is by radio command link, with two alternative methods of control from the launch aircraft. The simplest is the use of a control stick in the cockpit of the launching aircraft with which the operator controls the flight of the missile to the target by visual observation of its flight path. Flares are fitted to the missile to aid tracking. A later development uses a stabilised IR tracker on the aircraft and infra-red flares on the missile to provide a form of automatic guidance.

On the aircraft an infra-red tracker developed by Société Anonyme de Télécommunications provides continuous data on the missile position relative to the aircraft, while the pilot uses his attack sight to provide a continuous bearing to the target. This is accomplished by merely keeping the target centred on the aiming mark of the sight. An on-board computer unit uses these data to derive corrective command signals which are transmitted to the missile guidance system in the same way as for manually controlled firing of the AS.30.

The radio command link is of the progressive type, and in the normal (manual) mode of operation, it continuously transmits pitch and yaw demand signals which originate from movements of the two-degree-of-freedom control stick in the cockpit of the launching aircraft.

An ingenious operational mode possible with the AS.30 in tactical attack situations where the target is relatively large and a rather greater CEP can be accepted involves the use of two aircraft. The first approaches the target, followed by the second aircraft some kilometres astern, and launches the missile toward the target. The launch aircraft then immediately breaks off and takes evasive action, leaving the second aircraft to assume command of the missile from a safer distance. To meet this requirement, a three-position commutator switch is provided with positions for firing with guidance; firing without guidance, and guidance without firing. The first position corresponds with normal use of the missile by a single aircraft, and the second and third positions inhibit the command transmitter and the missile firing circuits, respectively.



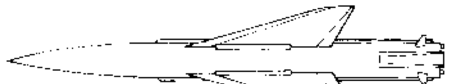
AS.30 air-to-surface missile

DEVELOPMENT:

The AS.30 was designed and developed to meet a specification by the French authorities which called for a minimum launch range from the target of 10 km and a further requirement that the aircraft would not need to come within 3 km of the target. A circular probability error of 10 m or less was also specified, and it is reported that these requirements have been exceeded in use. Compared with the AS.20, the larger AS.30 is capable of launch at a lower speed – Mach 0.45 compared with Mach 0.7.

STATUS:

The AS.30 is in full production and orders outstanding or completed are estimated to exceed 8,000. Users in addition to the French Forces include: The RAF, German, Indian, Israeli, Swiss and South African air forces.



AS.30

MANUFACTURERS:

Société Nationale Industrielle Aérospatiale, Division Engins Tactique, 2 rue Béranger, 92320-Chatillon, France.

1173.311

AS.11 AIR-TO-SURFACE MISSILE

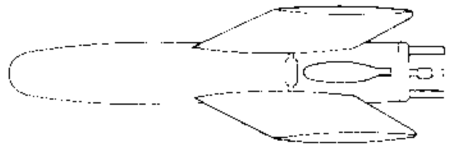
DESCRIPTION:

Wire-guided multi-purpose, lightweight air-to-surface missile. The SS-11 was originally conceived as a general-purpose battlefield weapon for deployment on surface vehicles, but it has been successfully adapted for use with helicopters, hovercraft and surface vessels. Designation of the former version is AS.11.

Principal characteristics are: length 1.2 m, diameter 16.4 cm, wing span 50 cm, weight 29.9 kg (approx). Average cruising speed is 160 m/sec, and time of flight 20 to 21 seconds. The maximum practical range is 3,000 m. The SS.11 B1 can be equipped with three types of warhead, anti-tank, a 'high-effect' high explosive warhead, or fragmentation type.

OPERATION:

Using a stabilised optical sight, the operator gathers the missile after launch (aided by tracer flares attached to the missile), and then uses a control stick to transmit command signals to the missile via wires to align the missile flight path with the target. Maintaining this alignment results in the missile hitting the target.



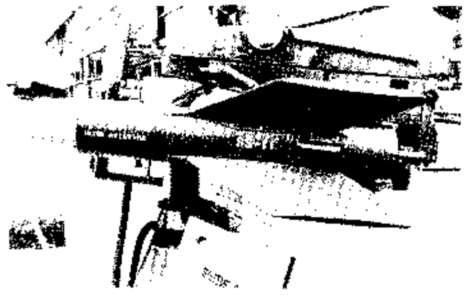
AS.11

STATUS:

Between 100,000 and 200,000 of the various versions of the SS.11 series have been supplied to 21 different countries.

MANUFACTURERS:

Société Nationale Industrielle Aérospatiale, Division Engins Tactique, 2 rue Béranger, 92320-Chatillon, France.



The SS.11 shown on a surface launch mounting. The airborne missile is virtually identical

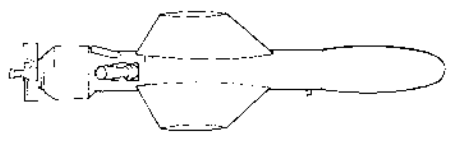
---

1174.311

AS.12 AIR-TO-SURFACE MISSILE

DESCRIPTION:

Airborne version of the SS.12 (which see) to provide an air-to-surface general-purpose lightweight missile. Principal characteristics are: length 187 cm, warhead diameter 21 cm, wing span 65 cm, launch weight 76 kg, weight of warhead 28.4 kg. The AS.12 can be equipped with a variety of different warheads to meet a range of operational requirements. The OP.3C has penetrating power sufficient to pierce over 40 mm of armour plate with a delayed action detonation, and other types include a powerful shaped charge, and a fragmentation head.



AS.12

OPERATION:

Guidance is by command signals fed to the

Close up of AS.12 missile

missile via wires, the missile operator in the aircraft usually being provided with a stabilised sighting system, and a control stick for steering the missile. Installed in a helicopter, the AS.12 is reported to be highly accurate when used with such a sight at ranges out to 6,000 m. Use of a sight of this type also permits the launch aircraft to manoeuvre during missile flight. Maximum range of the AS.12 when launched from an aircraft providing 200 knots forward speed is 8,000 m.

DEVELOPMENT:

While the SS.12 and AS.12 are based on the highly successful techniques employed in the earlier SS.11 series of missiles the former weapons have been designed with much greater versatility and kill power in view. Range is approximately doubled, and the warhead is stated to be four times as powerful as that of the SS.11. The SS.12 range of missiles is capable of being launched from the several types of launcher developed for the SS.11 missiles.

STATUS:

The AS.12 is in operational service with at least eight different types of aircraft, including the ASW Atlantic and Nimrod aircraft and RN Wasp and Wessex helicopters.

AS.12 air-to-surface missile carried by Wasp helicopter

AIR-LAUNCH EXOCET (AM.38 & AM.39)

DESCRIPTION:

The successful MM.38 Exocet anti-ship missile has had its usefulness increased by the development of two air-launched versions, the AM.38 and AM.39. The former is a virtually standard Exocet missile slightly modified to enable it to be launched from beneath the Super-Frelon naval helicopter instead of from a launcher container as in the shipborne version (**1156.221**). The AM.39 model has slightly more extensive changes to permit its deployment on fixed-wing aircraft which may operate at greater altitudes than the Super-Frelon.

The Super-Frelon/Exocet weapon system comprises:

(1) An Omera ORB-31D search radar which incorporates facilities for the automatic transmission to the missile to be fired continuous target range and bearing data. The target is designated on the radar by the operator.

(2) A control panel for the insertion of operational information.

(3) A missile adaptor kit which provides for missile selection and also performs pre-launch navigation calculations for the selected missile.

(4) Two missile launchers located alongside the helicopter fuselage, ahead of the main landing wheels.

Equipped in this way the Super-Frelon can carry 5,000 litres of fuel, by means of extra tanks, enabling it to remain airborne for about six hours, or engage a target up to 350 nautical miles away. The main characteristics of the missile in this role are: range 28 nautical miles; inertial cruise followed by active radar homing; sea-skimming cruise, impact or proximity fuse. The missile is released from the helicopter inert, the motor being ignited 1.5 seconds later.

Super-Frelon carrying two AM.38 air-launch Exocet anti-ship missiles

The high-altitude, fixed-wing aircraft version of Exocet, AM.39, has been evolved with deployment on Atlantic and Super-Etendard aircraft in mind.

DEVELOPMENT:

Following the release of three inert models from a Super-Frelon, two Exocets were launched in June 1973 with motors that had had their burning time limited to reduce the distance covered by these test pieces. These tests were successful and were later followed by more elaborate trials involving the helicopter firing installation and the ORB-31-D radar.

STATUS:

The French Government is understood to have decided on procurement of the AM.38, but at May 1974 no decision on the AM.39 version had been disclosed.

GERMANY (FEDERAL REPUBLIC)

1180.321
KORMORAN AIR-TO-SURFACE ANTI-SHIPPING MISSILE

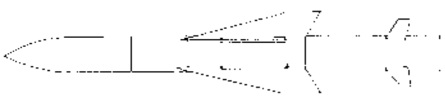
DESCRIPTION:

Kormoran (AS.34) is an advanced air-to-surface missile, designed principally for strikes against surface shipping. The guidance system employed provides a useful stand-off capability for the launch aircraft. Main characteristics of the missile are length 440 cm, diameter 34.2 cm, wing span 1 m, weight 580 kg, speed Mach 0.95, and range about 20 nm.

Propulsion is by solid-fuel motors, and a hybrid guidance system is employed. Cruciform, broad chord swept wings are located just aft of the cylindrical missile body midpoint, and these are followed by a set of four in line tail fins. A specially-developed high explosive warhead is carried.

OPERATION:

Several operational modes appear to be provided for by the guidance equipment developed for the Kormoran. The major portion of the trajectory is travelled under the guidance of an inertial system followed by a terminal homing phase on to the target. The latter phase can be performed by one of three methods, passive infra-red, active radar homing, or passive homing on to radiation from the target itself.



Kormoran (AS.34)

Target designation could be performed by either the radar of a surface vessel working in conjunction with the Kormoran carrying aircraft, or with the aid of the latter's forward radar. A completely blind attack also seems possible, provided the geographical co-ordinates of the target are known to reasonable accuracy.

Missile launch, according to information released at the 1969 Paris Air Show, is normally effected from a low level, with the aircraft flying in the general direction of the target. On release, the first of the two propellant motors burns for about one second to accelerate the missile, after which the single-nozzle sustainer motor takes over. There is presumably on-board computation equipment to relate the precise position of the aircraft at the time of launch with that of the target to enable the missile inertial navigation system to guide the missile toward the target at low level to remain beneath radar cover for as long as possible.

At a predetermined position, a climb is programmed to take the missile up to a height from which the target can be 'seen' to enable the homing equipment to take over for the terminal phase of the attack.

The radar homing head fitted is the RE 576 developed by Thomson-CSF. This is stated to be capable of either active or passive homing, and the assumed mode of operation is that when the missile has reached a height to bring it within line-of-sight range of the target, the radar receiver is switched on for an initial period during which it searches for radar signals emanating from the target. If such signals are received, the homing head will lock on and the missile will operate in a passive homing mode. In the absence of signals, the radar transmitter in the missile will be switched on and a target search, lock on and tracking sequence will follow to enable the missile to intercept the target.

The RE 576 head is an autonomous automatic search and track radar, providing range, bearing and elevation data from which control signals for the missile autopilot can be derived. An inverse-Cassegrain aerial system is used, with the feed passing through the centre of a ridged-plate main reflector. Energy from the feed is first directed to a semi-reflector situated in front of the gimballed reflector plate, before being returned to the latter which is responsible for focusing and steering the beam.

DEVELOPMENT:

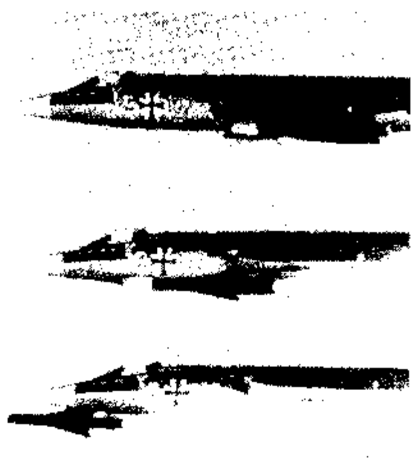
Kormoran is the largest missile project so far undertaken in West Germany, and was initiated in 1964 to meet a Navy requirement. Messerschmitt-Bolkow and SNIAS are working in collaboration on the project. The inertial navigation system is most probably the same as that flown in the Nord experimental AS.33 missile. The RE 576 was stated by the manufacturers to have achieved 120 experimental launches by June 1969, and the same unit is believed to be employed in the Swedish anti-shipping missile.

STATUS:

The first air launch, from an F-104G, took place successfully on March 19, 1970.

In May 1971 it was announced that the first of a series of fully equipped missiles had been successfully launched from an F-104G against a moving target 'many kilometres' away. The homing head successfully acquired and tracked the target. No warhead was used for this test.

Further prototype firings were followed by deliveries for armament evaluation tests by the West German Navy in the Summer of 1972. These trials had been completed successfully by early 1974 and preparations for serial manufacture were then in progress.



MBB Kormoran launch sequence from W German F-104G during operational tests over the Bay of Biscay. Hits were scored on a target ship at maximum range and with a head-on aspect

So far the West German Navy is the only named user for the Kormoran, but interest from the Italian Air Force has been reported, and use with the MRCA is another possibility.

JUMBO AIR-TO-SURFACE MISSILE

DESCRIPTION:

Jumbo is a large, long-range stand-off air-to-surface missile being developed by Messerschmitt-Bölkow-Blohm GmbH under contract to the Federal Ministry of Defence. It is intended for use against large or high-value surface targets, and it is proposed to deploy this missile with the MRCA and F-4 Phantom aircraft. Dimensions are: length 5.24m, diameter 50 cm, span 1.25m, and weight approximately 1150 kg. Guidance during the cruise phase will be by autopilot/inertial system, with TV target aquisition and homing for the terminal phase. The crew of the launching aircraft will be provided with a monitor screen for viewing the television pictures relayed via a telemetry link from the Jumbo missile.

The complete system consists of the missile itself and an electronics package which will be carried by the aircraft as an external store, thus eliminating the need of a large, permanent installation inside the aircraft. It also enables the Jumbo system to be adapted to various aircraft types.

DEVELOPMENT:

Jumbo is under development by MBB under a West German Ministry of Defence contract. There is a possibility that the programme may eventually become an international project according to MBB.

The first picture to be released of the MBB Jumbo stand-off missile.

MANUFACTURER:

Messerschmitt-Bölkow-Blohm GmbH, Munich-Ottobrun, West Germany.

1531.311

STREBO AIR-TO-SURFACE AREA WEAPONS

DESCRIPTION:

The STREBO designation has been given to studies by Messerschmitt-Bölkow-Blohm of weapon systems specifically to counter large-scale ground attacks by infantry and armour. Two versions had been identified by May 1972, Strebo I and Strebo II. The former is proposed for deployment on West German F-104G aircraft, while Strebo II is larger and is intended for carriage by the MRCA. The Strebo classification apparently refers to weapon dispensing systems and techniques rather than missiles. It is envisaged that bomblets (with and without delayed action fusing) and mines would both be employed, with distribution by 'seeding' and assisted dispersion methods. The latter would include rocket assistance to initially launch the weapons above the sending aircraft to ensure distribution over a greater area. The aircraft would operate at very low level. The weapons would be suitable for both anti-personnel and anti-tank use, and mixed payloads would be carried.

STATUS:

No official information has been released but it is reported that the first of these weapons could be ready by the mid-1970s.

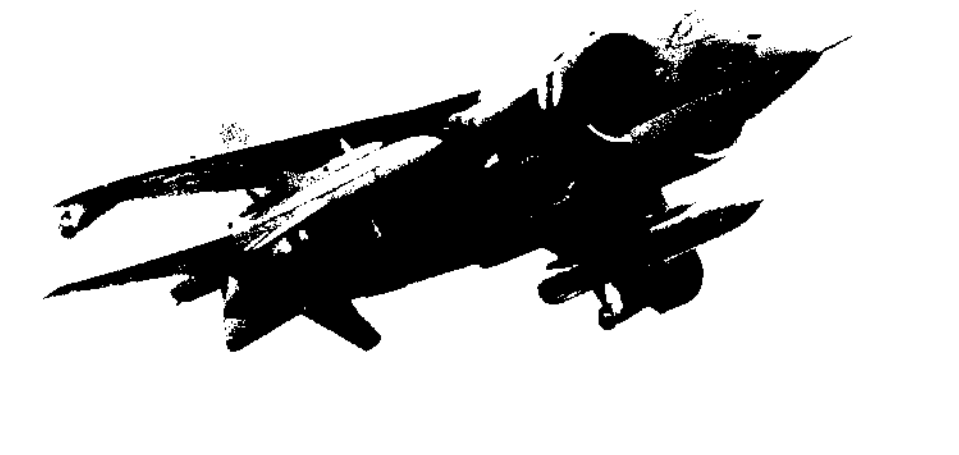
INTERNATIONAL

1022.311

MARTEL AS.37/AJ.168 AIR-TO-SURFACE MISSILE

DESCRIPTION:

Martel is an air-to-surface tactical missile with two alternative terminal guidance systems capable of offering a considerable stand-off capability. Both versions are designed to operate in an ECM environment, to which a high resistance is claimed. The two forms of terminal guidance are: passive homing onto electromagnetic radiation in the AS.37, anti-radar version; and visual guidance to a selected target by means of a nose-mounted TV camera and a data link over which both video and command signals are passed be-



Hawker Harrier carrying anti-radar versions of Martel missile tween aircraft and missile, in the AJ.168 variant. The Martel system is the product of a joint Anglo/French development programme with prime responsibility for the AS 37 resting with Engins Matra, and for the AJ.168 with Hawker Siddeley Dynamics.

General configuration of the missiles can be seen from the diagram and adjacent photographs. Length of the AJ.168 is 390 cm, and of the AS.37, 420 cm; body diameter and wingspan, respectively, for both versions are 40 cm and 120 cm. No details of performance have been revealed, but range has been officially stated both as 'several tens of miles' and several 'tens of kilometres'. This suggests a range of about 60 km although maximum range will be to some extent dependent upon the height of launch and subsequent trajectory.

OPERATION:

Both versions of Martel probably employ the same basic autopilot which provides guidance until either TV or radar homing systems assume control for the terminal guidance phase. There are some indications that the autopilot can be pre-programmed to provide several options of mission profile. A fundamental difference, in addition to the guidance system, is related to the two-stage propulsion assembly, which is adapted to the mission requirements specific to each version.

Martel AS 37. The Electronique Marcel Dassault AD.37 homing head is believed to use a movable receiver aerial, possibly of the inverse Cassegrain type, and this is used both prior and subsequent to launch from the aircraft. Prior to launch, the AD 37 provides data for the pilot for navigation to and determination of launch point. These data are presented via the aircraft equipment, and probably consist of initial warning of hostile radar signals, followed by information on their aspect relative to the aircraft. After launch, the AD.37 head locks onto the radar target and generates guidance signals for the auto-pilot to direct the missiles to the target. Missile control is by means of four moveable fins placed a short distance behind the cruciform wings.

Martel AJ.168. Where illumination by the opposing radar is necessary for the AS 37 version of Martel to operate, the TV-guided variant will most likely be deployed and operated to keep radar contact to a minimum, and for this reason it is more likely to be launched from a low altitude, preferably while the launch aircraft itself is still beyond radar range. Launch will be from a known geographical position and the weapon will be directed along a calculated track to the target.

A TV camera in the nose will produce pictures of the terrain over which it is flying, and these are transmitted back to the missile operator in the launch aircraft, which by this time can be on its way back to base. A monitor screen in the operator's cockpit will enable him to relate the missile track to the correct calculated path, enabling him to make corrections. He may be aided in this by a projected map display. When the designated target (or a target of opportunity) is sighted by the TV camera, the operator can use the radio command link to fly to it, completing the attack.

The TV Camera Control Unit and the Video and Command data link system have been developed by Marconi Elliott Avionic Systems Ltd.

DEVELOPMENT:

The UK and France entered into an agreement for the joint development and production of Martel in September, 1964, although related studies preceded this by possibly as much as four years. The first simulated firings and mock-up launchings took place in the Summer of 1964, and prototypes of both versions were completed in 1965-66. Evaluation trials have been completed for both variants.

STATUS:

Production contracts were placed by the British and French Governments in December 1968 and production missiles and equipment are now being delivered to the British and French Services. The Martel system will be used on the Mirage III E, Jaguar, Atlantic, and Buccaneer Mk II.

1338.321
OTOMAT ANTI-SHIP MISSILE (FRANCE/ITALY)

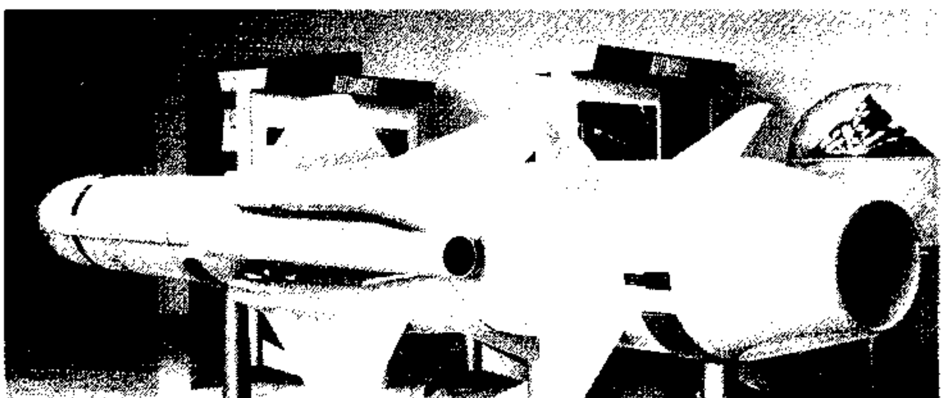
DESCRIPTION:

Otomat is the anti-surface version of an all-platforms anti-ship missile. Range is over 80 km, but with fuel capacity for greater ranges (200 km); speed is in the region of Mach 1. Inertial guidance plus a radio altimeter is used for the low-level cruise phase with a Thomson-CSF active homing head for terminal guidance. Two lateral boosters are employed for initial acceleration in the helicopter version but these are not always required for the aircraft version. A more detailed description appears in Entry No **1336.221**.

DEVELOPMENT:

Studies are underway for the adaptation of Otomat to other aircraft. A series of completely guided firings has been made so far to demonstrate and evaluate the long range capability, and the shape of the final attack pattern.

Development continued until 1974, will be followed by evaluation by the Italian Navy, which has already signed a contract for the surface-to-surface version.



Air-to-surface version of the Otomat anti-ship missile

STATUS:

The use of Otomat for its maritime patrol aircraft (Atlantic) and its strike aircraft (Super Etendard) is under consideration by the French Navy. The missile is also proposed for helicopters (SH-3D, and Superfrelon).

MANUFACTURERS:

Engins Matra, 78140 Vélizy, France.

1771.311
HOT AIR-TO-SURFACE MISSILE
DESCRIPTION:

The relatively recent increase in interest regarding the use of helicopters in a specifically anti-tank role has led to the development of a helicopter installation for the HOT anti-tank weapon. The basic HOT missile is described in Entry No. **2212.111** in an earlier section of this book, and the following refers to the helicopter version.

Depending upon the type of helicopter used, two, four or six launcher ramps to accept the HOT combined container-launch-tube can be fitted, and these are elevation-slaved to the line-of-sight. For helicopter operation a stabilised optical sighting system is used, this being derived from the APX334 sight described in Entry No. **7032.393** in Section Three of this book.

The guidance system includes a dual-field infra-red 'localizer', with a 12-degree acquisition field and a one-degree tracking field. The function of the infra-red localizer is to establish the position of the HOT missile relative to the line-of-sight (which normally will be maintained on target by the operator using his optical sight). Appropriate guidance signals are computed and transmitted via the command wire to maintain the missile on the line-of-sight to the target.

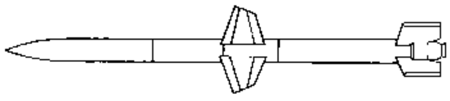
1650.321
AIRTOS AIR-TO-SURFACE ANTI-SHIP MISSILE
DESCRIPTION:

Airtos is an aircraft-launched anti-ship missile for use at short to medium ranges and under all-weather conditions. The design provides for the engagement of high-speed (up to 90 knots) targets such as hydrofoils and hovercraft with considerable manoeuvring capabilities. The principal dimensions of Airtos are: length 3.9 m, body diameter 206 mm, wing span 857 mm, weight (at launch) 191 kg. The maximum speed is Mach 1.9, maximum launch range is 11 km, and the minimum range from an aircraft at 500 m is 3 km. A 35 kg fragmentation warhead is carried and impact and proximity fusing are provided. The solid propellant booster motor has a thrust of 2,000 kg and a burning time of five seconds. Aerodynamic control is by means of the four moveable cruciform in-line wings, and stability is assisted by a set of four tail fins. Active pulse radar guidance is used, assisted by a radio altimeter.

OPERATION:

The launching aircraft can use any means for surface target detection, after which the Airtos missile is directed towards the target by aircraft manoeuvres. When homing head lock-on to the target has been achieved (between 17km and 11 km) the operator is warned and the missile can be launched. After launch, no further guidance of Airtos is required from the aircraft which is then free to take avoiding action or engage other targets. Shortly after release from the aircraft the missile drops to a cruise altitude of about 10 metres which is maintained under radio altimeter control. At a preset distance from the target, altitude is further reduced to 2 to 5 metres for the final



Airtos

attack phase. Throughout the missile flight homing guidance is by means of the active radar homing system. This system has an antenna angular aperture of 30 degrees, and high resistance to sea and rain clutter.

DEVELOPMENT:

Development is believed to have started in 1969 and the Airtos system was still in development during 1974.

MANUFACTURER:

SISTEL – Sistemi Elettronici S.p.A., Via Tiburtina 1210, 00131 Rome, Italy.

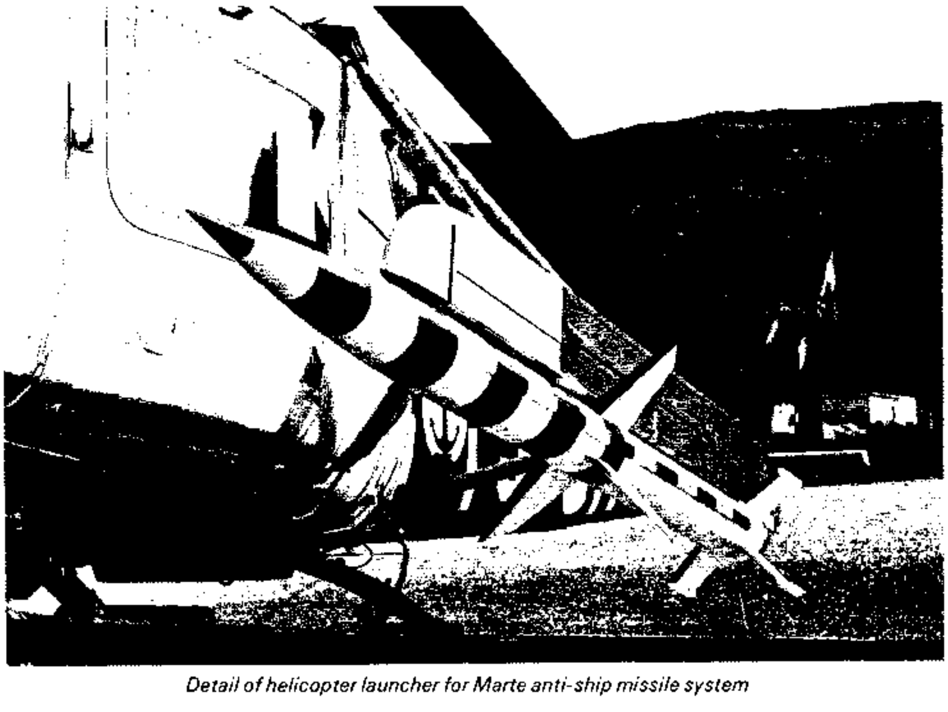
1651.321
MARTE HELICOPTER ANTI-SHIP MISSILE SYSTEM
DESCRIPTION:

The purpose of the Marte system is the destruction or disabling of naval craft in "all weather" conditions by means of Sea Killer missiles launched from helicopters in a stand-off position.

So far, the helicopter-borne missiles used in conjunction with the Marte Project are the Sea Killer Mk1 (10 km range with 35 kg warhead) and Sea Killer Mk2 (20 km range with 70 kg warhead for the Marte version). Easily operated and light equipment only need be carried on board the helicopter since the radar performs navigation search and track of the target as well as guidance of the missile in azimuth (the missiles are autonomous in altitude by means of SISTEL-designed radar altimeter).

Installation of the Marte Weapon System has been studied on helicopters ranging from a maximum TO weight of 3,000 kg up to 10,000 kg or more depending on the number of missiles carried and on the operational requirements which may call for simultaneous ASW and Surface Strike capability or not.

A typical installation is pictured in the nearby diagram: the SH3D helicopter shown, fully equipped for Surface Strike and anti-submarine surveillance plus autopilot for instrument flight.



Detail of helicopter launcher for Marte anti-ship missile system can be assigned to a 4.30 hour patrol mission, at a search speed of 100 knots (max. 130) with a crew of 4.

The Sea Killer Mk1 and Mk2 are sea-skimmer missiles, of a cruciform configuration and centre wing control, roll-stabilized, and based on the use of a combined radar (illumination) radio command/radio altimeter guidance system. For the configurations studied for the Italian Navy, two Sea Killer Mk1 missiles have been installed on light helicopters, and alternatively two Sea Killer Mk2 or four Sea Killer Mk1 on-board heavier ones, always allowing for at least a 4 hour endurance.

OPERATION:

Figure 2 shows the events occurring in the case of a helicopter attack on a naval target with a Sea Killer Mk2 missile. The helicopter discovers a target with a short radar exposure time: a few seconds. It may be assumed that detection occurs at the radar range limit; in these conditions the probability that the enemy recognizes the helicopter's radar interrogation is not absolutely certain; the helicopter, therefore, having discovered the target, shuts down its radar, reduces altitude to elude as far as possible the enemy's active search and, with dead reckoning or with a passive "homing" procedure on radar interception directs itself towards the target. At an estimated distance slightly above the missile range, it rises again to the launching height, re-acquires the target and launches the missile which takes slightly more than a minute to reach the target. It is not necessary for the helicopter, having launched the first missile, to proceed en route towards the target, it may as well hover or change course and altitude with the only limitation of the maximum range distance not to be exceeded.

As can be seen, in this manoeuvre the helicopter is exposed to detection by the enemy radar only during the launching phase of the missile.

In all modes of operation, the missile altitude is automatically controlled by a built-in altimeter. This enables precise control of altitude down to very low values (2 m or less). The missile flight height can be preset prior to launching, or changed during flight – choice depending upon the operational requirements, sea-state, etc. – either in accordance with a given programme or by means of a command signal transmitted to the missile, via the command link.

The missiles may be controlled in azimuth with two difnerent modes of operation: the radar mode, automatically in "all weather" conditions and the optical mode, a standby or "fair weather" system using an optical sight.

DEVELOPMENT:

In 1967 the Italian Navy began the preliminary studies required for strengthening the offensive capabilities of ground-based or ship-based helicopters by arming them with anti-ship missiles as a complement to the use of helicopters in antisubmarine warfare. Obvious requirements were those of ensuring the helicopter a high kill potential at stand-off ranges in its new surface role, as well as safe mission profiles. The solution adopted was the Sea Killer family of missiles.

The Italian Navy promoted a development programme known as the Marte project, with the firms SISTEL, as prime contractor, Agusta and SMA with the purpose of proposing a weapon system for installation on board helicopters of the Sea Killer missiles, which meanwhile had reached operational status in their ship-to-ship version. SISTEL was chosen because it had originated the Missiles, Agusta as the manufacturer of the helicopters while SMA specialises in radars.

ASM-1 AIR-TO-SURFACE MISSILE

DESCRIPTION:

Under the designation ASM-1 the first Japanese tactical air-to-surface anti-ship missile is being developed for use with the Mitsubishi FS-T2 close-support aircraft. No official details have been obtained but provisional characteristics are range approximately 45 km, speed about Mach 1, and it has been reported that a 140 kg warhead will be carried. It has been officially stated that the ASM-1 will also be capable of ship or ground launching by the addition of a rocket booster motor. An inertial system will be used for mid-course guidance and an active radar seeker for terminal homing.

STATUS:

In November 1973 Mitsubishi Heavy Industries Ltd was selected as prime contractor for the development of the ASM-1.

MANUFACTURER:

Mitsubishi Heavy Industries Ltd., 5-1 Marunouchi 2-chome, Chijoda-ku, Tokyo 100, Japan.

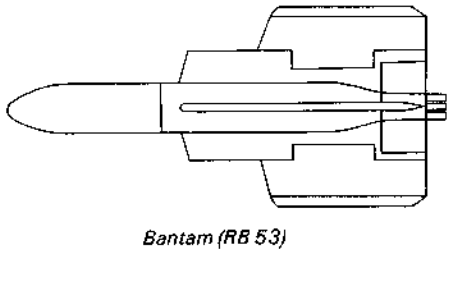
1652.311
BANTAM (RB 53) AIR-TO-SURFACE ANTI-TANK MISSILE

DESCRIPTION:

This is a helicopter version of the infantry anti-tank weapon system using the wire-guided Bantam missile. The Bantam has also been fired successfully from light aircraft like the Bulldog and Saab-MFI 17. The standard infantry control unit has been used with excellent scoring results. The missile itself is described more fully in Entry No. **2363.111.** Principal features are length 850 mm, body diameter 110 mm, span 400 mm, weight 7.5 kg. A two-stage solid-propellant motor is employed and a 1.9 kg hollow charge AP warhead is carried.



Bantam (RB 53)

STATUS:
The land version of Bantam has been adopted as standard equipment by the Swedish and Swiss Armies.
MANUFACTURER:
AB Bofors, S 690 20 Bofors, Sweden.

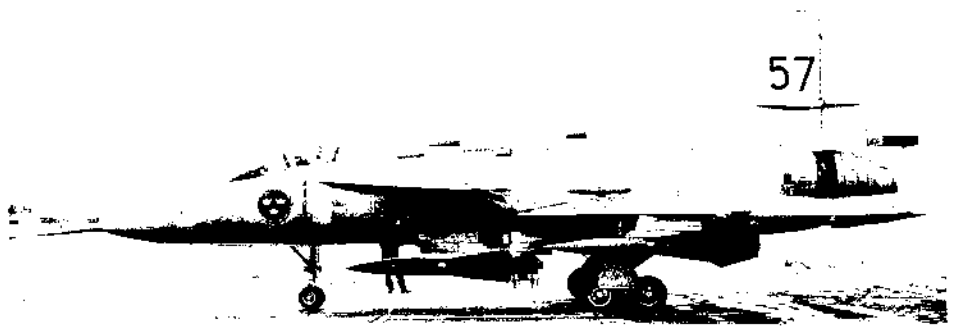
Launch of Bantam from Saab-MFI 17

1190.311
Rb 05A AIR-TO-SURFACE MISSILE
DESCRIPTION:
The Rb 05A is a radio command guided manually controlled tactical air-to-surface missile. It is for use against both sea and land targets but may also be used in certain air-to-air roles. Principal characteristics are: wing span 80 cm, diameter 30 cm, length 360 cm, and total weight about 305 kg.

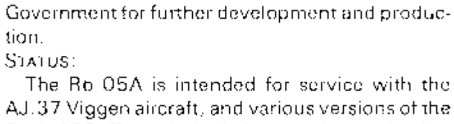


Saab Rb 05A air-to-surface missiles carried by AJ37 Viggen aircraft

The airframe of the Rb 05A is made of conventional aircraft materials and consists of a pointed cylindrical body with long-chord cruciform wings and aft-mounted cruciform control surfaces. A liquid rocket motor is centrally located and the motor casing forms part of the outer skin and load-carrying structure of the missile. The armament system is located in the nose and most of the control equipment at the rear of the missile. The VR 35 rocket motor is fitted with a tail-pipe which passes through the rear of the body. A pre-packaged liquid-propellant motor, supplied by Volvo Flygmotor AB, is used. The propellant tanks are placed around the centre of gravity to avoid CG-shift. Electrical power is supplied by a thermal battery, the battery remains unactivated until the time of firing the missile. Before launching some necessary electrical preheating of the missile is supplied from the aircraft. The hot gas for the control surface actuators is provided from a solid propellant gas generator. An effective proximity fused armament system is used, developed by the Swedish Research Institute of National Defence, and is manufactured under sub-contract by Förenade Fabriksverken.

The auxiliary airborne missile system equipment comprises a control stick, coding unit, transmitter and antenna. The control stick is designed to give good support to the hand even under severe conditions. In the coding unit conditioning of the control stick signals takes place prior to coding. The coded signal is fed to the microwave transmitter which transmits control signals in front of the aircraft by means of the antenna.

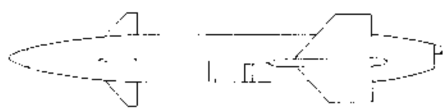
After launching the missile is guided manually by the pilot who visually lines up the missile track ing flares and the target. The control signals, indicated by the pilot through the special control stick, are transmitted over the radio link with the transmitter in the aircraft and the receiver in the missile aft section. The guidance transfer function, from control stick force to the missile's transverse acceleration, is specially designed to provide a high degree of guiding accuracy for both small and large off-set angles. The command link is difficult to jam because both coded signals and a very high transmitter output are used. Guidance signals received by the missile are converted by an autopilot to control surface deflections through the medium of four hot gas actuators. The autopilot initially guides the missile into the pilot's field of view.



RB 05A

DEVELOPMENT:
Developed by Saab-Scania on behalf of the Swedish Air Force, the system entered advanced testing in 1968/9. In June 1969, Saab was awarded a large contract by the Swedish Government for further development and production.
STATUS:
The Rb 05A is intended for service with the AJ.37 Viggen aircraft, and various versions of the Saab 105. The missile is in quantity production and has entered operational service at certain Swedish Air Force wings.
MANUFACTURERS:
Saab Scania Linköping, Sweden.

1189.321
ROBOT Rb 04 AIR-TO-SURFACE MISSILE
DESCRIPTION:
Air-to-surface missile developed principally for anti-shipping strikes. The version in current Royal Swedish Air Force service is the Rb 04D, but in mid-1968 it was revealed that an improved version under the designation Rb 04E was in development. Principal characteristics of the latter are as follows: length 445 cm, body diameter 50 cm, wing span 2 m and total weight about 600 kg. These figures are the same as for the earlier models, but the Rb 04E is stated to be technically very advanced. After launch, the missile acts in-



RB 04

dependently of the launch aircraft and is automatically guided to a low level altitude where target search and acquisition are performed at a high sub-sonic speed.

Guidance in the approach phase of an anti-shipping attack with the Rb 04E is probably by means of a high quality auto-pilot (perhaps based on an Aga platform) or a fixed course towards the target area. When within range of the missile's homing head, it will either use passive radar homing if the target is radiating, or active radar homing if the target is 'silent'.

DEVELOPMENT:

The Robot Rb 04 series of missiles was initiated by and developed by the Missile Bureau of the Swedish Air Force Board (now the Defence Material Administration – Missiles Directorate). This organisation was responsible for the development of the 04C and 04D versions, but subsequent R & D has been performed by Saab.

STATUS:

The Rb 04 was first introduced to the Swedish Air Force in 1959/60, and the C and D versions are standard weapon options for the A32A Lansen attack aircraft, which is capable of carrying two of these missiles.

Production of the Rb 04C ceased in 1964, and the Rb 04D entered operational service in 1971.

The Rb 04E is intended for use with the AJ37 Viggen all-weather attack aircraft, which can carry three missiles. The missile is in quantity production, this having started in 1973 following the award of a contract in 1969.

HAWKSWING HELICOPTER ANTI-TANK MISSILE

DESCRIPTION:

Hawkswing is one name given to a proposed helicopter installation of the BAC Swingfire (Entry No **2450.111**) anti-tank missile. An alternative name is Airstrike Swingfire. At the 1972 Farnborough Air Show a typical installation on a Lynx helicopter was shown in model form. A total of six rounds, three on each side, are carried ready for firing from their containers, and a further six to permit re-loading without having to return to base can be carried inside the helicopter. A more detailed description of the Swingfire missile and its operation will be found in the anti-tank missile section of this edition.

Hawkswing launch from Scout helicopter during early development trials

1530.321
SEA SKUA CL 834 HELICOPTER AIR-TO-SURFACE MISSILE

DESCRIPTION:

The CL 834 Sea Skua is a new helicopter-launched anti-ship missile system, initially under development for RN Lynx helicopters but expected to be more widely deployed in the future. The operational role of the weapon is to provide long-range self-defence for frigates against missile-carrying fast patrol boats, hydrofoils and hovercraft having a capability against frigates and larger vessels. It has been stated that the range of the missile itself will be great enough to provide the launching helicopter with a useful degree of 'stand-off' protection from return fire put up by the selected target. This, and the ability of the helicopter to operate at appreciable distances from its parent vessel, are intended to provide protection extending beyond the range of most surface-to-surface anti-ship missiles.

So far, the CL 834 has only been shown in model form, and no dimensions have been given officially. However, the model photograph indicates the missile configuration, and provisional dimensions are 2.83 m long, maximum body diameter 20 cm, span 60 cm, and weight approximately 210 kg. A high explosive warhead weighing about 20 kg is probable. A solid-propellant motor is used, and guidance is by semi-active radar homing, the target being illuminated by the Ferranti Seaspray radar in the Lynx helicopter. After launch, the CL 834 will reduce height to a few metres above wave level for the cruise phase of an attack. A pre-programmed or radio command instruction will bring the missile to target acquisition height for the terminal homing phase. An aircraft-launched version is understood to have been studied.

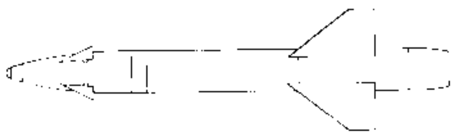
BULLDOG (AGM-83A) AIR-TO-SURFACE TACTICAL MISSILE

DESCRIPTION:

Bulldog is a laser-guided missile developed for close air-support for the US Marine Corps and designed to make maximum use of existing hardware and technology. It was officially stated in March 1974 that further development and procurement had been suspended, but this entry has been retained both as illustrative of the state-of-the-art and because later re-instatement is a possibility. It uses the Bullpup airframe (Entry No **1280.311**) and a new design guidance control unit (Guidance Control Group AN/DSM-126) which embodies a high proportion of the Sidewinder missile (Entry No. **1103.331**) technology. Since Bulldog uses existing components from other systems wherever possible, a reasonably inexpensive missile has resulted. It has also been designed to be compatible with a variety of existing laser target designators, and can be used on



Bulldog (AGM-83A)

A-4, A-6 and A-7 aircraft.

The main characteristics of the missile are length 298 cm, diameter 30.5 cm, and weight 272 kg. Propulsion is by either an LR-58RM liquid-propellant motor or Mk 8 Mod 2 solid motor, and a Mk 19 Mod 0 warhead is carried.

OPERATION:

Unlike laser guided bombs, which require normal ballistic bomb delivery techniques, Bulldog has a large delivery envelope and can be fired at long range and low altitudes. The system performance and unit cost make it appropriate for the destruction of small ships, bridges, tanks, and similar stationary and mobile targets. A Forward Air Controller, either on the ground or airborne, is responsible for target selection and for transmitting radio instructions to the attack aircraft to bring it to the target area. The FAC then operates the laser designator and illuminates the selected target. When the pilot activates the seeker in the nose of the Bulldog missile, it scans until it acquires the laser designated target. At that point, a light on the control panel and an audio signal indicate to the pilot that the target has been acquired. He aims the missile by means of pointers on a Target Position Indicator instrument, and then initiates the launch. From that point Bulldog is directed to the target automatically by the laser-seeking homing head. The missile itself leaves no vapour trail, thus enhancing the surprise element.

DEVELOPMENT:

The Bulldog weapon system AGM-83A, was developed by the US Naval Weapons Centre, China Lake, California, in response to a US Marine Corps requirement for a close air support weapon. The new guidance control group was developed jointly by the Naval Weapons Centre and Texas Instruments, and a contract was awarded to the latter in late 1972 for pilot production of that component. During 1972 a variety of land and sea target situations were evaluated in 27 test launches, and a high success ratio was achieved.

US Marines loading Bulldog missile onto US Navy aircraft for trial at China Lake (US Navy Official Photograph)

STATUS:

Bulldog was in pilot production at the beginning of 1973. Despite the apparent success of the Bulldog programme, it was announced by the Director of Defence Research and Engineering in March 1974 that no funds were being requested in the Fiscal Year 1975 Defence Budget for continuation or procurement of Bulldog. He said, "Strong action has been taken to eliminate duplication in laser-guided missile developments. Our goal has been a common laser guided missile for fixed-wing aircraft of the Air Force, Navy and Marine Corps and a common seeker for all the Services. No funds are being requested to procure the Navy Bulldog because we are convinced that laser Maverick can meet the needs of the Air Force, Navy and Marine Corps. I am directing the Air Force to hold a competition to select a common multi-Service seeker".

1280.311
BULLPUP (AGM-12) AIR-TO-SURFACE TACTICAL MISSILE

DESCRIPTION:

The Bullpup AGM-12 series of missiles embraces a range of air launched missiles for attacking tactical surface targets on land or sea. Guidance is by radio command link from the launching aircraft, with optical tracking to target, aided by flares attached to the missile.

Bullpup model designations run from AGM-12A to AGM-12E, and within this group quite considerable variations of payload (and hence dimensions) exist. There are also Bullpup trainer versions carrying ATM-12 designations. These are essentially inert rounds for pilot training.

Early versions of Bullpup employed a US Navy-developed solid fuel rocket motor, but all current models use pre packed liquid fuel motors (LR62/LR58, Thiokol Reaction Motors) which permit long storage time and rapid missile preparation.

The several variants of Bullpup carry either 250 lb (113.4 kg) or 1,000 lb (453.6 kg) conventional high explosive warheads, or a nuclear warhead. Maximum speed is variously quoted by the manufacturers and the USAF as: over Mach 2, Mach 1.8, and 1,400 mph. Range quotations also vary but are approximately 11 km and 17 km for the small and large versions, respectively.

Principal characteristics are as follows: Bullpup A (AGM-12B):

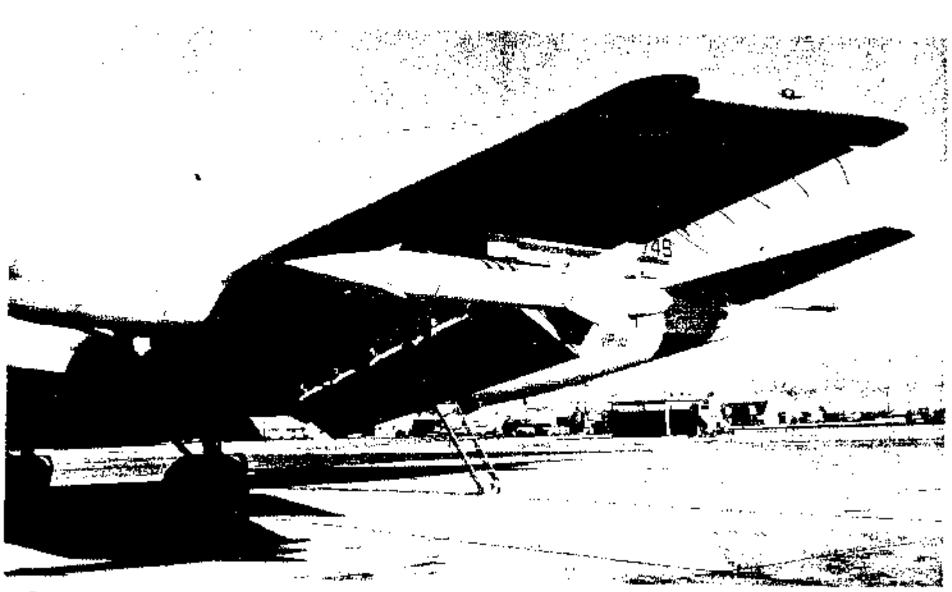
Length 3.2 m, diameter 30.5 cm, wing span 95.25 cm, launch weight 258 kg.

Bullpup B (AGM-12C)

Length 4.07 m, diameter 43.9 cm, wing span 117.76 cm, launch weight 812 kg.

OPERATION:

Bullpup is launched on the appropriate line of sight from the aircraft to the target, and is then visually tracked by the pilot who uses a radio command link to direct the missile to impact. Two high-intensity flares in the aft end of the missile aid tracking.



Bullpup air-to-surface missile on wing of US Navy P-3B Orion aircraft (US Navy Official Photograph)

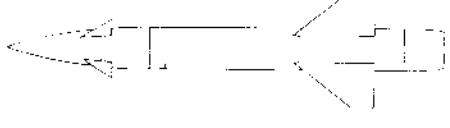
DEVELOPMENT:

Development originated in 1954, and the Martin Company and Maxson Electronics Corporation embarked on a long running programme involving production and continuous further development of the Bullpup system.

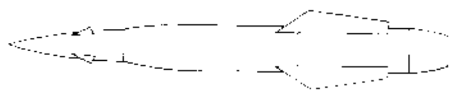
In March 1970 Texas Instruments was awarded a \$1.9 million contract by the US Navy to develop a laser guidance system for the Bulldog (1655.311, above) version of Bullpup.

STATUS:

Bullpup became operational in 1959 and is now in use by the US Navy, Air Force and Marine



Bullpup A (AGM-12B)



Bullpup B (AGM-12C)

Corps, and numerous NATO services.

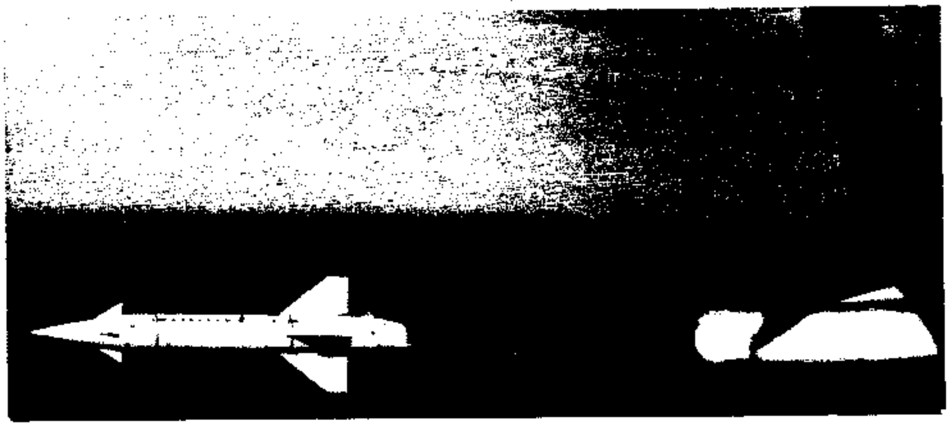
Foreign users include the Royal Navy which has selected the AGM-12B as standard strike armament for the Sea Vixen and Buccaneer aircraft. This version of Bullpup is manufactured under licence in Europe for the armed forces of Denmark, Norway, Turkey and the UK by a consortium headed by Kongsberg Vaapenfabrikk. American production has ceased.

MANUFACTURERS:

Martin Marietta Corporation, Orlando, Florida, USA.

Maxson Electronics Corporation, Sunrise Highway, Great River, Long Island, New York 11739, USA.

A/S Kongsberg Vaapenfabrikk, Norway – prime contractor for European consortium.



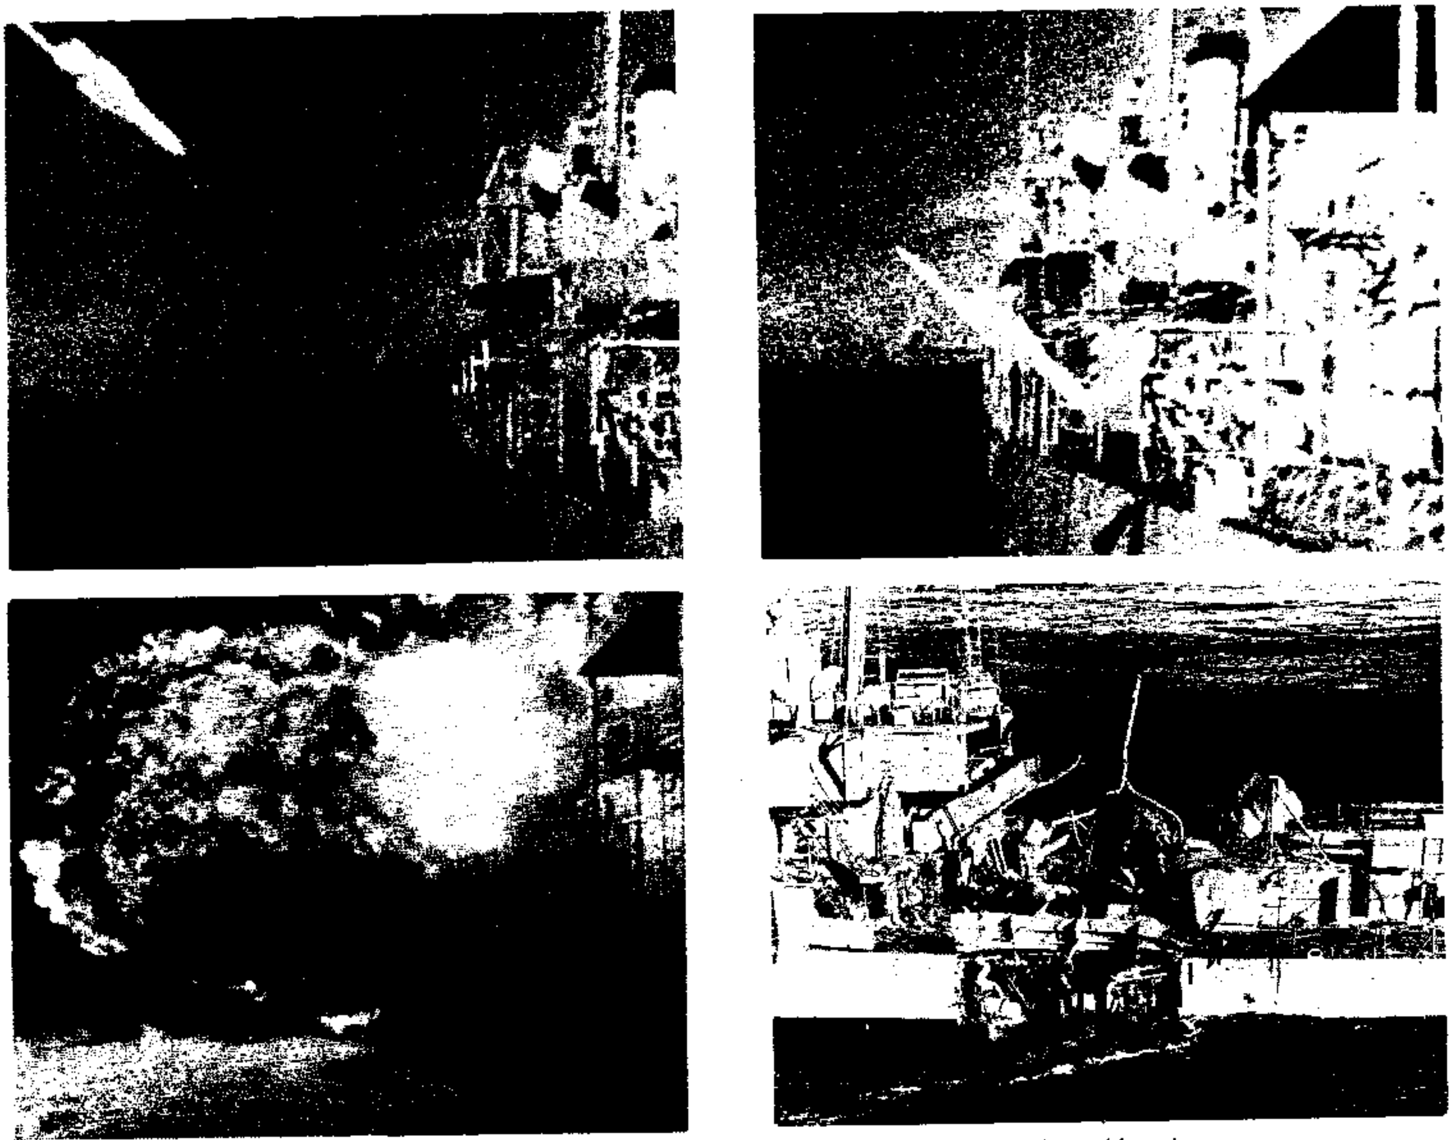
Bullpup firing from US Navy Orion maritime aircraft (US Navy Official Photograph)

1081.311
CONDOR (AGM-53A) AIR-TO-SURFACE TACTICAL MISSILE

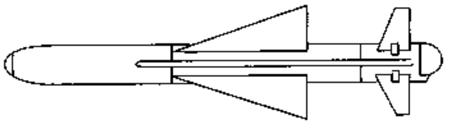
DESCRIPTION:

Condor is a medium-range, supersonic cruise missile using a TV remote guidance and control system to provide the US Navy a standoff capability against heavily defended, high value, surface targets. Principal characteristics are: length 1.67 m, diameter 43 cm, wing span 135 cm, launch weight 966 kg, warhead 286 kg. The range has been estimated at from 60 to 80 km. In addition to the missile itself, the Condor weapon system consists of a control system pod and the aircraft installation. The former contains the data link system, with fore and aft aerials; a special-purpose digital computer which performs automatic mid-course guidance as well as built-in test and pre-launch functions; a mission recorder; and space provision for an inertial navigation unit. The cockpit installation comprises a TV display, missile controller, and system controls. In tests in late 1971, in which a Condor was launched from an A-6A aircraft against a moored destroyer escort target vessel, a hit was scored at a range of 56 km.

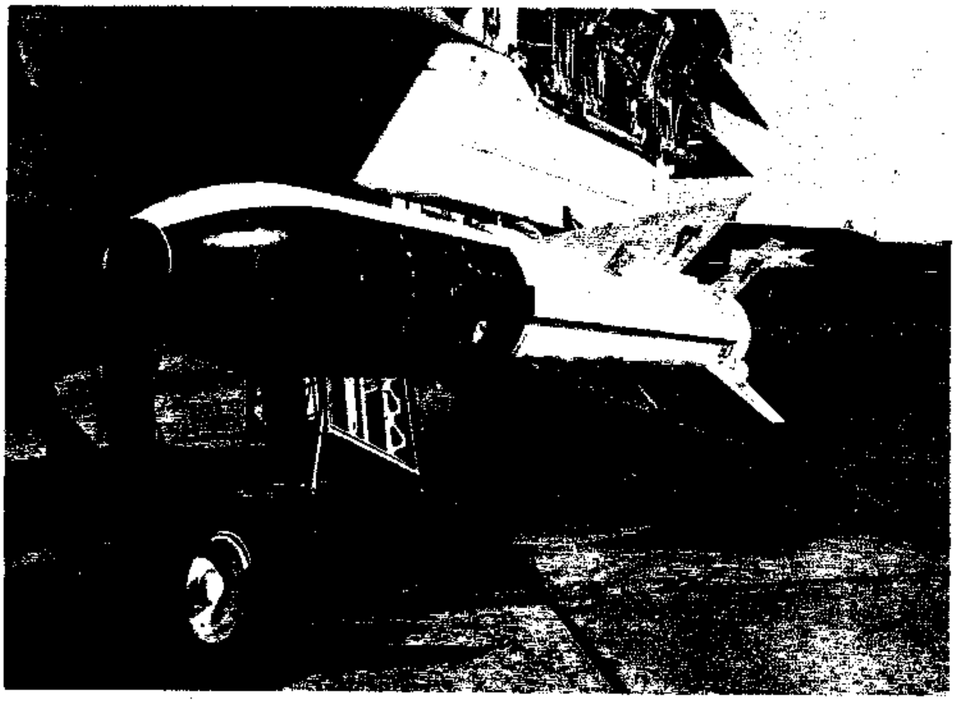
A conventional high explosive warhead is carried but it is believed that some consideration has been given to an alternative nuclear warhead. Since its inception in the mid-1960s, the Condor system has been the subject of a number of studies relating to alternative guidance and propulsion methods and it seems probably that this weapon will ultimately be procured in more than one version. In addition to the possibility of an alternative nuclear warhead, mentioned above, other possibilities and changes which have been pursued are an extra, turbo-jet engine for longer range, a dual-mode (EO and radar) homing head, and a different data link.



This remarkable sequence of pictures, three of which are single frames from a filmed record from the target ship, show a Condor missile homing onto its target by electro-optical guidance and the ensuing explosion. The final picture shows the damage sustained. (US Navy Official photographs)



Condor (AGM-53A)



Condor (AGM-53A) air-to-surface missile

The original data link arrangement planned for Condor is a sophisticated equipment, designed to provide secure operation (eg. within a potentially hostile electromagnetic environment, from ECM etc) and simultaneous Condor launches from several carrier aircraft. The use of a 'non-secure' data link offers the chance of worthwhile cost reductions while remaining perfectly adequate for many operational applications, and work is in progress to adapt the Walleye II (**1129.311**) data link to Condor.

A complete new nose section for the missile is envisaged for the so-called 'dual-mode' Condor guidance system, and it is expected that this will be interchangeable with the standard TV homing head and guidance package. The standard Condor has daylight and "non-interfering" cloud cover capability only, which is taken to mean that cloud penetration under automatic flight control is possible, the Condor must emerge from cloud under conditions which will permit TV guidance to the target. Day and night all-weather operation is the eventual goal. The all-weather mid-course capability has been demonstrated, and Condors have been flown through clouds in the mid-course areas on the automatic mode to the terminal area using the data link and mid-course navigation.

For the full all-weather mode the TV system is supplemented by an active radar in the new-type nose guidance section of the missile mentioned above. This contains the EO (TV) section, chin mount and radar system, and it will add slightly to overall missile length.

In operation the following sequence takes place. After the launch phase there is a search mode, followed by a map-while-track (MWT) mode by which a radar terrain map obtained by the Condor's radar is returned by data to the launch aircraft for display. The television picture is returned also for simultaneous presentation, thereby permitting navigation and up-dating operations. During the terminal phase, the missile will be transmitting only video data. The radar will be operating in a monopulse tracking mode. Since there will be no radar picture generated, the TV data can be used to monitor the target approach up to the moment of impact. The all-weather Condor will be deployed on TRAM (Target Recognition and Attack Multi-sensor) fitted A-6E aircraft. By means of a modification kit costing about $50,000, Condor can be integrated with TRAM so that the latter system's TV and radar displays can be used for Condor guidance in addition to their original functions of presenting radar, TV, and infra-red data derived from sensors fitted to the A-6E aircraft and forming part of the overall TRAM installation.

DEVELOPMENT:

The requirement against which Condor is being developed originated in 1962. Requests for Proposals were issued in 1964, and Rockwell International was selected as Research Centre, in May 1972.

STATUS:

Condor has completed engineering development and is entering pilot production.

The first Condor powered launch was made on March 31 1970.

On February 4 1971, a Condor launched from an A-6 aircraft scored a direct hit against the former Navy destroyer escort, USS *Vammen*, off the California coast. The Navy said the test was the first live warhead test and third consecutive successful test flight and demonstrated the missile's ability to strike surface ships from beyond the range of their anti-aircraft defences.

In March 1974 the US Secretary of Defence reported that development of the basic missile was essentially complete, and that pilot production missiles are being procured with Fiscal Years 1973-74 funds for operational test and evaluations of Condor. Engineering development and flight testing of the dual mode radar and electro-optical seeker version of Condor will be carried out in Fiscal Years 1975-76. The Fiscal Year 1975 Budget includes $30.2 million for this programme; $10.2 million for continued development and $20 million for procurement of 35 pilot line missiles, the minimum possible to keep the line running pending a decision on full-scale production in early 1975. With this latest production increment, a total of 85 Condors have been procured over the past three years.

MANUFACTURERS:

Rockwell Autonetics Division, Anaheim, California, USA – digital computers.

Curtis-Wright Corporation – flight control system.

Hughes Aircraft Company – data link guidance.

Rockwell, Rocketdyne Division – solid rocket motor.

1129.311
WALLEYE (AGM-62A) AIR-TO-SURFACE MISSILE

DESCRIPTION:

The Walleye weapons family consists of three models of unpowered, guided bombs, designated Walleye Mks I and II and Extended Range, Data Link Walleye. Walleye I has the following main characteristics: length 344 cm, diameter 32.5 cm, wing span 116 cm, weight 499 kg. Conventional, Mark I Mod 0 850 lb (385 kg) high explosive warhead.

Walleye II, which has the USN designation Guided Weapon Mk 5, Mod 4, is a much larger missile than the AGM-62A Walleye. Length of Walleye II is 404 cm, body diameter 45.7 cm and weight 1,061 kg. A warhead in the 2,000 lb (907 kg) class is carried, and the weapon was designed for the destruction of large semi-hard targets such as bridges, air base facilities and ships.

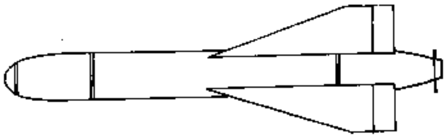
The latest version is Extended Range, Data Link Walleye II (ER/DL WE II) which has the USN designation Mk 13 Mod 0. This is essentially a Walleye II fitted with larger wings to extend the glide range and data equipment. The data link was originally intended for single aircraft use of Walleye to enable earlier release (by virtue of the extended glide range) and remote acquisition and lock-on of the Walleye's EO homing system while the launch aircraft had already begun its escape manoeuvre. Experience in SE Asia led to a change in philosophy, by which the data link terminal (and control functions) were transferred to a companion aircraft which followed the Walleye carrier aircraft.

OPERATION:

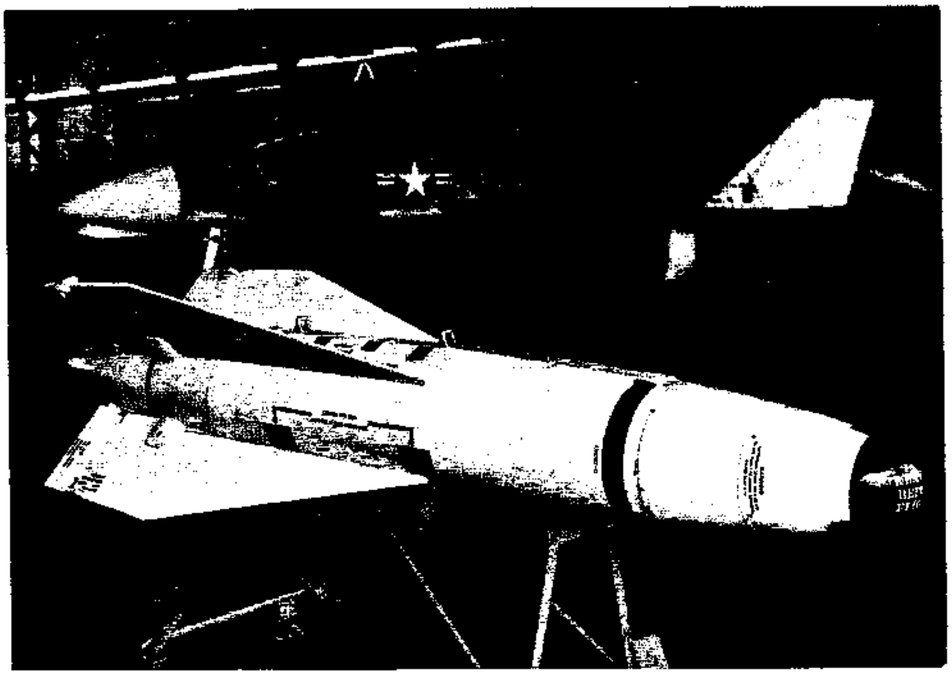
A gyro-stabilised TV camera in the nose of the weapon is aligned with the target prior to launch by the pilot. He is aided in this by a CRT monitor screen, and for target acquisition either the Westinghouse AN/APQ-100 or APQ-109A fire control radar may be used. Modified displays have been produced by Texas Instruments for use in the

A-7 Corsair II aircraft carrying Walleye II during flight tests (US Navy Official Photograph)

Destruction of the Ninh Binh bridge in North Vietnam as recorded by the TV camera in the nose of the Walleye bomb (US Navy official Photographs)



Walleye II (AGM-62)



Walleye II air-to-surface glide weapon carrying 2,000 lb class warhead, awaiting loading onto aircraft for flight tests (US Navy Official photograph)

latter system.

When the target has been identified by the pilot, the missile TV camera is locked on and after release the missile guidance and control system uses signals from the TV head to produce control surface movements to direct the bomb to the target. The aircraft is thus free to quit the area immediately after releasing the weapon.

A Prestolite ram air turbine is used to drive a solid-state alternator which generates electrical power for the TV and control systems.

Development:

Initial development was performed by the US Naval Ordnance Test Station, China Lake, in 1963. The following year the Naval Avionics Facility entered the programme and in July 1964 requests for proposals were issued. Contract definition phase followed some months later in January 1965, when Hughes, North American and Martin-Orlando each received contracts. The last of these three concerns was nominated prime contractor in January 1966, and a $12.1 million contract was awarded which covered initial production. Later the same year the contract was increased by a further $11.1 million, and a $34.5 million contract followed in early 1967 covering production for the USN and USAF.

In November 1967 Hughes was designated as a second source prime contractor for the AGM-62A, and an award of $15.9-million was made to the company.

Moves to develop an improved version of Walleye took place in 1968 when a number of contracts were placed for the study and development of new components. Various designations attributed to this version are Fat Albert, Walleye II and Large Scale Walleye.

The US Naval Weapons Centre, China Lake, California, developed and tested Walleye II with assistance from Hughes Aircraft Company, Canoga Park. In March 1971 a pilot production contract for the warhead, wings and fins was awarded to Martin Mariette, Orlando, Florida. The Naval Avionics Facility, Indianapolis, modified Walleye I guidance and control sections for the Walleye II pilot production.

Status:

Walleye is widely deployed with the USN and USAF, and Walleye II is in production for the USN. Aircraft types that have, or which are projected to carry this weapon include F-4, A-4E/F and A-7A/B/C/E.

Manufacturers:

Martin Marietta Corporation, Orlando Division, PO Box 5837, Orlando, Florida 32805, USA.

Hughes Aircraft Company, Missile Division, Canoga Park, California, USA.

1102.311
SHRIKE (AGM-45A) AIR-TO-SURFACE MISSILE

Description:

Anti-radiation air-to-surface missile for the destruction of ground defensive radar installations. Official details include: length 304.8 cm, diameter 20 cm, wing span 91.4 cm, weight 177 kg, solid-propellant rocket motor. Estimated speed and range are: Mach 2 and 12 to 16 km.

Operation:

Initial warning of illumination of Shrike-carrying aircraft by ground defence radars is probably obtained from ECM receivers installed in the aircraft. When within appropriate range, the Shrike sensor heads are switched on and the missiles fired when target acquisition has been achieved. After release, the missile radar receiver continously senses the direction of arrival of radar radiation from the target and generates command signals for the missile guidance system to home it on to the radar.

Shrike guidance heads have been developed

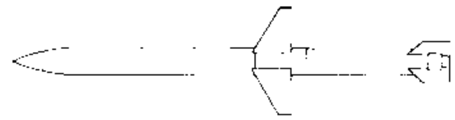
Shrike AGM-45A air-to-surface anti-radar missile prepared for flight testing at China Lake, US Naval Weapons Centre (US Navy Official Photograph) that provide for effectiveness against enemy early warning, ground control intercept and SAM guidance radars, each of which covers a different frequency range. The frequency range of a particular Shrike version is denoted by a suffix number to the AGM-45A designation, and there are at least 13 of these. The relationship between these numbers and the radar frequency bands is classified but a few other details are available. The -5 model was cancelled before production started. The -1, -1A and -2 models produced between 1963 and 1966 are thought to have covered the X and C-bands. The -3, -3A, and -3B were produced from 1963 to 1969 and may have an anti-ship radar role. The -4 was produced between 1965 and 1968, and the -6 has been used by USAF and USN from 1965 to 1970. The -7 is thought to cover one or more of the lower frequency bands. The -8 programme ran from 1967 to 1970/1 when it was cancelled in favour of HARM development. The -9 is for USAF and is in development, while the -10 is still under consideration by the USAF. Based upon the specific radar to be attacked, the operational commander selects the most appropriate weapon option. The USAF uses Shrike on modified F-105 and F-4 aircraft, termed WILD WEASEL aircraft, with special radar homing and warning equipment. The USN employs the missile on A-4, A-6 and A-7 aircraft.

DEVELOPMENT:

System Manager for the Shrike programme was the US Naval Weapons Centre, and development started in 1962. Production started in 1963, with operational deployment in 1964. Initial experience in Viet Nam was disappointing and a series of improvement programmes was instituted and these are now reported to have proved successful.

STATUS:

Production is continuing for use on both USN and USAF aircraft. The USAF is known to have procured 1,200 missiles in Fiscal Year 1969 and 300 in Fiscal Year 1970, both services were



Shrike (AGM-45A)

authorised funds in Fiscal Year 1971 for the purchase of guidance heads designed for use against the more advanced models of surface-to-air missile (SAM) guidance radars. Two-source procurement has been applied throughout most of the Shrike programme. Shrike procurement in Fiscal Years 1973, 1974 and 1975 amounts to 1972, 1660 and 1200 missiles, respectively, the combined cost of these being $118.3 million.

MANUFACTURERS

Joint prime contractors: Texas Instruments and Sperry Rand/Univac.

1097.311
HORNET (ZAGM-64A) AIR-TO-SURFACE MISSILE

DESCRIPTION

The origins of the ZAGM-64A lie in a USAF programme for the development by Rockwell International of an air-to-surface bombardment missile, following a private venture proposal by Rockwell for a missile known as Anti-Tank Guided Aircraft Rocket-ATGAR. The award of a contract in 1963 was followed by air firings from an F-100F in November 1964. Test and evaluation continued and various guidance methods, including magnetic and at least two electro-optical systems, were tried.

The ZAGM-64A programme, as such, is stated to have ended in March 1968.

The Hornet was revived in 1970 as a test vehicle for a variety of guidance packages, mostly of electro-optical or laser types. A more powerful rocket motor and a cold-gas actuation system were subsequently incorporated, the former providing a booster-glide trajectory of more than four kilometres. A particularly successful series of test flights combining semi-active laser seekers with the Hornet missile were conducted in 1971 and 1972 by the US Army's Missile Command. These trials demonstrated terminal homing accuracies comparable with direct hit attacks on point targets. The laser Hornet programme is at present providing concept validation data to support the US Army Hellfire missile system. This work was combined with another programme initiated by a $14 million USAF contract awarded to Rockwell for the development of so-called 'smart' bombs (Entry No. **1579.331**). These are conventional bombs to which a guidance and control system had been added to yield greater accuracy by providing for modification of the trajectory after release. The combination of Hornet guidance elements with conventional bombs led to the HOBO concept. The term is sometimes translated as Homing Bomb System (HOBOS).

MANUFACTURER:

Rockwell International, Missile Systems Division, Columbus, Ohio, USA.

Hornet (ZAGM-64A)

1098.311
MAVERICK (AGM-65A) AIR-TO-SURFACE MISSILE

DESCRIPTION:

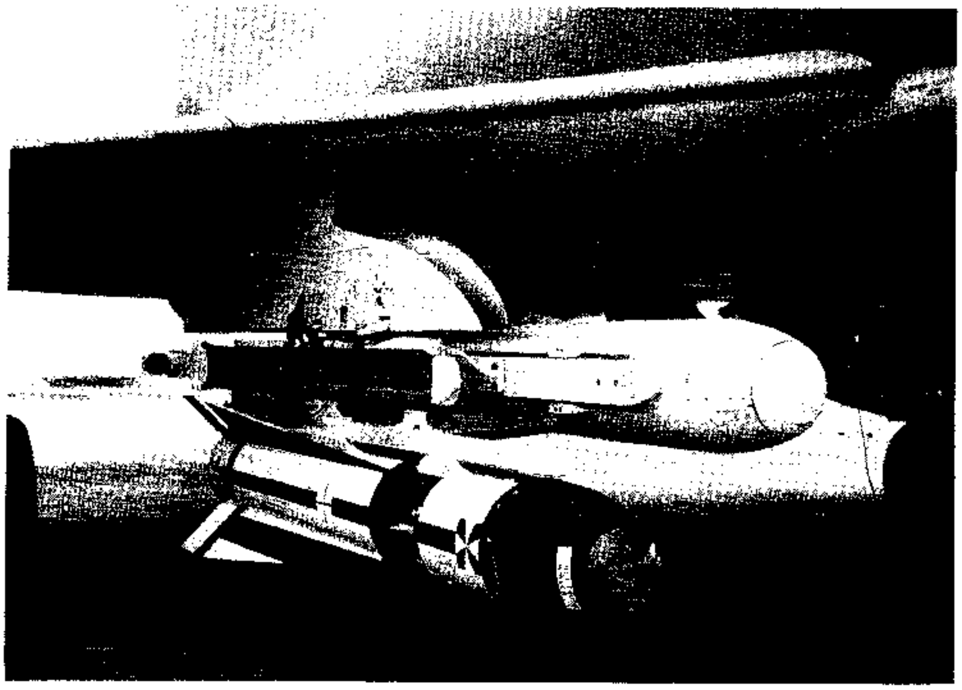
Maverick is a relatively small, television-guided tactical missile designed for use against small concentrated targets such as armoured vehicles, concrete field fortifications, revetments, gun positions, parked aircraft and communications vans. The missile, can be carried by F-4D and E and A-7D aircraft, is 246 cm long, 30 cm in diameter, has a 71 cm wingspan and weighs 209 kg. The warhead is a 59 kg high explosive conical-shaped charge, designed for high penetration. The weapon is powered by a Thiokol two-stage solid fuel rocket motor and will be mounted in clusters of three.

OPERATION

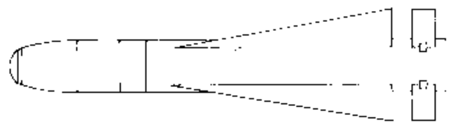
Maverick is guided by a miniature television homing system in the nose of the missile. On selecting a missile prior to engaging a target, gyro run-up is initiated and when this is completed (normally about three minutes) an indicator lamp is lit to tell the pilot he may uncage the gyro. This action releases a protective dome from the nose of the missile. The aircraft pilot picks up the target on a television monitor in the cockpit, locks the missile's electro-optical tracker onto the target (by either slewing the missile's nose-mounted TV camera, or changing the aircraft attitude) and launches the missile, which is automatically guided to the target by the television centroid tracker. The launch aircraft is free to take necessary evasive action once the missile is launched.

DEVELOPMENT:

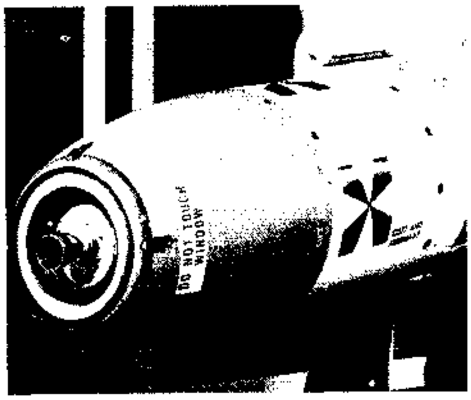
The Maverick development programme was approved by DoD in 1965 although related experimental work had been conducted earlier in the Hornet programme (which see). Requests for Proposals were issued in 1966, and Hughes was selected as prime contractor and awarded a $95 million fixed price incentive contract in June 1968. An alternative version of Maverick, using



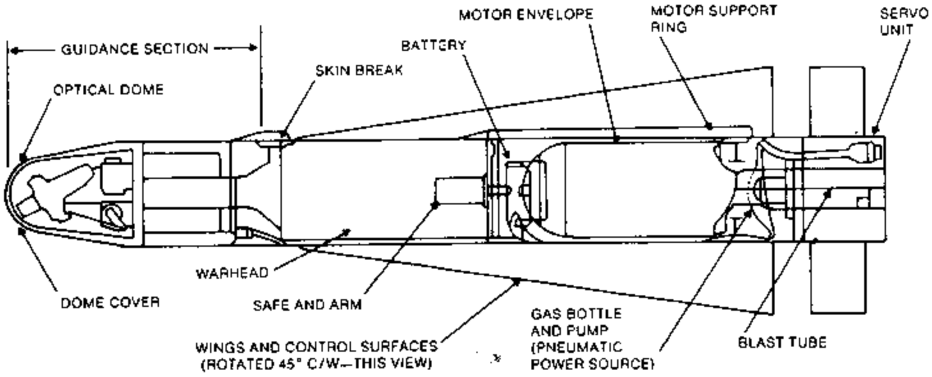
Maverick missile on triple launcher/adaptor



Maverick (AGM-65A)



Close up of Maverick optical guidance head



Internal arrangement of Maverick

laser-seeking guidance is under development in the Close Air Support Weapon System, described in Entry No. **1768.311**.

STATUS:

The initial production decision was to have been made in June 1970, but in March 1970 the USAF announced that funding constraints would force it to delay exercise of this option. The USAF requested $87 million to begin procurement in Fiscal Year 1972.

A production contract for 2,000 missiles valued at $69.9 million was awarded in September 1971, with first deliveries being made at the end of August 1972. In November of that year the USAF awarded a contract worth $47.7 million for a further 3,000 Maverick missiles. In Fiscal Year 1974 another batch of 3,000 was funded and the Fiscal Year 1975 procurement was doubled, to 6,000, to give a total of about 14,000 produced. The original total production envisaged was at least 17,000 missiles, and it seems possible that this number may be exceeded.

In addition to use by the US Forces, sales to Iran and Israel have been reported, the latter nation allegedly using Maverick to effect in the 1973 Middle East conflict.

MANUFACTURERS:

Hughes Aircraft Company, Culver City, California, USA.

1768.311
CLOSE AIR SUPPORT WEAPON SYSTEM (LASER MAVERICK)

DESCRIPTION:

The Close Air Support Weapon System (CASWS) will be a laser-guided Maverick to exploit the performance of that weapon and to derive maximum benefit from the broad production base which exists for Maverick. It is intended to provide a new day and night attack capability for countering armour and suppressing enemy air defences. Another, related objective is the ability to co-operate much more closely with the troops on the ground. An operational requirement of the system is that it should be possible for the launch aircraft to provide its own laser target designation facilities or for these to be provided by either a Forward Air Controller aircraft or by a ground laser marker. Provision for coding the laser illuminiation is required.

Modification to the Maverick missile (described in Entry No. **1098.311**) consists simply of substituting a laser-seeking homing head for the original TV homing head. This part of the project, selection of the laser seeker, relates to the so-called Tri-Service Seeker programme which has the objective of deciding upon a common laser seeker for use by all arms of the US Forces. It is also hoped that the USN, USAF and USMC will be provided with a common laser-guided missile for their fixed-wing aircraft.

DEVELOPMENT:

The programme started with a series of studies undertaken before 1970, and these were completed when initial industry studies confirmed the feasibility of meeting USAF requirements. In June 1971 there was a decision that Maverick could provide the appropriate platform for the project and advanced development was started in May 1972. Tests of various seekers, including examples from Texas Instruments and Rockwell (North American) were carried out later that year. RDT&E funding in Fiscal Years 1973 and 1974 was $4.4 million and $5.0 million, respectively. The Fiscal Year 1975 Budget sees a big increase for this programme, up to $20.0 million. No contractor had been named by May 1974.

1597.311
HOBO (EO) & LASER-GUIDED SMART BOMBS

DESCRIPTION:

There are two types of smart bombs currently in use by the USAF – the laser-guided bomb (Entries Nos. **1533.311** and **1534.311**) first introduced in Southeast Asia in May, 1968, and electro-optically (EO) or HOBO bombs which entered service in that theatre in February, 1969. The former type of munition is used in 500, 2,000 and 3,000 lb categories and the EO bomb is produced in 2,000 and 3,000 lb sizes.

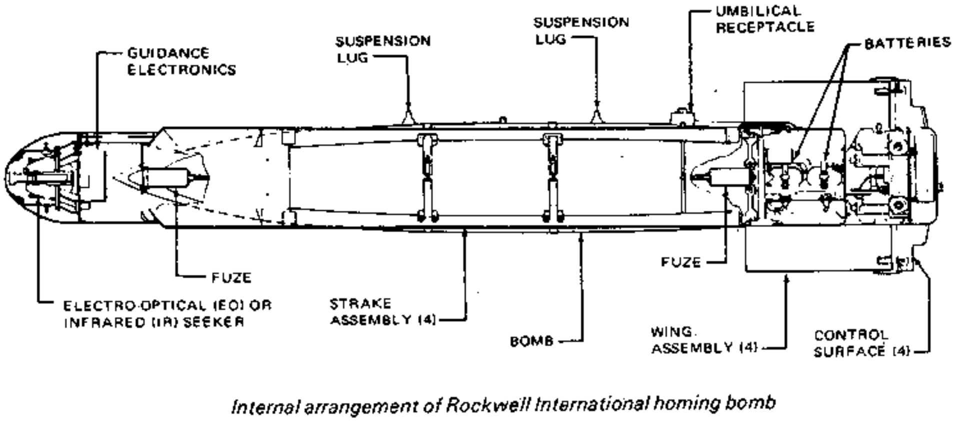
The laser-guided type consists of a conventional bomb to which are added stabiliser fins, a computerised directional package in place of the normal fuse, and a guidance module containing a laser seeker. The EO bomb has strakes running the length of the weapon and control surfaces at the rear, with a television guidance module at the front. A monitor in the aircraft is used by the crew for initial target acquisition, and after lock-on by the bomb's camera has been confirmed the weapon can be released, after which the guidance module steers the bomb to the target.

The laser-guided versions are reported to cost $3,100 each, and the EO versions $13,000 each. In both cases CEP errors are claimed to have been reduced to a few feet.

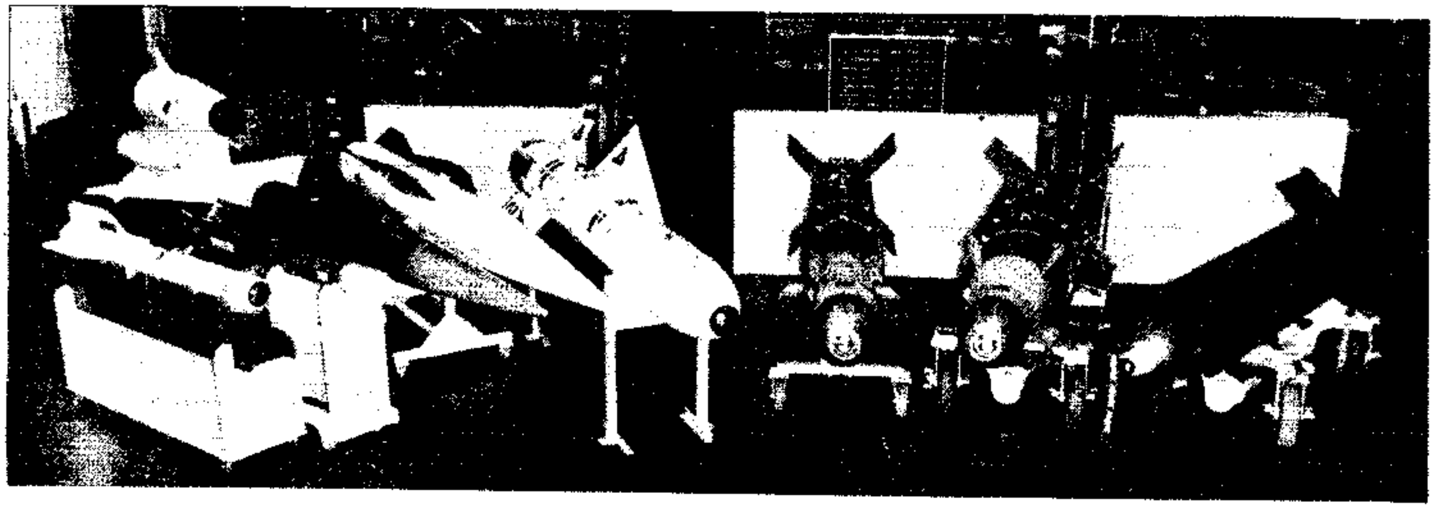
DEVELOPMENT:

In the latter half of 1972 the USAF, with industry, instituted studies of possible ways of further enhancing the smart bomb concept by the provision of blind attack facilities and extending the effective range to permit 'stand-off' operations. Because smart bombs EO or laser directed,

Laser-guided smart bombs



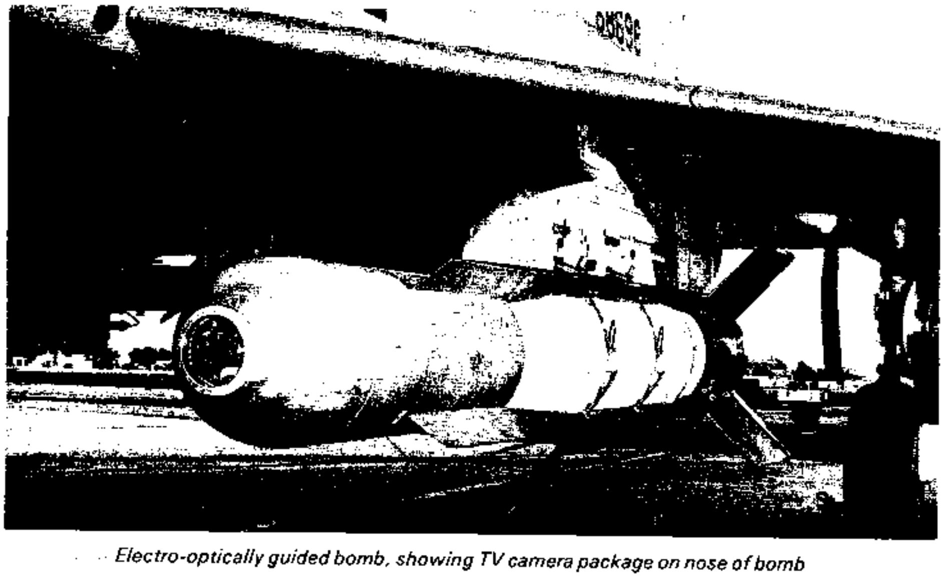
Internal arrangement of Rockwell International homing bomb



A selection of the latest US air-to-ground guided weapons, all developed by the Missile Systems Division of Rockwell International. Left to Right: *USAF Hornet anti-tank missile, US Army Terminal Homing flight, test vehicle, Redhead/Roadrunner target missile, Low-Altitude Short Range Missile (LASRM), Condor stand-off tactical missile, MK 84 EO smart bomb, M 118 EO bomb, and Mk. 84 infra-red guided bomb*

are capable of only modified-ballistic trajectories, effective stand-off ranges cannot be achieved under all conditions. The latest development overcomes this objection by providing the bomb with wings that are sprung into the flight position after the release from the parent aircraft. The bomb is thus given increased range by the ability to glide into the target area. The Celesco Industries modification kit includes, in addition to the wings, an autopilot to control the bomb until the terminal homing system takes over.

Bombs of this type have been designated Modular Guided Glide Bombs (MGGB) and Rockwell International has produced a number of these weapons based on the Mk 84 2,000 lb bomb. A variety of techniques for mid-course guidance are being studied and evaluated, the principal tactical objective of the system being the suppression of ground-based air defence installations. One method is for the missile operator in the parent aircraft to be equipped with a TV monitor which would display the video from the camera in the nose of the bomb, returned to the aircraft via data link. A link in the opposite direction would enable him to control the bomb's glide until target acquisition, after which the wings would be discarded and the terminal homing system would take over.



Electro-optically guided bomb, showing TV camera package on nose of bomb

A more sophisticated technique involves the provision of an on-board navigation system for the bomb, such as DME, Loran, or Omega, to enable it to navigate itself to a target area defined in co-ordinates determined by the release aircraft and/or co-operating aircraft. This method is appropriate to the engagement of radiating targets such as missile battery radars which might be located by TOA (Time-of-Arrival) Elint techniques.

Demonstration flights of the MGGB began in December 1972, and development is continuing, possibly at reduced speed since the disengagement from SE Asia by the USA.

In the UK, the Rockwell International E-O Seeker is under evaluation for the MoD by the Royal Aircraft Establishment and BAC as a possible air-to-surface weapon guidance system. Flight trials are taking place in a Hawker Siddeley Shackleton aircraft.

STATUS:

Modification kits have been produced by Rockwell International's Missile Systems Division for two standard US bombs, the 2,000 lb (900 kg) Mk 84 and the 3,000 lb (1,360 kg) M118E1. Kit designations are KMU-353A/B, KMU-390/B, and KMU-359/B, the first two being electro-optical and the last infra-red. Each kit consists of a guidance section for mounting on the nose of the bomb; a tail assembly with four stabilising vanes having control surfaces on their rear edges, and containing batteries; and a set of strakes and metal straps which serve to locate the guidance and control packages on the body of the bomb.

Rockwell International, Missile Systems Division, Columbus, Ohio, USA.

1534.311
PAVEWAY LASER GUIDED BOMBS

DESCRIPTION:

A family of bombs utilising a common laser guidance and control subassembly, with only the aerodynamic surfaces (control fins and aerofoil group) changed to match the particular size bomb. System allows standoff capability while providing precision weapon delivery against a wide spectrum of targets.

Present applications:

KMU-342/B	Conventional 750 lb M117 GP Bomb
KMU-351A/B	Conventional 2000 lb MK 84 GP Bomb (High and Low Speed Versions)
KMU-370B/B	Conventional 3000 lb M118 Demolition Bomb
KMU-388B/B	Conventional 500 lb MK82 GP Bomb (High and Low Speed Versions)
KMU-420/B	Conventional 500 lb MK20 MOD 2 (Rockeye) Cluster Munition
KMU-421/B	Conventional 2000 lb SUU-54/B (Pave Storm) Cluster Munition

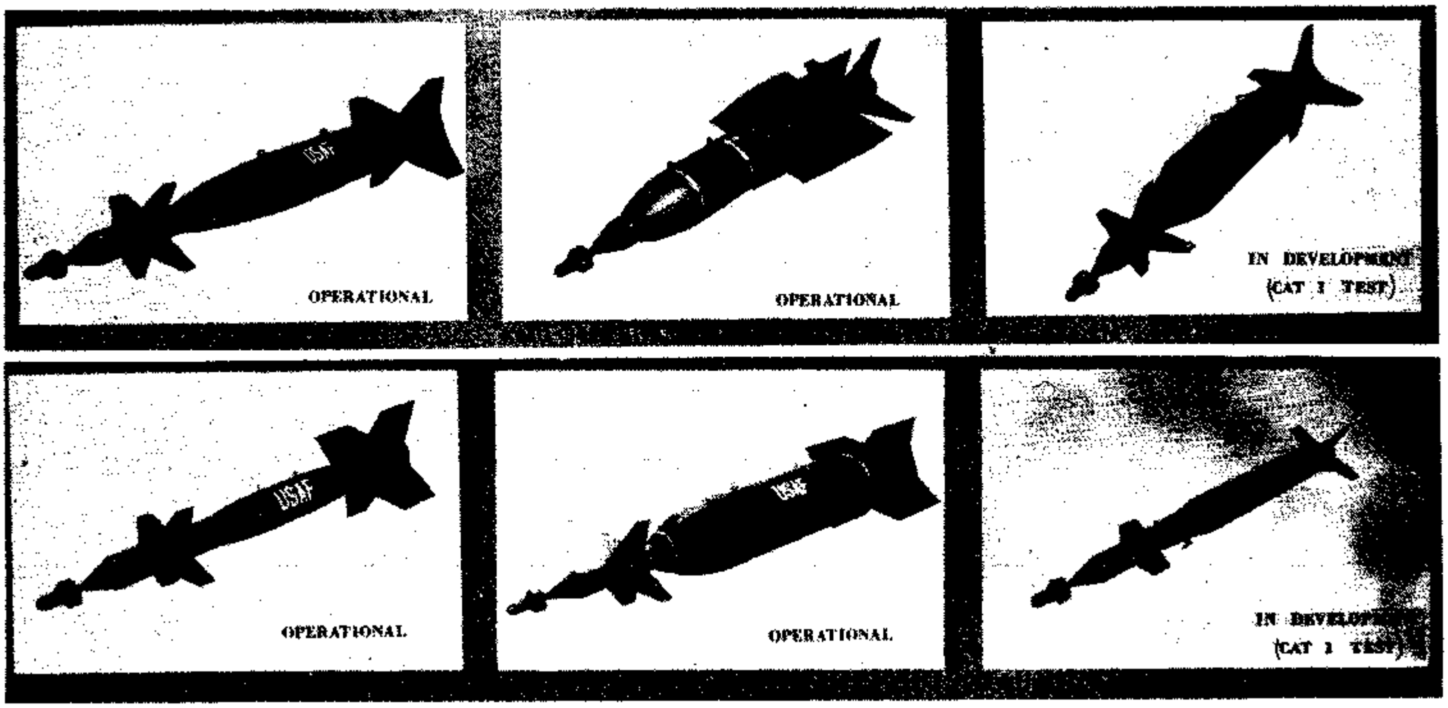
OPERATION:

The guided bomb kit directs the weapon toward a target which has been illuminated by laser energy. The desired target may be selected by the bombing aircraft, a companion aircraft, or a ground observer. The laser energy is reflected from the target and detected by the laser semi-active guidance system. The system processes the information, computes appropriate control commands, and applies these commands to movable surfaces to effect changes in trajectory, thereby guiding the weapon to the target.

The system requires no electrical connection to the unmodified delivery aircraft and is delivered in the same manner as a conventional bomb. There is no requirement for tracking or lock-on before launch, which minimizes the time required for delivery with concomitant reductions in aircraft exposure to hostile ground fire.

DEVELOPMENT:

The Armament Development and Test Centre, Eglin Air Force Base, initiated a competitive evaluation of two laser guidance concepts for standard bombs in 1965. The first laser guided bomb flight took place in April 1965. This evaluation proved the feasibility of the concept and was followed by establishment of the Paveway (Entry No.



Paveway laser guided bombs

1533.311) programme office at Wright-Patterson Air Force Base. Texas Instruments was selected to conduct engineering development to supply additional laser guidance kits for M117 GP bombs.

The remarkable accuracies realized in the feasibility demonstration, using munitions from altitudes out of range of ground fire, led to Southeast Asia evaluations with the first combat release in 1968. These accuracies also led the USAF to initiate a series of contracts to realize the benefits of the basic guidance kit with other munitions.

Since 1965, utilising the laser guidance kit developed by Texas Instruments, two additional GP bombs (MK82 and MK84) and the M118 demolition bomb have been successfully adapted to laser guidance and operationally deployed. Initial evaluations were also begun in 1970 to study application of Texas Instruments' guidance kit to the Rockeye cluster munition. Similar evaluations were initiated in 1971 for application of the kit to the Pave Storm cluster munition. During 1971 both cluster weapons were successfully tested utilising laser guidance.

STATUS:

Four configurations of laser guided bombs (the high and low speed versions of the MK82, the high speed MK84, and the M118) are now operationally deployed with the USN and the USAF. The M117 was initially deployed with the USAF, but is no longer in inventory.

In addition, the low speed version of the MK84 is now in Category II testing, and the Rockeye and Pave Storm cluster munitions are in development testing.

These eight configurations of laser guided bombs all employing the Texas Instruments guidance kit are compatable with the F-4, F-105, F-111, F-100, F-5, A-6, A-7, A-4, A-1, A-37, and B-57 aircraft.

In March 1974 it was reported that Iran had made arrangements with America for the supply of laser-guided bombs and a number (six) of airborne laser target designators. This will make Iran the first nation other than South Vietnam to be supplied with such weapons.

Texas Instruments Incorporated, 13500 North Central Expressway, PO Box 6015, Dallas, Texas 75222, USA.

1772.311

AMERICAN AIR-TO-SURFACE IMPROVEMENT PROGRAMME

DESCRIPTION:

Continued improvements in ground defence capabilities, as demonstrated in the 1973 Middle East conflict, have led the American DoD to embark on a number of programmes and projects to improve the capability to attack surface targets. Fundamental problems such as the extension of technology of precision guidance and stand-off range to provide a large number of aircraft to achieve "one-shot kills" without penetrating a heavily defended terminal area are receiving concentrated study.

Developments to TV-guided glide bombs to give them longer ranges are in progress, and as part of the USAF programme to emphasise conventional attack capability, **Pave Strike** (see **1533.311**, which follows), a sum of $9.4 million was allocated in the FY 1975 Budget for continued development of the Modular Guided Glide Bomb (**MGGB II**). Modifications to be demonstrated in this development will provide stand-off capability and integrate both television and DME guidance. The latter guidance technique is for use with the Airborne Locator and Strike System (**ALSS**), and the Precision Emitter Location and Strike System (**PELSS**), described later. The MGGB II will be compatible with use by USN carrier-based aircraft. A data link which will be appropriate to use in three weapons, Condor, Walleye II ER, and MGGB II is in development. Other forms of guidance are being explored and there are funding allocations for both USAF and USN requirements. Two types of imaging infrared guidance system are to be flight tested. Other captive flight tests will include radiometric correlation guidance which can be used in adverse weather conditions.

Improved kill mechanisms are another priority development area and work is continuing on the perfection of the air-delivered, anti-armour mine **GATOR**, which is for use by all US Forces.

The Modular Weapons concept has the objective of reducing the overlapping proliferation of individual weapons which tends to result from unco-ordinated exploitation of the numerous combinations of guidance, warhead and other aspects of missile technology. An advanced development programme has been set up to test the feasibility of interchangeability through hardware tests of a limited number of existing components in a combination of three warheads and three seekers, giving nine optimised weapon possibilities.

In line with US plans for application to future weapons, flight tests are to be carried out of a low-volume ramjet (**LVRJ**) engine. A power unit of the kind envisaged has the potential of producing missile speeds of Mach 3 to 4 and of operating altitudes up to 100,000 ft (30,480 m), in both air-to-air and air-to-ground roles.

In conjunction with the planned weapon improvements, there are schemes to upgrade existing aircraft with high resolution sensors to improve their weapon delivery capability. The first of these to enter service will be the **Pave Spike** (see **1533.311**) due to become operational this year. It is smaller, lighter and less costly than the similar first generation **Pave Knife** pods which were used with success in SE Asia by both the USAF and USN.

Development is continuing of Forward Locking Infra-red (**FLIR**) sensors for the USN's A-6E and A-7E aircraft, this being linked with the **TRAM** (Target Recognition and Attack Multisensor) project. The A-6E system consists of both TRAM and a laser target designator, while the A-7E TRAM is pod-mounted and contains a FLIR only. Yet another pod configuration containing a FLIR and laser designator is under development for the F-4 and possibly F-111 under the designation **Pave Tack**, as part of **Pave Strike**.

Remotely Piloted Vehicles (**RPVs**) are being closely studied as alternatives to manned aircraft for missions in high threat areas, and the USAF is engaged on a multi-mission RPV development to produce a prototype based on the existing AQM-34 type drone with an interchangeable configuration to suit it for camera or side-looking radar reconnaissance; electronic warfare jamming and seeding decoys; and dropping bombs or launching missiles such as Maverick to strike selected targets.

1533.311
PAVEWAY AIR-TO-GROUND WEAPON DELIVERY SYSTEMS

DESCRIPTION:

The USAF Paveway programme is a very large series of projects undertaken with the main objective of obtaining significantly improved accuracy in the delivery of air munitions, other than guided missiles, against ground targets in Southeast Asia. The weapons concerned are mostly bombs (with or without added homing and guidance systems) and aircraft guns. Of the many techniques tested and adopted, most were based on the use of lasers or other electro-optical devices. Appreciable improvements in accuracy have been achieved by virtue of better target marking from the use of laser designators or other devices, and a reduction of the weapon CEP (Circular Error Probability) area, reportedly to be 90-120 metres diameter. The latter is achieved by the ability of weapons such as Hobo 'smart' bombs (see Entry No. **1097.311**) to compensate, after release, for many of the factors which adversely affect CEP accuracy, such as slight delays in release, inaccurate altitude and air data values, ballistic variations etc.

Numerous separate projects were initiated within the scope of the overall Paveway programme, these are described in the following paragraphs. Many of these techniques were evolved specifically for the Vietnam War, in which the USA is now no longer involved, and some of the Pave programme listed below must be regarded as lapsed. Others will have been superseded, but where status information has been obtained, this is included in the text.

Pave Arrow:

This is a pod-housed system devised to provide pilots with facilities for acquiring laser-marked targets and directing either conventional or laser-guided bombs (see Entry No. **1534.311**) against the targets. The pod contains a laser seeker to which the aircraft gun sight is slaved. The seekers were developed and supplied by Martin-Orlando, and Korad lasers were incorporated in stabilised target designators produced by North American Rockwell for installation in Forward Air Control (FAC) aircraft. Aircraft fitted with the Pave Arrow pod included the F-100.

Pave Gat:

This designation was given to a project in which a Martin B-57 aircraft was equipped with a special Emerson Electric belly turret armed with a 20 mm gun. Gunfire was directed by means of a low-light television camera and monitor, with ranging by laser. The system was delivered to the USAF for flight trials in early 1970.

Pave Hawk:

Little is known of this system which was designed to provide night target marking from a drone. This was a Ryan vehicle and Kollsman also participated.

Pave Knife:

This is a pod-mounted system developed by Philco-Ford under a $3.6 m USAF contract for fitting to F-4D aircraft. The initial award called for six units, and the system bears the official designation AVQ-10. Shared wide-angle optics serve a Westinghouse laser target illuminator and a Dalmo-Victor low-light television camera. Stabilisation is provided. The system provides for night target acquisition and laser designation for attack by Paveway bombs. The USAF carried out tests of methods of slaving the AVQ-10 to the aircraft attack radar. Ranges of up to 12-15 km have been reported.

In November 1972 it was announced that a number of USN A-6A attack aircraft were to be fitted with AVQ-10 pods. The Navy version used a Hughes neodymium laser and a Ball Brothers Research Corporation TV camera, both mounted on a common stabilised platform. The A-6A multimode display in the cockpit was modified by Norden to enable it to accept TV video. This system produced good results in the hands of both the USAF and USN in Vietnam.

Pave Lance:

Pave Lance is a successor to Pave Knife and is similar in concept but with greater night and all-weather capability, and intended for F-111 use as well as the F-4D. A series of five study contracts was awarded by the USAF to Bell Aerosystems, Martin-Orlando, North American Rockwell, Texas Instruments and Westinghouse. Probably no longer active.

Pave Light:

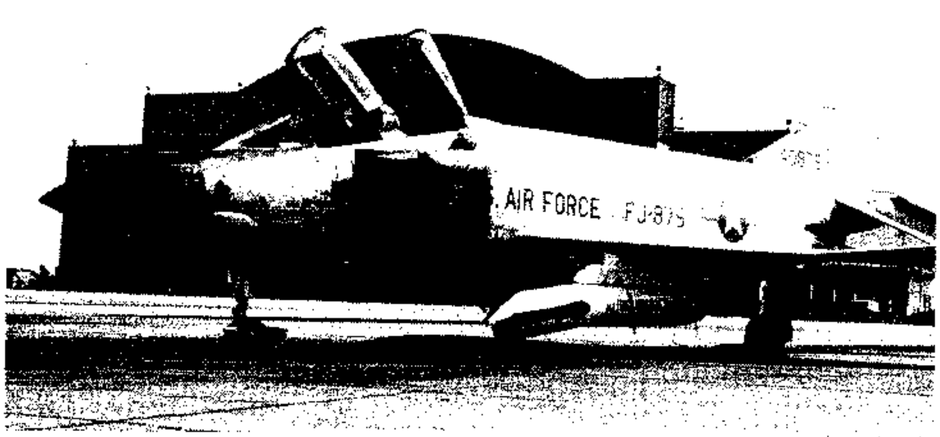
This designation was given to a stabilised laser illuminator with direct viewing arrangements for the F-4 developed by Dynasciences. The project was completed by early 1970.

Pave Mack:

This project has the objective of hitting trucks and ground transport from the air. Target illumination and designation from a FAC aircraft is by equipment similar to that employed in Pave Spot (qv), and weapons considered include Zuni rockets fitted with laser seeking heads. Martin-Orlando received a contract in December 1969 and modified a number of 2.75 in FFAR (Fin Folding Aerial Rockets) to produce what became known as LARS, Laser Aided Rocket System.

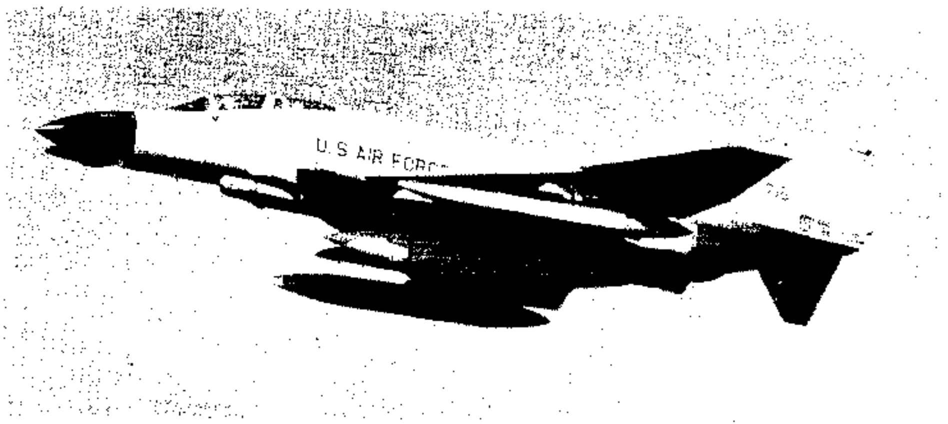
Pave Nail:

Under this programme four OV-10 observation aircraft were modified by LTV Electrosystems for use as night FAC aircraft. The contract awarded in late 1970 provided for options on a further 14 aircraft to be modified. The aircraft were fitted with the Varo, Inc stabilised periscopic night sight developed originally for the Cessna O-2A, and a combined laser range finder and target illuminator. The laser was supplied by Martin Orlando. A Loran navigation receiver and co-ordinate converter were also installed. In operation, the observer uses the sight to detect ground targets.



AVQ-10 Pave Knife low light TV and laser pod for F-4D by Philco-Ford

Pave Knife pod on F-4 aircraft



USAF Phantom carrying Pave Knife pod in the front left Sparrow missile well

using the laser to obtain range data. This is used with the Loran position of the OV-10 aircraft to derive a vector for an accompanying strike aircraft to engage the target. The laser could also be used to illuminate the target for a laser seeking bomb or other weapon.

Pave Nickel:

This is a USAF programme for the use of RB-57 aircraft, and later drones, to locate simultaneously up to 200 radiating sites along the East European boundary of the Warsaw Pact countries. Time of Arrival techniques will be used.

Pave Penny:

This is a laser bombing system for the F-4 to enable it to engage laser-marked ground targets with Paveway bombs. The laser beam can be modulated in coded fashion to offset enemy attempts at light jamming. Night vision facilities are provided in the aircraft installation. Prototype equipment produced by Martin-Orlando began flight test in late 1972.

Pave Phantom:

Phantom F-4D aircraft co-operating with Pave Nail OV-10 FAC aircraft are equipped with a Lear Siegler ARN-92 Loran navigation and computer set. This enables up to eight designated target positions to be inserted into this system in advance of the beginning of the attack. The targets can be engaged without the F-4D crew seeing them.

Pave Pronto:

A system developed for AC-130 Gunships, and employing a Korad laser. Aircraft modification is by LTV Electrosystems.

Pave Spectre:

Another AC-130 Gunship system incorporating low-light television, lasers, and IBM weapon delivery computers.

Pave Spike:

The AN/ASQ-153 Pave Spike pod is a day tracking/laser target designating system that provides F-4D and F-4E aircraft with a self-contained laser guided bomb delivery capability. Pave Spike is being built by Westinghouse under a USAF contract. It has the capability of acquiring, tracking and designating tactical targets from a manoeuvring F-4 at stand-off ranges commensurate with laser guided ordnance. The Pave Spike pod contains an optical subsystem, stabilisation and beam-pointing subsystem, TV tracking sensor, laser designator/ranger, environmental control and associated electronics. The forward nose section of the pod rotates about the roll axis to provide a search capability and the stabilised optics are housed in this section. The complete pod fits into the left front Sparrow missile well of the F-4D/E fuselage. Aircraft mounted elements of the system include a line-of-sight indicator, control panel, range indicator, modified radar control handle and weapons release computer. The AN/ASQ-153 designation denotes Pave Spike configured for the F-4D/E aircraft; the

Tropic Moon III B-57G, converted by Westinghouse for night interdiction

AN/AVQ-23 designation is that of the pod adapted for other types of aircraft.

In mid-1971 Westinghouse was awarded a $5 million contract for 50 sets and the planned USAF total requirement has been reported as more than 120. Prototype flight testing began in September 1972.

Pave Spot:

This system was originally developed by Varo, Inc for USAF Cessna O-2A observation/FAC aircraft. The sensor is a stabilised periscopic night vision sight which is lowered through the fuselage undersurface. In addition to the sighting optics, the rotating turret also contains a Korad laser illuminator.

Pave Storm:

This designation has been assigned to LTV Electrosystems studies of a laser missile-homing weapon, based on the KMU-420 fragmentation bomb. Pave Storm is somewhat heavier and has a Texas Instruments laser-seeking homing head.

Pave Strike:

This designation identifies a group of USAF programmes which, though varied individually, have the common objective of upgrading the capability for conducting precision air-to-ground strikes. The Fiscal Year 1965 Budget allocation for the various projects and developments falling within Pave Strike amounts to about $40 million in all. The principal items covered by this are:

- Modular Guided Glide Bomb II
- EO Glide Bomb (EOGB II), involving modifications to HOBO kit.
- DME Guided SUU-54 Dispenser
- Precision Emitter Location and Strike System (PELSS)
- Deployable Data Base (facilities for putting DME co-ordinates on photographs)
- Airborne Locator and Strike System (ALSS)
- EF-111A (Manned Support Jammer Aircraft)
- Advanced Development of Imaging IR guidance
  - Laser Maverick
  - Pave Tack Pod
  - Multi-Mission RPV.

Further details of some of these weapons and systems will be found in this section and also those dealing with Drones and RPVs, and Reconnaissance Systems

Pave Sword:

This project combines the basic equipment used in Pave Arrow with the laser seeker element slaved to the F-4D attack radar so that the aircraft can be directed at a laser-marked ground target.

Pave Tack:

Pave Tack is the name of a development programme forming part of the USAF Pave Strike programme, and concerned with the development of a FLIR and laser target designator pod for F-4 and F-111 type aircraft.

There are two other Paveway projects on which little information has been obtained:

Pave Eagle II:

All that is known is that the system incorporates a data link and a special purpose drone (QU-22B).

Pave Fire:

This is described as used on specially equipped F-4D aircraft

Although not bearing Paveway designations, there are a number of other programmes having similar objectives. These are briefly described in the following paragraphs.

Blind Bat:

This system is carried by some AC-130 Gunships. The equipment is similar to that used in Pave Nail and Pave Spot FAC aircraft, and the operational method also is similar, Loran target co-ordinates being transmitted to accompanying Pave Phantom strike aircraft.

Long Knife:

This is a new system due for flight testing this year in a USAF F-4D. Housed in the same pod as Pave Knife, it is to have increased accuracy and improved stabilisation. Sensors will be a Bali Brothers Research Corporation low-light level TV camera and an International Laser Systems laser designator.

Tropic Moon 3:

This programme involved equipping 12 Martin B-57G aircraft for night interdiction operations by Westinghouse for the USAF. Special equipment included the AXQ-5 television weapon delivery system, electro-optical target identification and tracking, and other sensors.

1301.321
HARPOON (AGM-84A) AIR-TO-SURFACE ANTI SHIPPING MISSILE

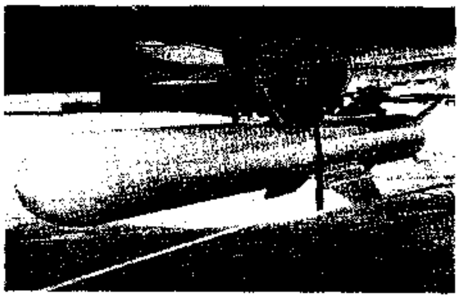
DESCRIPTION:

Harpoon, originally designated as ALSAM (Air Launched Ship Attack Missile), is an all-weather anti-ship missile for use against surfaced submarines, patrol craft, destroyers and larger vessels, merchant ships and trawlers.

The missile will be capable of being air-launched or, with the addition of a rocket booster, ship-launched. This latter version will supplement existing shipboard missile systems and will become operational on those ships which do not currently have a missile capability. McDonnell Douglas and the US Navy are adapting Harpoon for launch from submerged submarines also. Further details of Harpoon in these versions will be found in Entries Nos. **2641.221** and **2797.421**.

Approximate dimensions are length 800 cm, body diameter 30 cm, span 100 cm, and the

Air launch version of Harpoon beneath USN P-3 Orion aircraft



Harpoon in air-launch configuration

weight 900 kg. Ship launched versions will have an additional motor, with four fins, attached to the rear of the missile. Mid-course guidance will be performed by a system being jointly developed by IBM and Lear Siegler: the former providing the digital processor, and the latter the strap-down sensor/guidance sub-system. This technique uses computer techniques to process the data from non-gimballed gyros to sense missile velocity in three axes and derive control signals from this information. It is anticipated that this will be comparable to the inertial guidance technique but simpler and less costly.

The missile will employ an active radar terminal guidance seeker.

The programme is currently in advanced development. McDonnell Douglas received a $60 million contract in June 1971 and the first two test models were delivered in March 1972, one to the US Navy Naval Missile Centre at Point Mugu, California, and the other to the NASA Lewis Research Centre, Cleveland, Ohio. At Point Mugu, the first model was used for aerodynamic tests of the missile carried by a P-3 aircraft, and at the Lewis Research Centre sustainer engines developed by Garrett A Research and Teledyne CAE Division underwent wind tunnel tests installed in the second Harpoon test vehicle. Six more test models were delivered for separation tests and shipboard handling studies. For Fiscal Year 1974 the US Navy sought $19 million for procurement, plus $66.6 million for continued research, engineering and development. The Harpoon system is planned to enter operational service in 1975. The Fiscal Year 1975 Budget called for $78.2 million for the procurement of an initial production of 150 Harpoons.

Harpoon immediately after air launch from P-3

1123.311
STANDARD ARM (AGM-78B) ANTI-RADIATION MISSILE

DESCRIPTION

Air-to-ground passive radar homing missile for the destruction of surface-to-air missile battery radars. The system consists of a modified Standard (RIM-66A) medium-range missile for delivery by current high-performance aircraft equipped for the detection, identification and acquisition of the radar target. Each aircraft can carry up to four missiles.

More recently, this weapon has been adapted to two further roles – to provide Standard-equipped ships, and those previously without a missile capability, with a surface-to-surface weapon system. These programmes are described in Entries Nos. **2808.221** and **2669.221**.

The AGM-78B is propelled by a dual-thrust solid-propellant rocket motor and a conventional high-explosive warhead is carried. Speed is in excess of Mach 2, and range is estimated at over 25 km. Principal characteristics are: length 457 cm, diameter 30.5 cm, and weight 816 kg.

OPERATION:

System operation is initiated by reception of hostile radar transmission by the aircraft. The received signal is processed to extract target location, identification, and threat data. A missile is then launched and homes on to the source of radar transmission. The dual-thrust motor of the missile enables it to follow a variety of pursuit courses to the target. Missile warhead detonation, in addition to destroying the target, activates a visual marker to denote the impact area for follow-up strikes.

The Target Identification and Acquisition System (TIAS) installed in the aircraft will incorporate quite sophisticated techniques to counter the various methods adopted by the opposing force to confuse passive radar homing missiles by regular or irregular switching off of the ground radar etc. TIAS is the responsibility of IBM and the system incorporates an IBM 4-pi digital computer. Among the functions of this unit will be the computation of a trajectory for the AGM-78B on the basis of all past received data in the event of the target radar being turned off. It has been reported that TIAS will only be installed in US A-6A aircraft because of weight limitations in other types deploying the Standard ARM (F-105 and F-4). It has also been stated that a smaller, lighter version of TIAS is under development.

USAF aircraft are reported to be using an advanced version of the Wild Weasel radar warning and homing system for target identification and acquisition purposes. The processor to be used with the ECM system for Standard ARM operation has yet to be selected.

DEVELOPMENT:

Design studies for the Standard ARM, and the first development contracts, were initiated in 1966. Flight tests took place in 1967 and were completed in the following year. Full production began in 1968. Contracts awarded to the main contractor, General Dynamics, total over $100-million.

STATUS:

The AGM-78B Standard ARM entered operation services in 1968 with F-105F and A-6A aircraft, but deployment with F-4 aircraft appears to be lagging, and is presumably dependent upon the completion of development of a suitable TIAS for this type.

Production began in Fiscal Year 1970 on the AGM-78C version, and development is continuing on the AGM-78D model. The US Navy currently plans arming the EA-6B and E-2C electronic aircraft with this missile.

The US Navy is also developing the missile for adaptation as a surface-to-surface weapon for ship-borne applications. By mid-1971 several test firings from patrol gunboats had been made.

The Standard ARM (AGM-78) has been used as the basis of a new weapon system XAGM-97A, Seekbat, intended for air-to-air use to counter the Soviet MiG-25 Foxbat interceptor.

Standard ARM carried by A-6 aircraft

1769.311
HARM – HIGH-SPEED ANTI RADIATION MISSILE

DESCRIPTION:

The HARM programme has as its objective the development of a new anti-radiation missile for use in defence suppression and similar operations, and which offers performance improvements over the existing Shrike (**1102.311**) and Standard ARM (**1123.311**). Higher speed, faster reaction, and a more destructive warhead are the likely priority improvement areas. Other desired characteristics which have been specified are: relatively low cost, integrated avionics and Electronic Warfare systems, integrated circuit construction, latest ECCM, weight of about (300 kg), an improved propulsion system, an improved frequency coverage.

DEVELOPMENT:

First contracts in support of HARM research and development were awarded during 1972. Among them were the following: Texas Instruments, guidance and avionics; Hughes Aircraft, systems analysis and guidance support; Itek, AN/ALR-45 radar warning receiver modifications; Lockheed, system studies; Dalmo-Victor, modification of DSA-20N signal analyser; Stanford Research Institute, analysis. The Fiscal Year 1975 Budget called for a F.Y. 1974 Supplemental funding of $4.0 million to accelerate HARM development and another $18 million for continued development as part of the 1975 Budget's defence suppression effort.

2831.311
TOW AIR-TO-SURFACE APPLICATION

DESCRIPTION:

As noted in the main description of the TOW anti-tank weapon system (**2830.111**), this weapon, like several other anti-tank weapons, can be used as armament for fighting helicopters.

Both the gunner's sight and the optical sensor are mounted on a specially developed gyrostabilised platform, which gives the tracking and control system a constant reference surface. The sight is pointed at the target by means of a joy-stick.

The anti-armour version of the Bell Huey Cobra is equipped with the XM-26 airborne TOW system, and up to four 2-round modular TOW launch pods can be carried, while still leaving the inboard pylons free for rocket or 20 mm minigun pods. The XM-28 turret with a 7.62 mm minigun and 40 mm grenade launcher is retained. In addition to stabilised optics and a missile tracker, the modified XM-26 sight has provisions for a laser range finder. Helmet sights allow the crew to control the turret directly or provide target acquisition for the stabilised optics.

STATUS

In 1972 the concept of TOW-armed helicopters being employed specifically as an anti-tank force for defence against armour attacks was tested under real conditions in SE Asia and in simulation exercises in Europe. In both cases very promising results were reported.

In Vietnam, TOW-Cobra helicopters were used against abandoned tanks and moving vehicles with the principal objectives of obtaining data on practical operating aspects and weapon performance under combat conditions.

The trials held in West Germany were simulations, were far more elaborate and were run to build up statistical information relating to various tactical situations as applied to both the attacking (armour) side and the defending force (TOW-Cobras and spotter/director helicopters).

Units of the West German, Canadian and American forces took part, the Bundeswehr providing the attacking formations of Leopard tanks. All participating vehicles and aircraft were equipped with Solartron Simfire laser fire simulation systems linked to comprehensive recording and scoring systems. The exercises consisted of ten trials each of delay, defence and break-through situations in which two TOW-Cobras were matched against a platoon of Leopards reinforced with a US Army Vulcan air defence unit. These 20 trials were repeated using two OH-58 scout helipters and one TOW-Cobra. The latter combination of helicopters proved most successful. The statistical outcome of the exercises was a total of 14 helicopters (10 TOW-Cobras and 4 Scouts) lost against 167 tanks and 29 Vulcan units disabled.

HELLFIRE TACTICAL AIR-TO-SURFACE MISSILE

DESCRIPTION:

HELLFIRE is an acronym (Heliborne, Laser, Fire and Forget) used to describe a new laser-guided missile under development by the US Army. The missile is said to be smaller than TOW, but with a much greater range. It is being developed for the Army's Cheyenne attack helicopter but could also be mounted aboard armoured personnel carriers for use with ground combat units as an indirect fire weapon. The missile's terminal guidance system will permit a "launch and leave" capability enabling launching aircraft to reduce significantly their exposure to the target.

In late 1971, General Dynamics unveiled its proposed system to meet the Hellfire requirement, under the designation MRAM – Multi-mission Redeye Air-launched Missile. This system uses a modified version of the Redeye heat-seeking missile, two of which would be carried in each of two re-usable launch pods attached to the helicopter.

A similar proposal for a version of the Shillelagh anti-tank missile has been made by Philco-Ford, and North American Rockwell has suggested a development of the Hornet (Entry No. **1097.311**) which was originally intended for anti-tank operations before it became a test-bed vehicle for new guidance systems. In January 1972 the US Army Missile Command invited industry proposals for a ground laser target designator for use with Hellfire, and requests for an airborne version were issued soon after. Although initial effort was directed towards the use of laser guidance, the programme has since become increasingly concerned with the development of a modular weapon capable of using a variety of guidance techniques. The Fiscal Year 1975 Budget sought $6.3 million for the development of a dual RF/IR Seeker, and another $9.0 million for further development and test work on the missile.

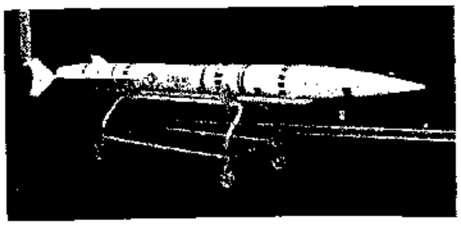
1773.311
SAGMI (SURFACE ATTACK GUIDED MISSILE)

DESCRIPTION:

One of several classified defense-suppression concepts sponsored concurrently by the USAF, the SAGMI (Surface Attack Guided Missile) was developed and demonstrated successfully by Beech Aircraft Corporation during 1971-1972, under the direction of the Air Force Armament Laboratory at the USAF Armament Development and Test Center, Eglin Air Force Base, Florida. Derived from the Beech AQM-37A missile target, SAGMI was funded under total expenditures of only $2.3 million to cover system definition, construction and flight demonstrations. Its configuration is shown in the accompanying illustration.

The programme objective was a long-range supersonic defense-suppression weapon with "fire-and-forget" capability, which could be used in conjunction with conventional munitions.

Power plant of SAGMI is a single American Machine and Foundry LR64 (modified) liquid-



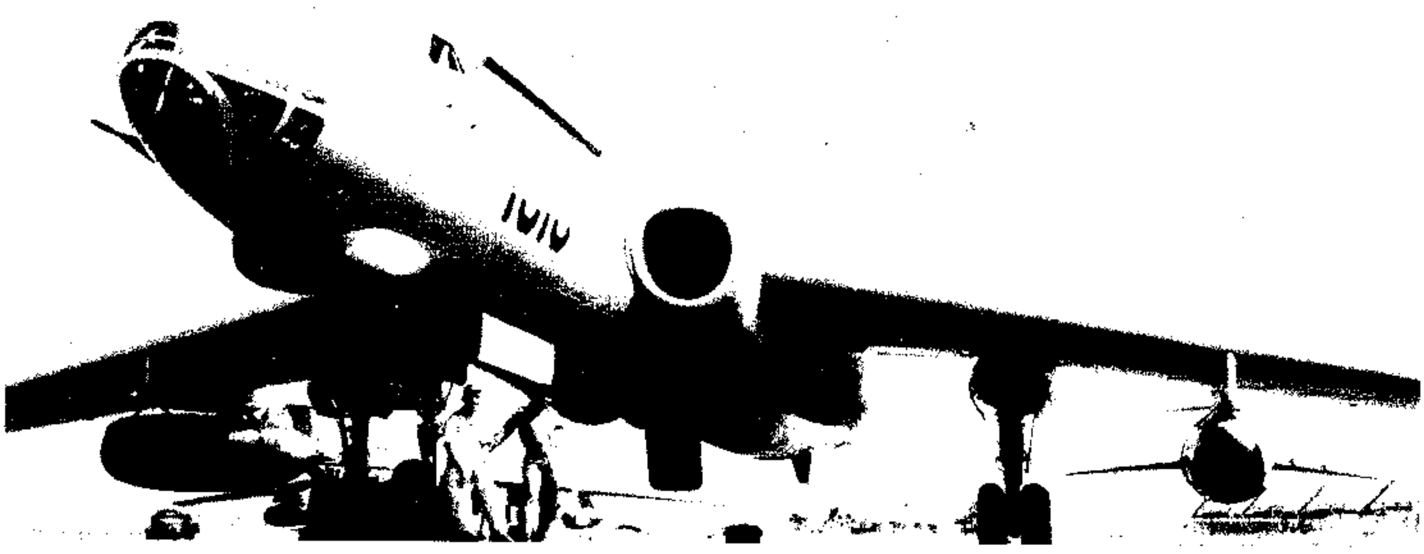
SAGMI (Surface Attack Guided Missile) developed by Beech Aircraft Corporation propellant rocket engine. The guidance technique was developed as part of a separate concurrent project and remains classified. According to reports, it enabled SAGMI to achieve outstanding terminal accuracy.

Dimensions of SAGMI are: length 5.23 m, diameter 33 cm, and wing span 1.02 m.

MANUFACTURER:

Beech Aircraft Corporation, Wichita, Kansas 67201, USA.

THE UNION OF SOVIET SOCIALIST REPUBLICS



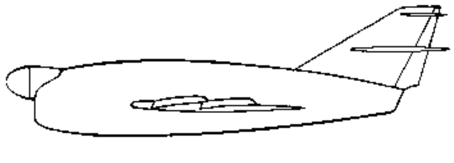
Tu 16 Badger loaded with two Kennel air-to-surface missiles

1148.311
KENNEL (AS-1) AIR-TO-SURFACE MISSILE

DESCRIPTION:

Kennel is the NATO code-name assigned to a Soviet stand-off air-to-surface weapon carried by Tu-16 (Badger) aircraft, one beneath each wing. Estimated dimensions are: length 8.5 m, wing span 4.9 m. It is powered by turbojet motor, and its general appearance is rather similar to that of the Ryan Firebee drone. Externally, Kennel is almost identical with the Samlet coastal defence missile, and the two weapons may in fact be versions of the same missile. Estimated range is up to 50 nautical miles (90 km).

A probable operational role is anti-shipping strike missions, and external evidence of electronic equipment carried by Kennel missiles suggests that either beam-riding radar or radio command link guidance is used for the major portion of the trajectory, with either passive or active radar homing for the terminal phase. The parent Badger aircraft are provided with at least two radars on the underside of the fuselage which could serve such a mode of operation.



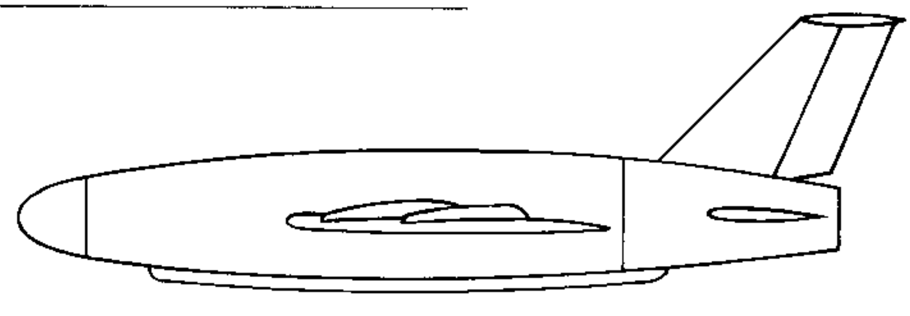
Kennel (AS-1)

In addition to the Soviet forces, the Badger/Kennel combination has been supplied to the Indonesian and Egyptian Air Forces.

1149.311
KELT (AS-5) AIR-TO-SURFACE MISSILE

DESCRIPTION:

Kelt is the NATO code-name of a Soviet air-to-surface weapon, first seen by a Tu-16 Badger bomber aircraft. It has superficial but pronounced similarities with the Kennel (Entry No. **1148.311**) which also is used with the Badger, and with the Styx shipborne surface-to-surface missile (Entry No. **1155.221**). Estimated dimensions of Kelt are length 9.4 metres and wing span about 4.6 metres. The fuselage centre-body and wings of Kelt appear to be the same or very similar to those of Kennel, while the nose section (and presumably the guidance system it carries) of Styx is employed. A rocket propulsion motor is used and the tail control surface arrangements of Kelt differ from both those of both Styx and Kennel. Western estimates of range vary between 160 km and more than 320 km, but a figure of about 180 km seems most likely.



Kelt (AS-5)

AIR-TO-AIR-MISSILES

FRANCE

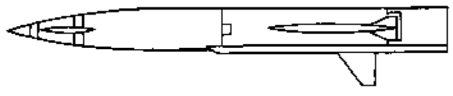
1178.331
R.511 AIR-TO-AIR MISSILE

DESCRIPTION:

Air interception missile using semi-active radar homing guidance. Principal characteristics are: length 309 cm, diameter 26 cm, weight 184 kg, wing span 1 m. Propulsion is by two-stage solid-fuel motor and range is about 8-10 km. The radar homing head is produced by Thomson-CSF.

OPERATION:

The fire control radar of the launch aircraft is used as a target illuminator radar for the missile homing head which derives guidance signals for the missile autopilot from reflected radar energy received from the target.



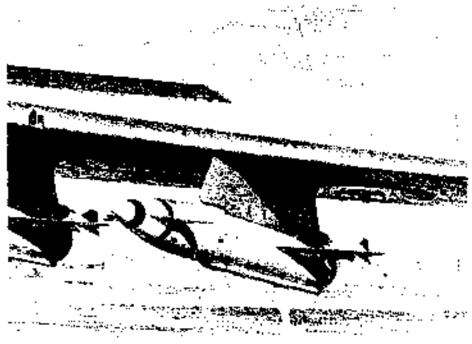
R.511

STATUS:

The R.511 is still operational with the French Air Force and must now be considered obsolescent.

MANUFACTURER:

Engins Matra, 49 rue de Lisbonne, Paris 8, France.



R.511 air-to-air missile

1176.331
R.530 AIR-TO-AIR MISSILE

DESCRIPTION:

All-weather all-aspect air-to-air missile system produced with alternative semi-active radar homing or infra-red guidance heads. Principal characteristics are: length 328 cm, diameter 26 cm, wing span 110 cm, weight 195 kg. Maximum speed is Mach 3.0 and range is 18 km. Apart from the homing heads the two versions of the R.530 are identical. Propulsion is by a two-stage solid-propellant Hotchkiss-Brandt motor of 8,500 kg static thrust. Either of two types of high explosive warhead produced by the same concern, and weighing 27 kg, can be fitted.

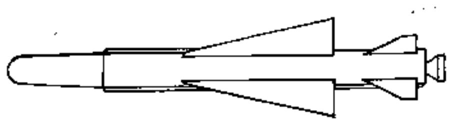
OPERATION:

The infra-red homing version is stated to be capable of successful interceptions from any aspect, relying upon heat from either the jet engine and its exhaust from the rear quarters and local airframe hot-spots by aerodynamic heating when attacking from the front. This mode of operation is intended mainly for high altitude interception in clear air or at low level beneath cloud.

The semi-active radar homing head is produced by Electronique Marcel Dassault under the designation AD26 and this is for use with an X-band target illuminating radar (normally the launch aircraft's fire control radar installation). Use of the proportional navigation method of guidance in the AD26 head permits a wide missile firing range and good hit probability against manoeuvring targets. Anti-jamming devices of an unspecified nature are incorporated which are claimed to make it almost immune from current ECM techniques and those foreseen for the near future.

The radar homing head is able to lock on data stored during the passage of the altitude echo through the target 'window'. For maximum simplicity and economy, the circuitry used to harmonise the AD26 with the fire control radar is grouped in a harmonisation pack which is installed in the parent aircraft. Pre-launch operations are performed automatically and consist of: (1) harmonisation of the AD26 head with the radar, (2) prepositioning of the aerial in the target direction, (3) pre-setting of homing head circuits to match the characteristics of the returned echo signals, (4) computation of fire control parameters for a collision course.

During the homing period, the AD26 generates the flight control signals for the stabilisation and guidance of the missile to the target. Weight of the AD26 head is 18 kg (including skin and radome) and its range is in excess of 10 km. Construction consists of two main modules. The foremost consists of gyro-aerial RF head and part circuitry, and the rear portion is a structure of three light alloy compartments containing the power supplies and other circuits.



R.530

Matra R.530 as carried on French Navy Crusader

Matra R.530 on Mirage

DEVELOPMENT:

Design and development work on the R.530 started in 1958 with Engins Matra acting as main contractor to the French Air Ministry. Entry into service was in 1963.

STATUS:

The R.530 is in full production and used with the Mirage IIIC, Mirage IIC and Crusader F-8E of the French Naval air arm. In addition to the French Forces, other users include the Australian, South African and Brazilian Air Forces. The manufacturers state that twelve nations have been supplied with this weapon. Production of the R.530 is expected to cease in 1976.

MANUFACTURERS:

Matra, 2 rue Louis Breguet, 78-Velizy -Villacoublay, France.

AD26 Homing head – Electronique Marcel Dassault, 55 Quai Carnot, 92-Saint Cloud, France.

Infra-red homing head – Société Anonyme de Télécommunications, 41 rue Cantagrel, Paris 13, France.

1349.331
SUPER 530 AIR-TO-AIR MISSILE

DESCRIPTION:

This is a developed version of the Matra R.530 weapon, intended to meet the higher speed and altitude performance requirements of the next-generation of interceptor aircraft.

The Super 530 is a high performance interception missile which succeeds the 530, with twice the possibilities in range and acquisition distance.

With a design concept for reaching targets flying at very high altitude and at high mach numbers, it comprises: a "long-wing" of low width, which gives it exceptional aerodynamic qualities, in particular in the area of load factors at altitudes greater than 70,000 feet; a motor with a very high acceleration rate, which allows the interceptor aircraft to fire with vertical separations of more than 10,000 feet.

The Super 530 is equipped with an electromagnetic homing head developed by Electronique Marcel Dassault.

This all-weather operational missile is under development for the French Air Force. Series production is planned to begin from 1977 onwards.

DEVELOPMENT:

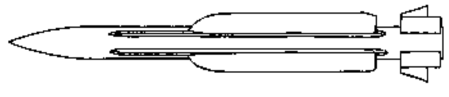
The first test firing (controlled but unguided) of the Super 530 was made after satisfactory ramp testing of a mock-up.

STATUS:

Existence of the Super 530 development programme was first publicly revealed at the Paris Air Show in May 1971. It was then stated that this missile will arm French Mirage F1 and other interceptors.

MANUFACTURER:

Engins Matra, Avenue Louis-Breguet, 78-Velizy-Villacoublay France.



Super R.530

1348.331
R550 MAGIC AIR-TO-AIR MISSILE

DESCRIPTION:

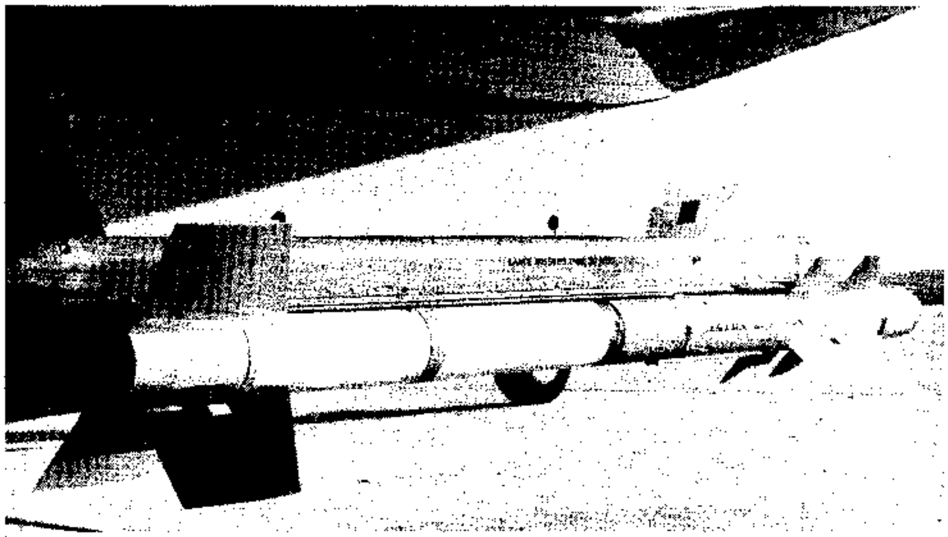
The Matra R550 Magic is a new air-to-air missile designed for 'close-combat' operations (from less than 500 m to more than 6 km), with consequent emphasis upon the ability to withstand high load factors imposed by the severe manoeuvre demands required. The general configuration of the weapon is shown in the accompanying photograph, and the estimated weight is approximately 80 kg. Length is 250 cm, body diameter 26 cm, and maximum span 65 cm. Propulsion is by a solid rocket motor, and operational range is reported to cover from 200 m, or less, to as much as 10 km. Twist and steer control of the missile is effected by the canard arrangement of fins at the forward end of the weapon. An SAT infra-red homing head provides guidance, and the special launch mount houses a liquid nitrogen container to provide cooling for the IR sensor.

DEVELOPMENT:

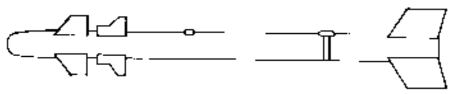
Development was initiated in 1968 and the first firing took place on January 11, 1972 when a CT-20 target drone making a tight turn was successfully engaged by an R.550 Magic launched from a Gloster Meteor test aircraft. A total of about 30 launches are envisaged in the course of development. Ten successive firings were made at the end of April, giving highly satisfactory results.

STATUS:

The R550 was first revealed at the 1971 Paris Air Show and was at the early development stage at that time. It is planned to replace Sidewinders with this missile on French Air Force and Navy interceptors. Although not intended for delivery before 1975, negotiations are taking place and MATRA has recorded three large orders from unspecified foreign air forces. The first aircraft launch under representative conditions was made in late 1973 from a Mirage III against a specially modified C20 target drone. Operational evaluation is being carried out by the French Air Force during 1974.



Matra R.550 Magic close combat missile



R.550 Magic

MANUFACTURER:

Engins Matra, Avenue Louis-Breguet, 78 Velizy-Villacoublay, France.

GERMANY (FEDERAL REPUBLIC)

1738.331
VIPER AIR-TO-AIR MISSILE

DESCRIPTION:

The Viper air-to-air missile has been developed to meet the requirements of the West German Bundeswehr and is intended as a Sidewinder replacement. Although the Viper is clearly based on the Sidewinder, in comparison with that missile a number of technological improvements have been embodied to provide a broader operating spectrum, particularly in respect of target acquisition and range, manoeuvring performance, launch conditions, and hit probability. Besides the enhanced capabilities for target acquisition, Viper also offers extended mission range, especially in low-level and dog-fight' engagements. It can be employed from large off-the-tail angles and from short ranges, restricted only by the necessary safety margin.

The improved mission capabilities are essentially obtained by the following measures:

New infra-red seeker with increased sensitivity, enlarged look angle, and increased tracking rate.

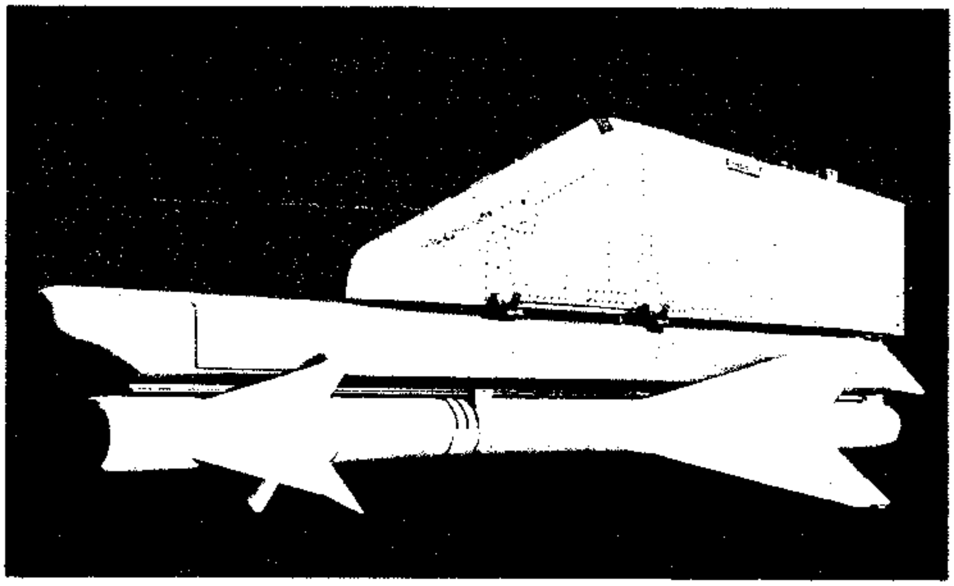
Strengthened fin actuator and improved control surface design.

Improved technology rocket motor.

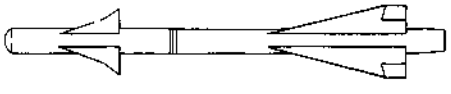
Improved aerodynamic design.

Extended target acquisition capabilities by means of acquisition unit in launcher.

The launcher attachment combines the functions of a housing for missile pre-launch equipment and as the support and release mechanism for the weapon. Equipment contained within the unit includes a cooler for the missile homing sensor, power supply, and certain guidance circuitry. For some combat conditions, the launcher is equipped with its own infra-red detector and search unit to provide target acquisition facilities for the missile homing head. This autonomous mode of operation could serve as either a standby mode or as a means of multi-target engagement if used in conjunction with other missiles using radar homing.



Viper air-to-air missile with launcher attachment containing separate IR target acquisition system and cooling pack



Viper

As can be seen from the accompanying illustration, Viper bears a close resemblance to Sidewinder in external appearance. It is made up of five main components: target seeking guidance head, warhead, proximity sensor, rocket motor, and cruciform tail fins with in-built rollerons at the tips.

DEVELOPMENT:

Development of Viper is being undertaken by Dornier as general manager of the programme, in co-operation with Bodenseewerk, with an integrated project management team.

STATUS

The prototype missile should be ready for flight test at the beginning of 1975. Entry into service is scheduled for 1977, and the F-4F and MRCA are among the aircraft types to carry this weapon.

MANUFACTURERS:

Dornier GmbH, Friedrichshafen, Bodensee, West Germany.

Bodenseewerk Gerätetechnik GmbH, Überlingen/Bodensee, West Germany

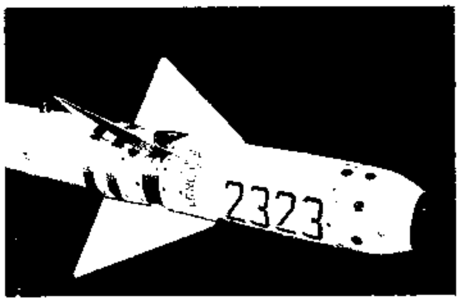
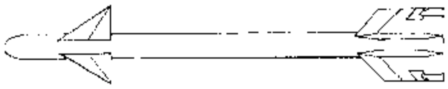
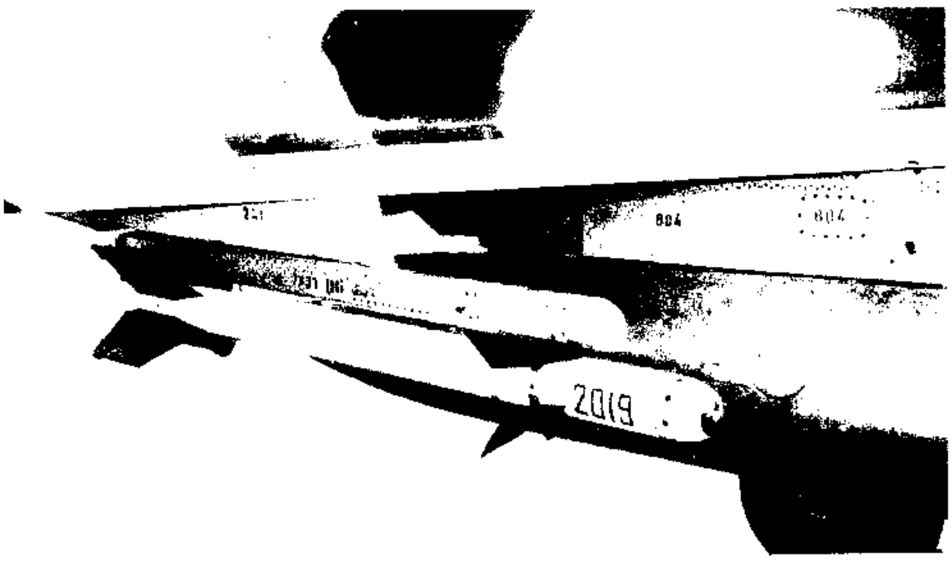
Shafrir infra-red homing air-to-air missile



Close-up of fore-end of Shafrir, showing control surfaces, fuses, and homing head



Shafrir



Shafrir missile on aircraft, showing adaptor mount

1659.331
SHAFRIR AIR-TO-AIR MISSILE

DESCRIPTION

Shafrir is an air-to-air, infra-red homing missile for use against high performance aircraft at heights up to 18,000 m (60,000 ft). It is a relatively small missile, 16 cm diameter and 260 cm long, with pneumatically-operated control fins at the fore-end and stabilising surfaces at the rear. The latter are fitted with the gyroscopically-actuated tabs found on the Sidewinder and Soviet Atoll missiles, for roll stabilisation. Approximate launch weight is 93 kg, of which the warhead accounts for 11 kg. Contact and proximity firing of the warhead are provided.

Simplicity was a major design objective, and both missile and aircraft-fitted elements of the Shafrir weapon system have been kept to the minimum. Electronics are solid state. Apart from the firing circuit, no aircraft-installed equipment is needed.

The missile and its launcher are mounted under the wing of the aircraft and attached to a specially-designed adapter.

OPERATION:

Firing of Shafrir is on a "see-and-shoot" basis. When a target is detected within the firing range, an audio signal is heard and an indicator light in the cockpit is automatically operated. This indicates that the missile launch button can be used. From this point, the guidance system is completely independent of the launching aircraft.

DEVELOPMENT:

Development was started in the mid-1960s by Rafael, the Israeli Armament Development Authority on behalf of the Israel Defence Forces. The development programme was concluded by the end of the 1960s, and production was commenced.

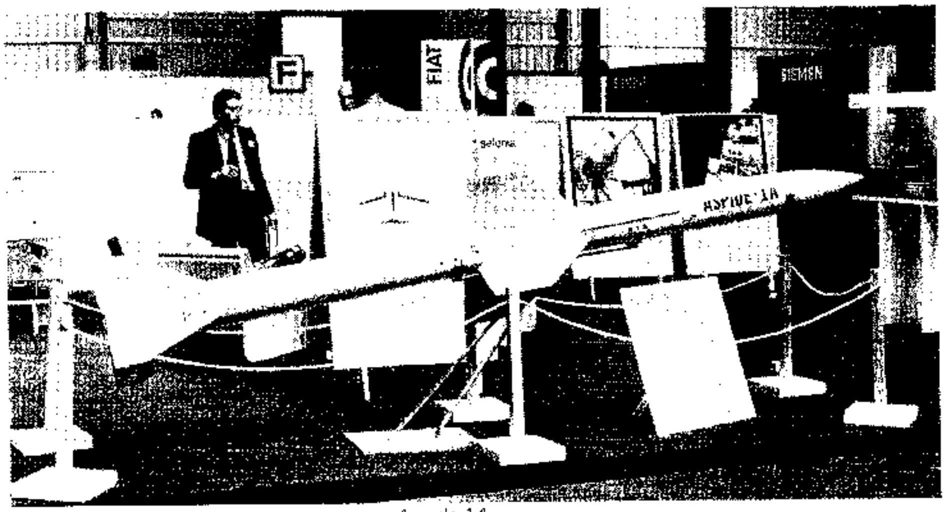
STATUS:

Shafrir has been launched in air combat with a high kill ratio on numerous occasions, according to official Israeli sources.

MANUFACTURER:

Rafael Armament Development Authority, Ministry of Defence, PO Box 2082, Haifa, Israel

ITALY



Aspide 1A

1656.331
ASPIDE MULTIROLE MISSILE

DESCRIPTION:

Aspide is a high performance multirole missile being developed for operation at all altitudes against a wide number of target types, and the Aspide-1A is optimised for air-to-air and surface-to-air missions. It is based on the use of a semi-active radar guidance system which will ensure all-weather and all-aspect operation.

The Aspide-1A was first shown in public at the 1974 Hanover Air Show when it was seen to have a configuration closely resembling the Sparrow missile it is to replace. Principal characteristics are length 3.7 m, body diameter 20.3 cm, wing span 100 cm (air-to-air) or 80 cm (surface-to-air), fin span 80 cm (a/a) or 64 cm (s/a), launch weight 220 kg, burn-out weight 163 kg. Propulsion is by means of a single-stage solid-propellant motor which will give speeds of more than Mach 2.5 in the surface-to-air role.

Present plans are to employ the Aspide-1A with the F-104/S interceptor and its successors (Entry No. **8052.302**); in the Albatros naval point defence weapon system (Entry No. **1551.281**); and in the Spada ground-based low altitude air defence system (Entry No. **2250.131**). In the first two systems, Aspide-1A will replace the Sparrow III (AIM 7E) missile currently employed.

Technical areas in which major development effort has been placed are seeker range, sub-clutter visibility, the fusing system, multiple target effectiveness, ECCM capabilities, functional modularity of construction, reliability and ease of maintenance. Thin-film microwave circuitry developed by Selenia is incorporated in the design.

DEVELOPMENT

Development was started in late 1969 and the contracting agency is the Italian Air Force.

STATUS

Manufacture of the first batch of prototypes was well advanced by early 1974, with flight tests programmed from June 1974. The R and D and evaluation programmes, including surface-to-air and air-to-air flight tests, will be completed by 1975 and production deliveries are scheduled to start during 1977.

MANUFACTURERS:

Prime Contractor – Selenia-Industrie Elettroniche Associate SpA, Via Tiburtina Km. 12.400 Rome, Italy.

Sub-Contractors – SNIA – VICOSA SpA, Rome; Microtecnica SpA, Torino; E. SAG SpA, Genova; Nuova SACA SpA, Brindisi; Aster SpA, Milano.

JAPAN

1187.331
MITSUBISHI AAM-1 AIR-TO-AIR MISSILE
DESCRIPTION:
Few details have been disclosed of the air-to-air missile which is replacing the Sidewinder on F-86F and F-104J interceptors of the Japanese Air Self Defence Force. Guidance is understood to be by infra-red homing
STATUS:
It has been reported that the AAM-1 had already entered operational services by 1969, and a total planned production of 330 units had been delivered by late 1971.
MANUFACTURER:
Mitsubishi Heavy Industries Ltd, 5-1, Marunouchi 2-chome, Chiyoda-ku, Tokyo 100, Japan.

1188.331
MITSUBISHI AAM-2 AIR-TO-AIR MISSILE
DESCRIPTION:
The AAM-2 is under development as a successor to the AAM-1 air-to-air interception missile. The newer weapon is reported to have collision course interception capability, where the AAM-1 was limited to pursuit course attack. No other details are available.
MANUFACTURER:
Mitsubishi Heavy Industries Ltd. 5-1 Marunouchi 2-chome, Chiyoda-Ku, Tokyo 100, Japan.

SOUTH AFRICA

1535.331
SOUTH AFRICAN AIR-TO-AIR MISSILE
DESCRIPTION:
Very few details of this weapon have emerged since the announcement in 1969 by the South African Minister of Defence, Mr P. W. Botha, that an air-to-air projectile had been developed as a purely South African venture. Development had been in progress since 1966, and at the time of the Minister's statement it had recently been successfully tested at the Republic s St Lucia missile range and was nearing production status. In September 1971 the South African Air Force announced the successful engagement of a Mach 2 target with a missile launched from a Mirage III aircraft. The target was said to have been hit three seconds after launch. An announcement was made in late 1972 that initial production of this weapon had started.

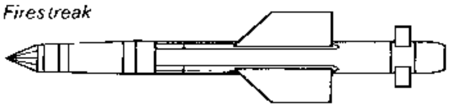
THE UNITED KINGDOM

1079.331
FIRESTREAK AIR-TO-AIR MISSILE
DESCRIPTION:
Infra-red homing, air-to-air weapon for use against high speed aircraft. All-altitude operation is possible against manoeuvring targets. Rear hemisphere engagement zone.

The missile has a cylindrical metal body carrying cruciform wings, behind each of which is a small control surface near the tail. Dimensions are: length 3.19 m, diameter 22.2 cm, wing span 75 cm. Launching weight is 136 kg and operating range is 1.2-8 km. Speed, over Mach 2. Unofficial weight for the warhead is 22.7 kg. The infra-red target tracker sensor is housed in the nose of the missile and protected by an 8-sided pyramidal nose-cone of flat glass plates.

In addition to Firestreak installations engineered to a specific aircraft type, it is available with an aircraft pack containing associated control systems, electronics and supplies, suitable for use with a wide range of aircraft types.

Firestreak



STATUS:
Firestreak has been used to equip RN Sea Vixens, and RAF Javelin and Lightning aircraft. It remains in service with the last of these types. Production ceased in 1969 and there is a phased replacement of Firestreak by Redtop.
MANUFACTURERS:
Hawker Siddeley Dynamics Ltd, Manor Road, Herts AL10 9LL, England.

Firestreak air-to-air missile carried by Lightning Interceptor

1080.331
RED TOP AIR-TO-AIR MISSILE
DESCRIPTION:
Infra-red homing air-to-air weapon for use against sub- and super-sonic aircraft. All-altitude operation is possible against manoeuvring targets, and all-aspect attack capability is provided by the Red Top homing and guidance system.

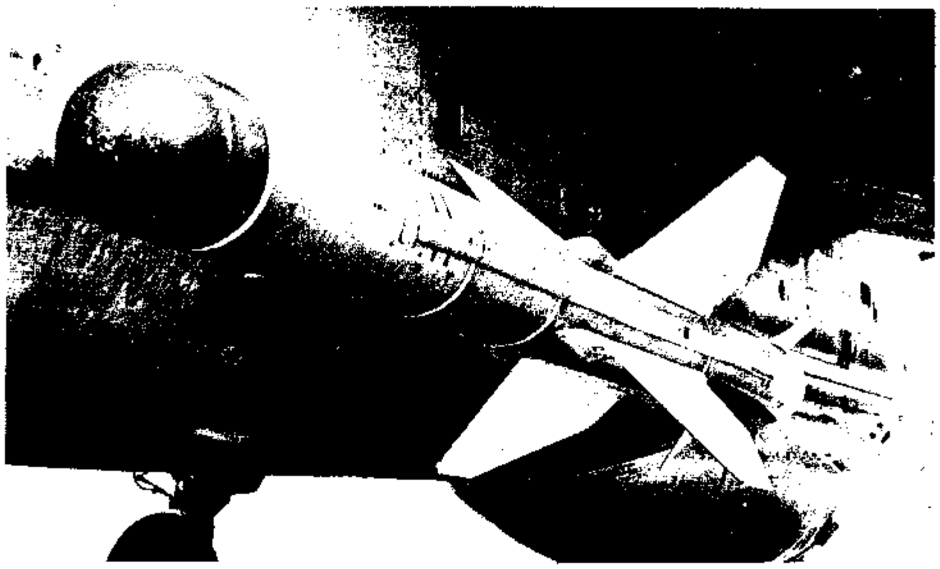
At one time referred to as Firestreak Mk IV, Red Top has a similar configuration and dimensions of the same order, but performance is considerably higher as a result of the application of advances in technology made since the start of Firestreak production.

Red Top retains the configuration of four fixed wings and four moving rear control surfaces, the design being further optimised to give operation over a very wide altitude and speed range. Wing and control surface planforms and sections differ from those of Firestreak, and match the unofficially quoted speed of Mach 3. The infra-red guidance system has been further developed to allow target interception from virtually any direction, and a hemispherical nose houses the I/R sensor.

Internally, the warhead (31 kg) has been moved forward, next to the fusing system and the control actuators have been located nearer to the surfaces they operate.

The power of the internal solid propellant booster rocket motor is also reported to be substantially greater than that of Firestreak, giving a range of at least 12 km

Missile dimensions are: length 3 27 m, diameter 22.2 cm, wing span 90.8 cm. Up to four missiles can be carried without significant detriment to aircraft performance.

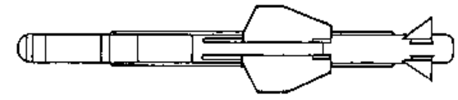


Red Top air-to-air missile on RAF Lightning interceptor

OPERATION:
Both complex and simple fire control systems can be employed for the operation of Red Top.

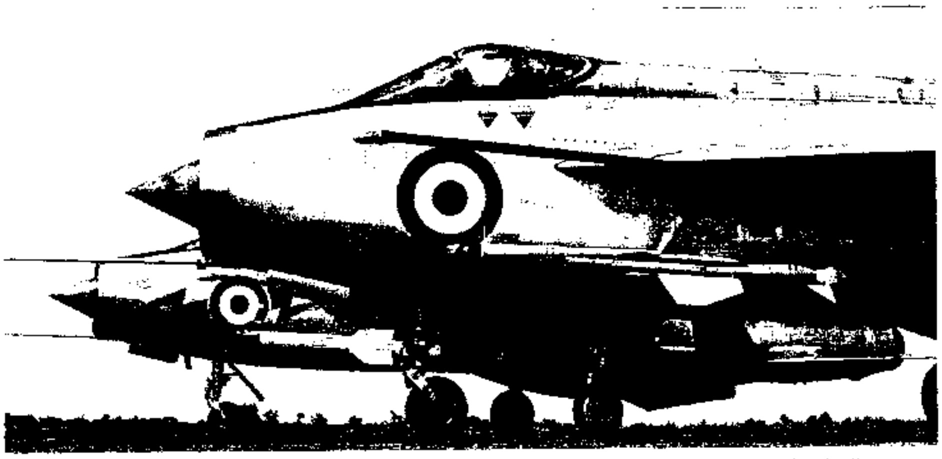
In simplified systems, the target may be acquired visually by the pilot and firing action taken upon receipt of a signal from the missile. By this method, the effectiveness of Red Top is maintained within a very compact weapon installation

The Red Top weapon system has been designed primarily as an integral part of the sophisticated United Kingdom defence system. However, the operational flexibility given by its all round attack capability allows easy adaptation to suit the requirements of any defence environment.
STATUS:
Red Top is in service with RAF Lightnings.
DEVELOPMENT:
Design studies were initiated in 1957 by



Red Top

Hawker Siddeley Dynamics in response to a UK Government requirement. Collaborating agencies included the Royal Aircraft Establishment, Royal Radar Establishment, and Royal Armament Research and Development Establishment.
MANUFACTURERS:
Hawker Siddeley Dynamics Ltd, Manor Road, Hatfield, Herts AL10 9LL, England

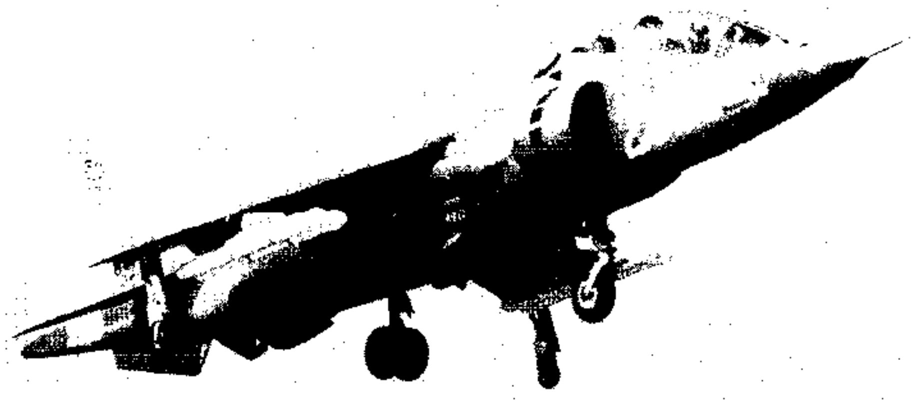


Lightning fighter aircraft carrying Red Top (nearest to camera) and Firestreak air-to-air missiles

1344.331
SRAAM SHORT RANGE AIR-TO-AIR MISSILE
DESCRIPTION:
SRAAM is a new type of close-combat air-to-air missile, designed to cope with the high accelerations encountered in dog-fight conditions. Its design is such that it can operate down to a very short minimum range, even with the target manoeuvring to its design limits. At the same time, the maximum range is comparable to that of existing air-to-air weapons.

Visually aimed, and guided by a passive infra-red homing system, its thrust vector control will enable it to out-manoeuvre all types of aircraft, including crossing targets at very short range. It has a wide aiming tolerance and its high explosive warhead will be detonated by proximity or contact fuses.

The simplicity of the fire control system enables the missile to be fitted to almost any aircraft. Two weapons in their tubes are mounted on a single launch beam which contains all the fire control system. On firing, the missile container tube nose cap opens and the missile leaves the launchers, the missile fins erecting automatically as it does so. The high manoeuvre capability of SRAAM is achieved by the use of a solid fuel propulsion system employing thrust vector control. Four spoiler tabs which can be moved in or out of the jet efflux are used to effect this control. Powered by a solid-propellant motor, SRAAM is 2.73 metres long and 0.168 metres in diameter.
STATUS:
A technology development programme, which includes air firings, is in progress to prove the SRAAM concept.
MANUFACTURER:
Hawker Siddeley Dynamics Ltd, Manor Road, Hatfield, Herts AL10 9LL, England



Harrier fitted with two twin tube SRAAM launchers

UK SPARROW AIR-TO-AIR MISSILE
DESCRIPTION:
The UK Sparrow is a new medium-range all-weather air-to-air missile for the Royal Air Force. It is based on the Raytheon Sparrow missile and has the same general configuration and dimensions. It is a semi-active radar guided missile capable of attacking both sub-sonic and supersonic targets from very low to high altitudes and has an all-round attack capability. It employs a new advanced guidance system developed by Marconi Space and Defence Systems at Stanmore, Middlesex and a new advanced fuse system developed by EMI Electronics Ltd, at Hayes, Middlesex. The auto-pilot and power systems are being updated by Hawker Siddeley Dynamics Ltd, to include solid-state electronics and thermal batteries in place of the existing electronics and power systems to improve reliability. The missile structure will be built by Hawker Siddeley Dynamics who will also carry out assembly and test.
STATUS:
Project definition was completed in 1973 with the development programme following immediately. The development and initial production programme has been agreed with the Ministry of Defence and full development is proceeding.
MANUFACTURERS:
Hawker Siddeley Dynamics Ltd – Prime contractor
Marconi Space and Defence Systems Ltd – Homing head
EMI Electronics Ltd – Fuse
Raytheon Company – Main sub contractor

RAF Phantoms carrying Sparrow air-to-air missiles

THE UNITED STATES OF AMERICA

1302.331
AGILE (AIM-95) AIR-TO-AIR MISSILE

DESCRIPTION

Agile (AIM-95) is being developed by the US Navy as a thrust-vector controlled missile featuring better manoeuvrability and shorter minimum range than Sidewinder, which because of its configuration has inherent limitations in both of these aspects. Originally linked with the F-14 and F-15 aircraft programme, Agile is now seen as a weapon suitable for deployment on most fighter and strike aircraft, the former for close-in engagements and as a self defence weapon for aircraft of the latter category.

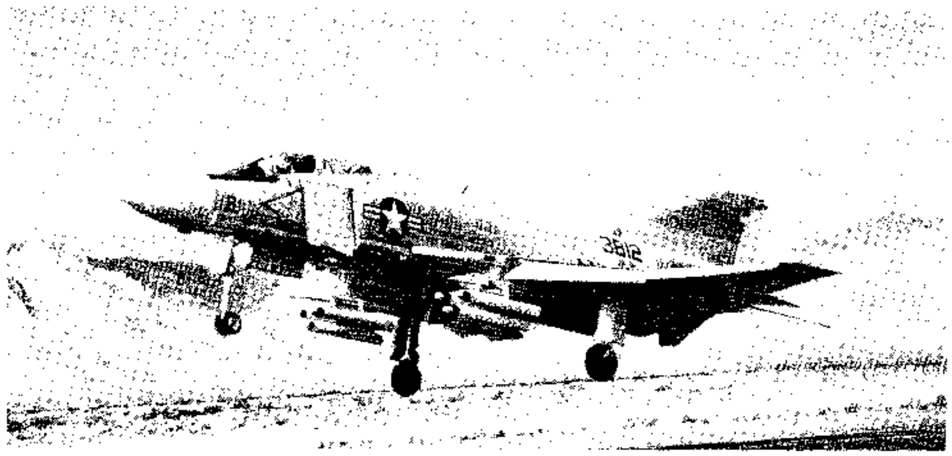
Hughes Aircraft is engaged on the development of the guidance system and the propulsion system is the responsibility of the Thiokol Corporation. The US Navy requirement calls for a missile capable of sharp, high-g turns and with a greater seeker tracking angle than current weapons, with the objective of giving USN aircraft a first-shot capability in combat. The main line of development has been based on the use of an infra-red homing head, but tests have been made of an electro-optical head and there are plans for an RF anti-radiation homing system so that Agile could be used in a defence suppression role. A new warhead which uses annular blast fragmentation is under development by the Navy.

The configuration of Agile is shown in the accompanying illustrations. The rotating assembly of eight folding fins at the rear are for stabilisation only, missile steering being effected by an hydraulically actuated gimballed nozzle for the Thiokol solid propellant motor which is housed forward in the missile body.

Cannister/launchers will be used, and either single or multiple attachments are under study as shown in the photographs. In addition to the thrust-vector controlled version of Agile, the USN has also developed a winged version which is regarded as a back-up to the main line of development and as an extra technology study facility.

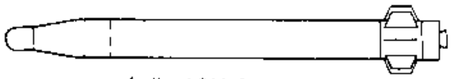
DEVELOPMENT

Development of Agile began in 1968 under the management of the US Naval Weapons Centre, China Lake. Hughes Aircraft was selected to develop the guidance element in 1973, with Thiokol as the propulsion contractor. By early 1974 the USN was engaged in extensive analysis of data derived from a number of ground firings of Agile and from simulator tests in the course of which more than 1.5 million simulated firings of Agile under combat conditions were made and recorded. This activity has been complemented by a number of airborne flight trials of Agile models and seekers. A programme review by the DoD in the summer of 1974 was arranged to determine the direction of subsequent development and procurement plans.



Agile missile mockups on Phantom aircraft for aerodynamic tests

Single Agile launchers on A-7 aircraft



Agile (AGM-95)

STATUS

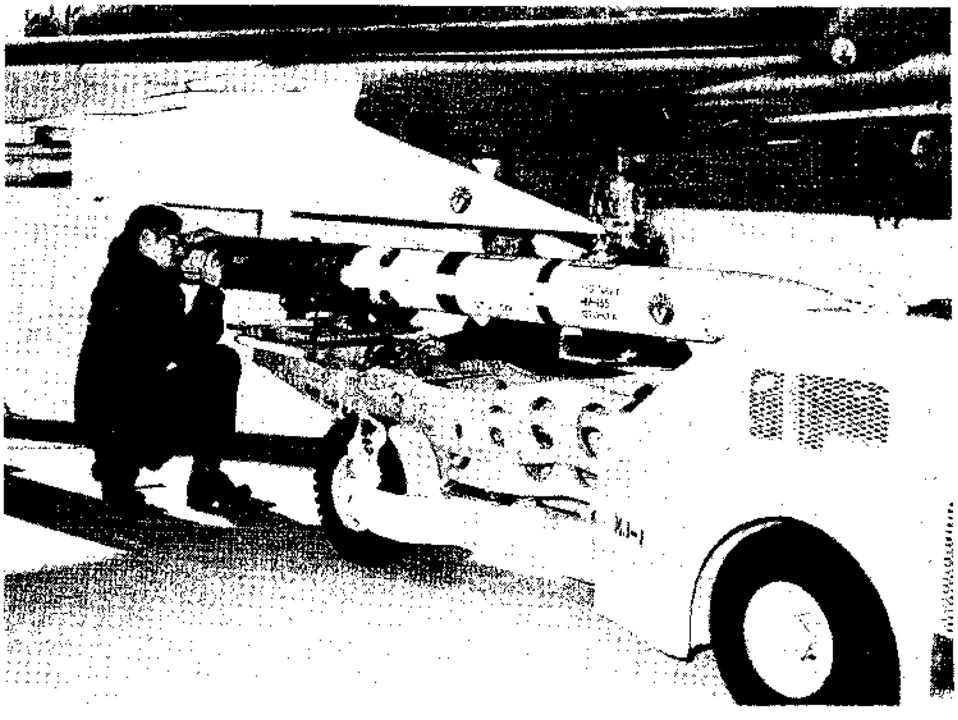
Although Agile hardware prototypes had been virtually completed by May 1974, the decision to enter engineering development was delayed until feasibility models can be flight tested and the requirement better defined. Agile RDT&E funding allocation in Fiscal Years 1973 and 1974 was $16.5-million and $18.0-million, respectively, and $20.0-million was sought for FY 1975.

1657.331
BRAZO AIR-TO-AIR ANTI-RADIATION MISSILE

DESCRIPTION:

The designation Brazo (Spanish for 'arm') has been given to a US Navy project for the development of an air-to-air defence missile that will home on to the radars of attacking aircraft such as the Soviet Foxbat high-speed, high-altitude fighter. Since the programme was made public in mid-1972, the USAF has joined in and will be responsible for test and evaluation.

The US Naval Electronics Centre is designing a passive broad-band anti-radiation homing head for the missile which is expected to be based on the Sparrow. Hughes Aircraft has been made responsible for the integration of the new heads with a quantity of Sparrow missiles which will be used for test and demonstration flights during 1973 and 1974. A BQM-34 drone was intercepted in the first air launch from an F-4D in April 1974. The USAF has given its part in the project the name of Pave Arm. The first free flight of an unarmed Brazo test vehicle was made from an F-4 fighter aircraft on April 16, 1974 at Holloman AFB. The target was a BQM-34 drone.



A test Brazo missile being checked out before the first air firing from an F-4D at Holloman Air Force New Mexico

FALCON (AIM-4A) AIR-TO-AIR MISSILE

DESCRIPTION:

Lightweight air-to-air missile equipped with a semi-active radar homing head operating in conjunction with a target illuminating radar carried by the launching aircraft. Powered by solid fuel rocket motor. High explosive warhead. Principal characteristics are: length 198 cm, diameter 16.25 cm, wing span 50.8 cm, weight about 54.4 kg.

DEVELOPMENT:

Falcon was developed jointly by Hughes and the USAF, work starting on the project in 1947. An experimental model was produced two years later. First production models appeared in 1954. The Falcon was introduced as the GAR-1 and about 4,000 were built before an improved version appeared as the GAR-1D (now AIM-4A). Over 12,000 of this model were produced.

STATUS:

Numerous early USAF interceptor aircraft were armed with AIM-4A Falcons, and among later types of aircraft was the F-102A.

MANUFACTURER:

Hughes Aircraft Company, Culver City, California 90230, USA.

AIM-4A (formerly GAP-1D) air-to-air Falcon Missile. Semi-active radar homing is used in this version (USAF Official Photograph)

1084.331

FALCON (AIM-4C) AIR-TO-AIR MISSILE

DESCRIPTION:

Lightweight air-to-air missile, similar to the AIM-4A Falcon but equipped with infra-red guidance system instead of semi-active radar homing. Powered by solid fuel rocket motor. High explosive warhead. Principal characteristics are: length 198 cm, diameter 16.25 cm, wing span 50.8 cm, weight about 54.4 kg.

DEVELOPMENT:

The AIM-4C was developed by Hughes as a successor to the GAR-1 and GAR-1D (AIM-4A). Designation at the time of development was GAR-2. This version of Falcon was introduced in 1956, and after some 16,000 units had been produced an improved model, GAR-2A, was produced. This featured improved I/R equipment to give a wider operational environment. Over 10,000 examples of this model were built.

STATUS:

Aircraft that have been equipped with AIM-4C Falcons include the F-101B, F-102A.

MANUFACTURER:

Hughes Aircraft Company, Culver City, California 90230, USA

AIM-4C (formerly GAR-2A) air-to-air Falcon missile. Infra-red homing system is used in this version (USAF Official photograph)

1085.331

FALCON (AIM-4D) AIR-TO-AIR MISSILE

DESCRIPTION:

Lightweight air-to-air missile similar in size and configuration to the AIM-4C but equipped with the improved infra-red homing head of the larger AIM-4G Super Falcon. This gives better performance against high-speed manoeuvring targets and confers all-aspect attack capability. Principal characteristics are: length 198 cm, diameter 16.25 cm, wing span 50.8 cm, weight about 60 kg. Solid fuel motor. High explosive warhead. Speed Mach 4.

DEVELOPMENT:

Chronologically, development of the AIM-4D took place after that of other members of the Falcon series, such as AIM-4E, F, and G (which see) and its former designation was GAR-2B. As air defence missiles, earlier Falcon versions were designed for the interception of bomber aircraft. AIM-4D development was undertaken to improve performance sufficiently for the engagement of enemy fighter aircraft. This was undertaken under a joint USAF/Hughes programme.

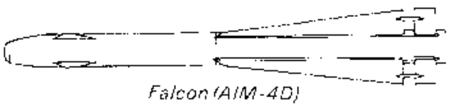
STATUS:

AIM-4D has been ordered by USAF Tactical Air Command, and aircraft to be fitted include the F-4. Thousands of AIM-4A and C Falcons have been converted to AIM-4D standard.

MANUFACTURER:

Hughes Aircraft Company, Culver City, California 90230, USA.

AIM-4D Falcon air-to-air missile being loaded onto wing pylon of an F-4 Phantom. This version of the Falcon incorporates the main body structure of the AIM-4A & C versions with the later infra-red homing system of the AIM-4G



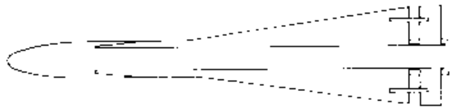
Falcon (AIM-4D)

1086.331

SUPER FALCON (AIM-4E & AIM-4F) AIR TO-AIR MISSILE

DESCRIPTION:

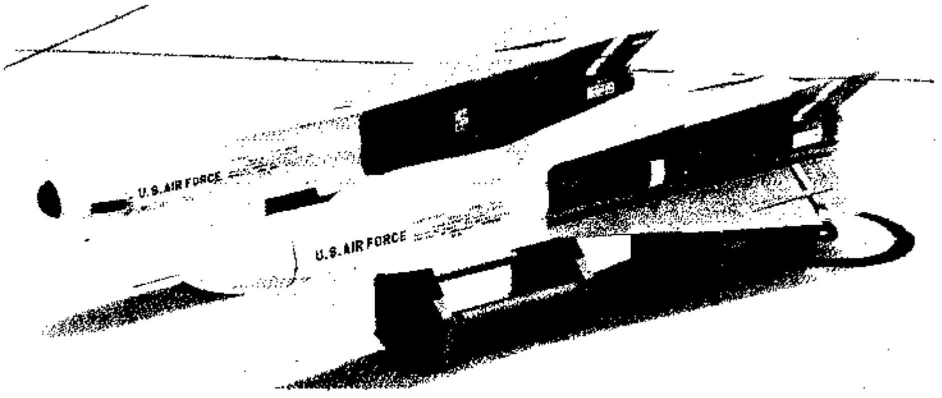
These two missiles represent an interim stage in the development of the Falcon series, coming between the AIM 4A and C and the AIM-26 models. In general configuration the AIM-4E more closely resembles the AIM-4F. This was equipped with an improved radar guidance system providing increased accuracy and greater resistance to ECM. A new solid fuel, two-level thrust rocket motor was installed to provide a high launching thrust followed by a lower level thrust to sustain missile velocity. An external feature is a 10 cm metal probe attached to the nose cone to improve missile aerodynamics.



Falcon (AIM-4E)

Guidance is by semi-active radar homing as in the AIM-4A. The AIM-4E was powered by a longer burning solid fuel rocket motor to provide longer range, a higher launching speed, and a higher combat ceiling than earlier models. A more powerful high explosive warhead was also fitted. Only about 300 models of this version were produced before being succeeded by the later variants, the AIM-4F and AIM-4G. The wings are extended forward by fillets, and weight and dimensions are slightly increased to: length 218.4 cm, diameter 16.5 cm, wing span 60.9 cm, weight about 63.5 kg, in the case of the AIM-4E, and – length 218.4 cm, diameter 16.7 cm, wing span 60.9 cm, weight 68 kg, for the AIM-4F. Speed of the AIM-4F is Mach 3.

DEVELOPMENT:
The AIM-4E was originally developed as the GAR-3 and was introduced in 1958. It was succeeded two years later, after 300 units had been produced, by the AIM-4F (formerly GAR-3A).

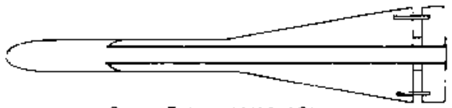


Hughes Super Falcon air-to-air missiles. The semi-active radar guided AIM-4F version is seen front, with the infra-red homing AIM-4G version behind it

STATUS:
Aircraft equipped include the F-106 Delta Dart interceptor.

MANUFACTURER:
Hughes Aircraft Company, Culver City, California 90230, USA.

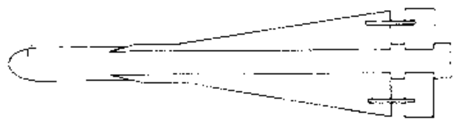
1087.331
SUPER FALCON (AIM-4G) AIR-TO-AIR MISSILE
DESCRIPTION:
The AIM-4G Super Falcon is the infra-red seeking counterpart of the AIM-4F missile. It is equipped with an I/R detector system which enables it to lock-on to smaller targets at greater ranges than earlier Hughes infra-red missiles. The same seeker is used in the AIM-4D Falcon. Compared with the AIM-4F Super Falcon, the AIM-4G is shorter (105.7 cm) and weighs slightly less (65.7 kg). A high-explosive warhead is fitted. Unofficial weight is 18 kg, and speed Mach 3.
DEVELOPMENT:
The AIM-4G was developed under the original designation GAR-4A, in parallel with the GAR-3A (AIM-4F). It was introduced in 1959/60.



Super Falcon (AIM-4G)

MANUFACTURER:
Hughes Aircraft Company, Culver City, California 90230, USA.

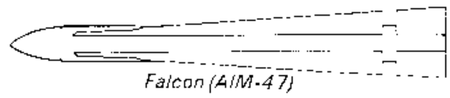
1089.331
FALCON (XAIM-26A & AIM-26B) AIR-TO-AIR MISSILE
DESCRIPTION:
The AIM-26 versions of Falcon were the result of a major programme to improve the capability of this successful series of missiles. An important consideration was the desire to achieve reliable head-on attack capability and guidance; for this reason radar homing guidance was chosen instead of infra-red; advantages of radar in this context being all-weather capability and longer acquisition range. The far higher closing speed assists in such types of engagement. There is also a possibility of the missile homing onto a forward looking radar in the target aircraft if such an equipment is fitted, and provided the operating frequencies and bandwidths of target and missile radar units are compatible.
To offset the rather lower accuracy of radar guidance compared with I/R, a much heavier warhead was called for to increase range of lethality due to blast.
An experimental series of missiles XAIM-26A (formerly XGAR-11) was introduced in the Spring of 1960. These models, while bearing a family resemblance to earlier Falcons, presented a very much bulkier appearance and were in fact much heavier – about 90 kg. Length was 213.4 cm and maximum diameter 27.9 cm. Wing span remained about 60 cm.
Extra weight was accounted for by a larger motor and heavier warhead, the former probably being required more for increased range rather than speed. An active proximity fuse, suitable for 'near-miss' kill capability, was also fitted and this



Falcon (AIM-26A)

is believed to have been based on radar. Four fuse aerials are located almost flush with the missile body, ahead of the wings. The warhead was essentially the same as that of the nuclear Genie missile (which see).
The XAIM-26A was followed by the AIM-26B (formerly GAR-11A), a conventional explosive warhead version of the AIM-26A.
MANUFACTURER:
Hughes Aircraft Company, Culver City, California 90230, USA.

1090.331
FALCON (AIM-47A) AIR-TO-AIR MISSILE
DESCRIPTION:
This is the largest of the Falcon series of air-to-air missiles and is about twice the size and weight of the AIM-4 series of weapons. Estimated dimensions are: length 320 cm, diameter 33.5 cm, wing span 83.8 cm, weight 363 kg. A solid-propellant motor is used and the AIM-47A has been credited with a range of 100 nautical miles and a speed of Mach 6.
Guidance is semi-active radar homing with the Hughes AN/ASG-18 fire control system radar acting as target illuminator. It is reported that either nuclear or conventional payloads can be carried.
DEVELOPMENT:
AIM-47A was originally developed under the



Falcon (AIM-47)

designation GAR-9 for the USAF as part of the YF-12A Mach 3 defence interceptor programme.
MANUFACTURER:
Hughes Aircraft Company, Culver City, California 90230, USA.

1091.331
GENIE (AIR-2A) AIR-TO-AIR MISSILE
DESCRIPTION
Air-to-air unguided missile carrying a nuclear warhead. A Thiokol solid-propellant rocket motor is used to give the Genie a range of 6 miles (9.6 km) and a speed of Mach 3. Operating ceiling is over 15,0.. m. Principal dimensions are: length 274 cm, diameter 43 cm, weight about 370 kg.
OPERATION:
Launching of the Genie is normally automatic under the control of a Hughes fire control system (probably the MG-10) which is reported to be responsible also for detonation of the warhead when the launch aircraft is at a safe distance. Arming of the nuclear warhead has to be carried out by pilot action prior to launch.
Genie is used with existing air defence systems as follows:
Radar detection of an approaching unidentified aircraft is relayed to the Air Defence Direction Centre. The ADDC plots the potential target and alerts the appropriate Air Defence Command base. An interceptor, armed with Genie rockets, is despatched and guided toward the incoming aircraft or group of aircraft.
Upon reaching the target's area, the aircraft's fire control system locks on the target. If the target is identified as hostile, the Genie is automatically launched by the fire control system, and the aircraft swings away from the area. Approaching at supersonic speed toward the enemy craft, the missile detonates with a lethal blast.
DEVELOPMENT:
Development began in 1954 and was carried out under the former designation MB-1. The first successful tests were carried out from F-89D aircraft in 1956, and later the same year from YF-

Genie (AIR-2A)

102 aircraft. A further version of Genie, AIR-2B was under development as the Super Genie, which according to unconfirmed reports would incorporate a guidance capability. This work is now suspended. The Genie development programme, prior to introduction of the missile into service, was also known as Ding Dong and High Card.
STATUS:
Genie became operational in January 1957 with USAF Air Defence Command and is operational with F-101 and F-106 aircraft. Production ceased in 1962 but is stated to extend into

thousands
MANUFACTURERS:
McDonnell-Douglas Astronautics Company, Huntington Beach, California 92647, USA.
ADDITIONAL EQUIPMENT
A practice round, for training purposes and without nuclear payload, is in service under the designation ATR-2A.

1099.331
PHOENIX (AIM-54A) AIR-TO-AIR MISSILE
DESCRIPTION:
Long-range, high performance air-to-air weapon, originally developed for deployment with US Navy F111B aircraft for fleet area defence purposes, but now in use with USN F-14 Tomcat interceptor aircraft. Officially issued characteristics include: length 396 cm, diameter 38 cm, wing span 91.4 cm, weight 380 kg. Radar homing. Mk 47 Mod 0 solid-propellant rocket motor by North American Rockwell Rocketdyne Division. Estimated range is between 60 and 90 nautical miles (110-165 km).
The complete Phoenix weapon system as developed for the F-111B (since cancelled) comprised the Hughes AWG-9 fire control and armament system – also referred to as AMCS (Airborne Missile Control System) – and interface sub-systems to tie in Phoenix-carrying aircraft with other fleet units. Digital computers are incorporated in both of the aircraft-fitted elements of the Phoenix system.
OPERATION:
During the cruise phase of missile flight, Phoenix guidance is by semi-active radar homing, the AWG-9 serving as target illuminator. Terminal guidance, reportedly within 16 km of the target, is by active radar.
The Phoenix missile incorporates a small doppler radar transmitter which is switched on to provide target illumination during the terminal guidance phase.
The complementary I/R target tracker can be used for the direction of missiles at shorter ranges, the cruise phase of flight being unguided until the active radar homer takes over for the terminal phase. In this mode the AWG-9 radar need not be used.
The ability of the AWG-9 to launch up to six missiles simultaneously against six separate targets implies that there must be a system of coding the illuminating radar transmissions during the cruise phase of missile flight to ensure that each missile pursues its designated target.
Proximity and I/R fusing methods are understood to be employed for the detonation of Phoenix missiles.
DEVELOPMENT:
The Phoenix concept was initiated in 1960 and Hughes was selected as prime contractor by the US Navy in 1962. Flight testing began in 1965, and the first successful intercept was in September 1966. The simultaneous attack capability was demonstrated in March 1969 when two drones were successfully engaged from an F-111B aircraft.
Phoenix procurement was initiated during Fiscal Year 1971. In December 1970 the Hughes Aircraft Corporation was awarded a $29,851,689 contract modification for pre-production testing and incremental funding for the AWG-9 AMCS. The US Navy requested a total of $108.8 million for Fiscal Year 1973, $98.4 for procurement, $5.3 for spares, and $5.1 for development. F-14 flight trials started in April 1972, and in December of that year four jet drone targets were successfully engaged by four Phoenix missiles launched and directed by the AWG-9 system of an F-14 Tomcat.
STATUS
The first Phoenix units were operational by Spring 1974, and procurement for Fiscal Years 1973/4/5 amounts to 180, 240, and 340, respectively. The corresponding funding for these was $89.3m, $92.5m and $94.7m.

SEEK BAT (XAIM-97A) AIR-TO-AIR MISSILE

DESCRIPTION:

Seek Bat is the result of a joint USAF/General Dynamics programme to evolve a high-altitude, long-range air-to-air missile to counter the MiG-25 Foxbat interceptor aircraft, and based on the existing AGM-78 Standard ARM missile airframe. A larger propulsion unit is employed and the missile guidance system is stated to acquire and lock-on to the target before release from the launch aircraft. Infra-red homing is used to direct the Seek Bat on a pursuit course by tracking the Foxbat's exhaust trail. Interceptions at heights up to 80,000 ft (24,300 m) are intended.

STATUS:

The XAIM-97A is in development, and tests against drones started in late 1972/early 1973.

1103.331

SIDEWINDER 1A (AIM-9B) AIR-TO-AIR MISSILE

DESCRIPTION:

Short/medium-range air-to-air infra-red homing missile, for pursuit engagements. Principal characteristics are length 284 cm, diameter 12.7 cm, fin span 60.9 cm, weight 75 kg, speed Mach 2, ceiling over 15,000 m, sea-level range 1,100 m. A Rocketdyne solid-propellant motor is used and a high explosive warhead is fitted. Other features are simple design and low cost.

The AIM-9B version is in the inventory of numerous air forces and a European consortium headed by Bodenseewerk Gerätetechnik GmbH undertook licence manufacture of Sidewinders for NATO countries.

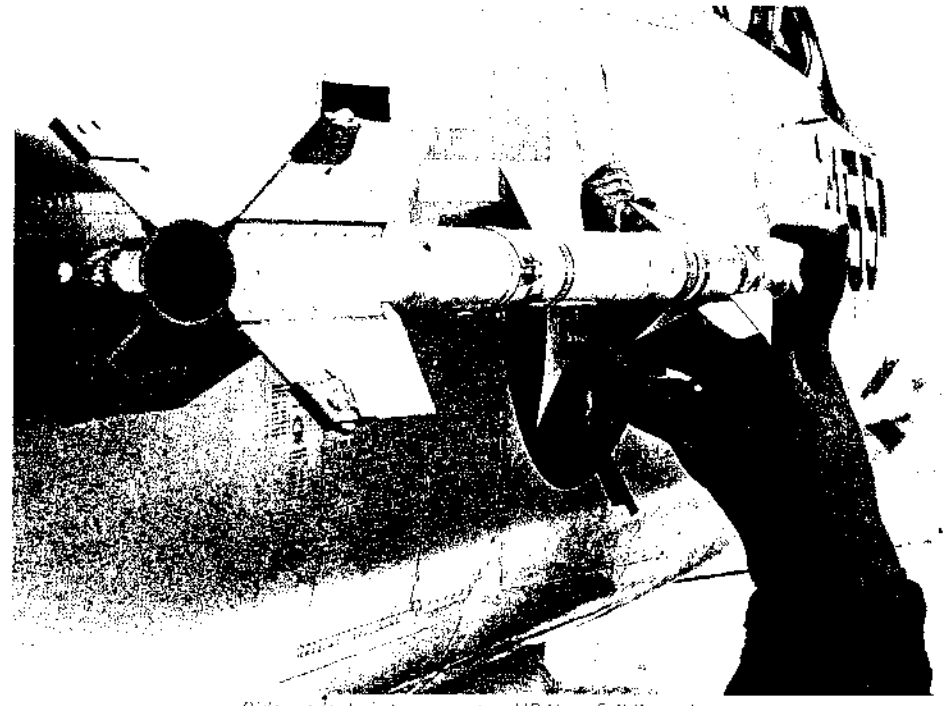
Bodenseewerk Gerätetechnik (formerly Fluggerätewerk Bodensee GmbH) was prime contractor for European production under licence of the American Sidewinder 1A (AIM-9B) air-to-air missile.

Bodenseewerk Gerätetechnik has developed an improved guidance and control unit for the Sidewinder missile, known by the designation FGW Mod 2. This is intended to increase the effectiveness of the missile against manoeuvring targets, against targets moving in front of sunlit backgrounds and in bad weather conditions.

The improvement to the infra-red system is achieved by using cooled detectors to increase sensitivity and reduce the effects of background clutter. The tracking rate against manoeuvring targets is increased by using more modern electronic components.

The German Air Force and operators in various other NATO countries modified their stocks of Sidewinder guidance and control units to the FWG Mod 2 standard. Bodenseewerk was also awarded a follow-on contract for the supply of complete Sidewinder missiles equipped with FWG Mod 2 guidance and control units. This work has been completed.

AIM-9B entered operational service in July 1956 and when US production ended in 1962, over 60,000 missiles had been procured for use by US and Allied services. At least 9,000 have been produced by the Bodenseewerk group. Most American AIM-9Bs have been the subject of a programme of conversion to AIM-9E standard.



Sidewinder being prepared on US Navy F-8 Crusader

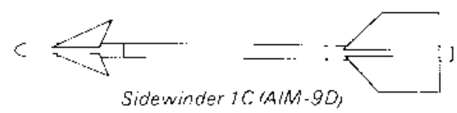
AIM-9B Sidewinder air-to-air missile mounted on wing of F-104A Starfighter

1104.331
SIDEWINDER 1C (AIM-9C and AIM-9D) AIR-TO-AIR MISSILE

DESCRIPTION:
Short/medium range air-to-air missile. The AIM-9C uses semi-active radar homing by Motorola, and the AIM-9D version employs infra-red guidance produced by Raytheon and Philco-Ford. In general appearance these models of Sidewinder are very similar to the earlier AIM-9B but a higher thrust motor is used which increases range to 18 km. Weight is 84 kg.

The radar homing head used in the AIM-9C can be used either in conjunction with the target illu-



Sidewinder 1C (AIM-9D)

minating radar of the launch aircraft or it can home on to radiation from ECM signals transmitted from the target aircraft. Designation of this guidance system is the Mk 12 Mod 3 guidance and control group. The infra-red system used in the AIM-9D is designated Mk 18 Mod 1.

STATUS:
The two Sidewinder 1C versions (AIM-9C and D) entered service in 1965, and it is understood that the bulk of production has been against US Navy requirements. The AIM-9D is reported to be in the UK inventory, and all future US Navy procurement is likely to be for this version of Sidewinder.

MANUFACTURERS
Raytheon Company, Missile Systems Division, Bedford, Massachusetts 01730, USA.
Philco-Ford Corporation, Communications and Electronics Division, Willow Grove, Philadelphia USA.
Motorola Inc. Government Electronics Division, 8201 East McDowell Rd, Scottsdale, Arizona 85252, USA.

1105.331
SIDEWINDER (AIM-9E) AIR-TO-AIR MISSILE

DESCRIPTION:
This is a modified version of the AIM-9B missile and incorporates an improved infra-red homing head and other modifications to increase low altitude performance. The AIM-9E is also known by the designation of Sidewinder LAP as a result of this characteristic. The modification programme was initiated by the USAF and it is understood that all AIM-9E missiles are the result of a major programme to update stored AIM-9B models. Production of AIM-9Es ceased in 1969, but Philco-Ford was awarded a $29.8 million USAF contract in September 1970 for a technical improvement programme to bring AIM-9B Sidewinders up to AIM-9J standard.

MANUFACTURER:
Aeronutronic Division, Philco-Ford Corporation, Ford Road, Newport Beach, California 92663, USA.

1308.331
SIDEWINDER (AIM-9G/H/J) AIR-TO-AIR MISSILE

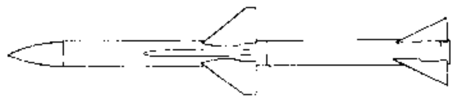
DESCRIPTION:
The AIM-9G Sidewinder is similar to earlier versions except for the addition of a vacuum tube and the Sidewinder Expanded Acquisition Mode (SEAM) system, which is said to have provided increased lead acquisition capability. The AIM-9H version incorporates SEAM plus solid-state electronics. It became operational with the US Navy in August 1970. In January 1972 Philco-Ford was awarded a $4.3 million USN contract for the production of improved AIM-9H guidance and control systems.

The AIM-9J is another improved version of the AIM-9B, and for which Philco-Ford is responsible. This version uses the same seeker as the AIM-9E but has canards of modified design and a high-performance servo system. In March 1972 it was revealed that a number of Sidewinders had been modified for an air-to-ground role, using a laser-seeker guidance system. Such missiles have been given the designation Focus (AGM-87A). No details of production contracts have been announced and the weapon is believed to be under test by the US Navy. AIM-9G procurement funding requested for 1974 was $16.8 million for the USAF and USN. Another improved version, sometimes called Super Sidewinder and designated AIM-9L, is in development for dog-fight missions and as a possible alternative for Agile (Entry No. **1302.331**).

1106.331
SPARROW III (AIM-7E/F) AIR-TO-AIR MISSILE

DESCRIPTION:
The Sparrow missile is one of the most widely-used and successful US weapons and it is currently being put to numerous applications in addition to its original role of air-to-air combat. The present production version is the AIM-7E which is 3.65 metres long, 20 cm in diameter, with a wingspan of 1.0 metre and tail fins of 82 cm span. Weight is 200 kg and a 30 kg high-explosive warhead is carried. Semi-active CW radar guidance is employed, with proximity or contact fusing of the charge. Range is about 25 km. An AIM-7E-2 version is reported to be capable of greater manoeuvrability to suit it for close-in dog-fight engagements, which also differs from the AIM-7E in having plug-in fins that do not require tools for insertion or removal.

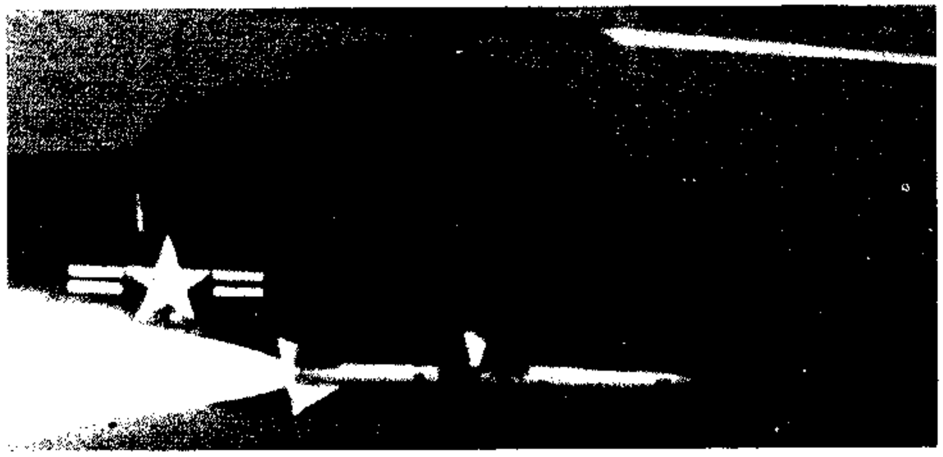
A version of the AIM-7E Sparrow as used in the NATO Seasparrow surface-to-air system bears the designation RIM-7H and differs in having folding fins to reduce the size and weight of the deck launcher/containers. The US Navy Basic Point Defence Missile System uses a version based on the AIM-7D Sparrow.



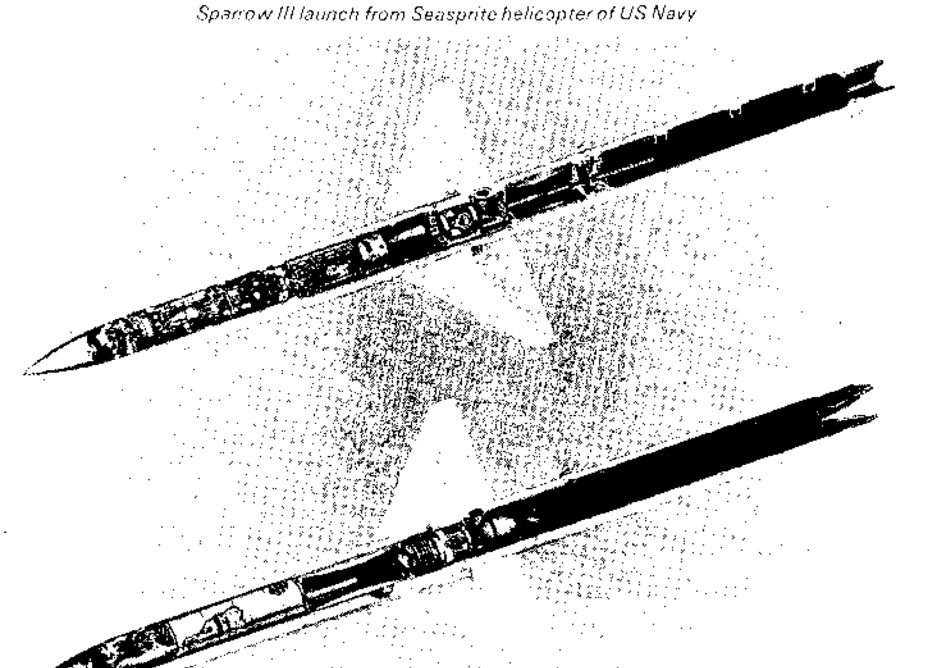
Sparrow (AIM-7)

The latest air-to-air version is the AIM-7F. This has all solid-state electronics for its improved semi-active radar guidance system and a larger solid-propellant rocket motor providing increased range. The weight is somewhat greater than that of the AIM-7E. The Sparrow missile is also forming the basic vehicle for the USN/USAF Brazo/Pave Arm weapon programme (Entry No. **1657.331**) in which application a laser-seeking homing head will be fitted.

In mid-1972 the British Government announced a programme under which EMI would develop a new fuse and Marconi Space and Defence Systems a new homing head suitable for fitting to Sparrow III missiles, and Hawker Siddeley Dyna-



Sparrow III launch from Seasprite helicopter of US Navy



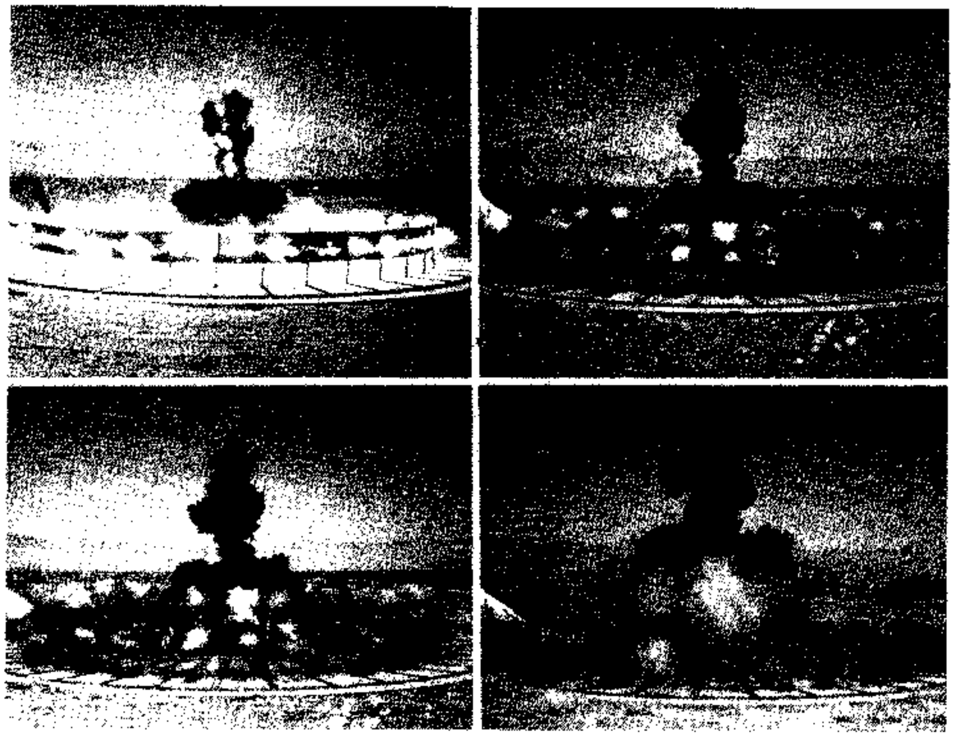
Cutaway drawings of AIM-7E and AIM-7F versions of Sparrow, showing improved electronics and larger motor mics was entrusted with integration. This led to a programme to develop a UK version of Sparrow (1774.331), and Hawker Siddeley was given access to Raytheon engineering information and the US company was granted licence rights for the Marconi head.

STATUS:

Sparrow III is in widespread use by American air forces and those of other NATO nations. Procurement in Fiscal Years 1973/4/5 was for 150, 175, and 600 missiles, respectively, for both USAF and USN requirements.

MANUFACTURER:

Raytheon Company, Missile Systems Division, Bedford, Mass 01730, USA.



Sequence of Sparrow warhead ground test

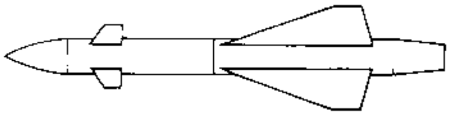
THE UNION OF SOVIET SOCIALIST REPUBLICS

1143.331
ALKALI AIR-TO-AIR MISSILE

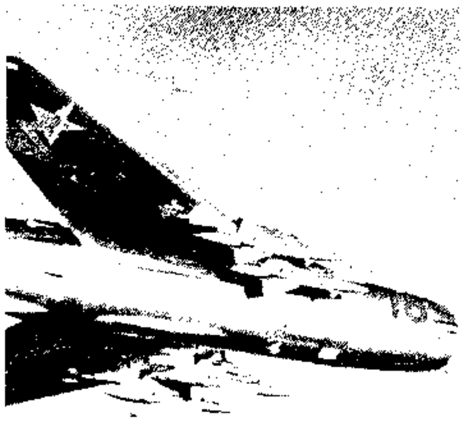
DESCRIPTION:

Alkali is the NATO code-name assigned to the Soviet air-to-air missile normally deployed on the MiG-19 interceptor, and also reported as having been carried by the MiG-17, and the Su-9. Estimated length is 188 cm, diameter 18 cm. Span of the rear fins about 58 cm, and of the forward set 32 cm. Use of a solid-fuel motor is assumed. Range is probably not more than 6-8 km, and speed between Mach 1 and 2.

Alkali guidance is generally believed to be radar based in view of the deployment of this missile on 'all-weather' interceptors, in which case it is probably of the passive homing type, with the launch aircraft fire control radar providing target illumination.



Alkali

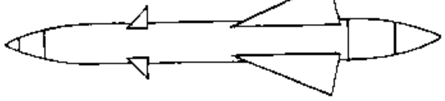


Alkali air-to-air missile

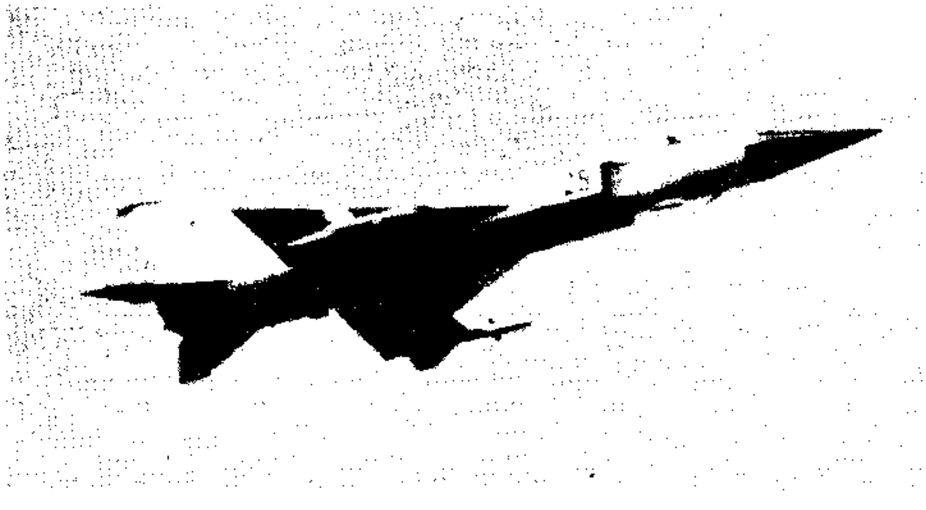
1144.331
ANAB AIR-TO-AIR MISSILE

DESCRIPTION:

Anab is the NATO code-name assigned to the Soviet air-to-air missile first seen carried by the Yak-28 (Firebar) in 1961. It has subsequently been seen on the Su-9 (Fishpot) interceptor, and is known to have been adopted as a standard weapon by the Soviet forces.



Anab



SU-11 aircraft with Anab missiles

The existence of both radar and infra-red homing versions have been reported. Length of both versions is estimated at approximately 360 cm, diameter 28 cm, wing span 130 cm. Anab has a cylindrical body with a large cruciform wing assembly at the rear of the missile, and a set of four in-line fins ahead of the wings, and about one-quarter of the missile length from the nose end.

Solid fuel propulsion is assumed, and probable range is 8-10 km.

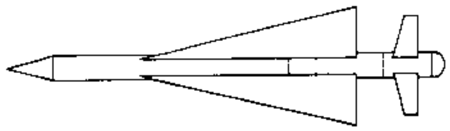
1145.331
ASH (AA-5) AIR-TO-AIR MISSILE

DESCRIPTION:

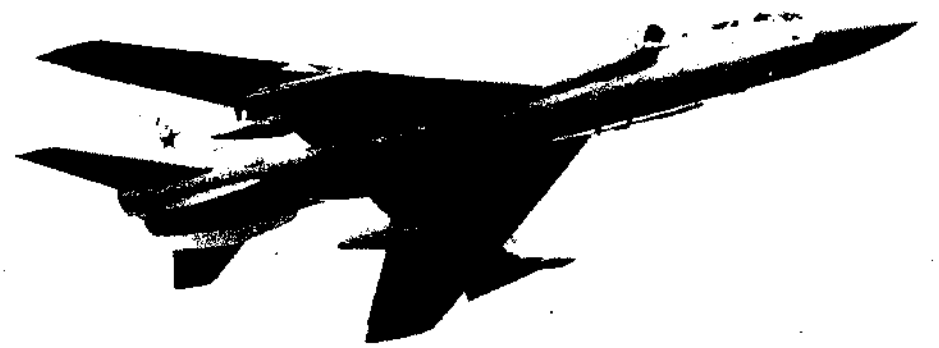
Ash is the NATO code name assigned to large missiles carried beneath the wings of Soviet Tupolev "Fiddler" long-range interceptor aircraft. Four such missiles, which are assumed by western observers to be air to air weapons, can be carried by each aircraft. Both radar guided and infra-red homing versions are in use, two radar homing missiles generally being carried on the wing outer pylons and two infra-red homing missiles on the inner pylons of the Fidd.er interceptor.

Estimated dimensions are: length 330 cm, wing span 130 cm, diameter 30 cm. Cruciform wing and tail surfaces, in-line, are fitted, the former having a sharply swept delta planform. The tail fins have little sweep on either leading or trailing edges and are mounted close behind the wing trailing edges.

The size of the missiles, parent aircraft, and the large nose radome of the latter, suggests that they are intended for long-range interception.



Ash (radar version)



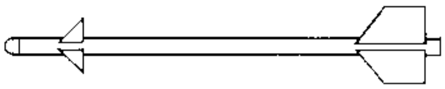
Ash air-to-air missile carried by Fiddler long range intercepter

Radar and infra-red guided Ash air-to-air missiles on Soviet Fiddler aircraft (Novosti Photograph)

1146.331
ATOLL AIR-TO-AIR MISSILE
DESCRIPTION:

Atoll is the NATO code-name assigned to a Soviet air-to-air missile, believed to bear the USSR designation SB06.

This missile closely resembles the American AIM-9B, infra-homing Sidewinder and is of similar dimensions and (estimated) weight. Atoll dimensions are: length 280 cm, diameter 12 cm, forward control surfaces span 45 cm, tail plane



Atoll

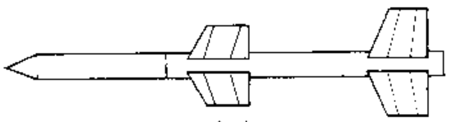
span 53 cm. Solid-propellant and conventional high explosive warhead are assumed.

Diametrically opposed pairs of the forward control surfaces are linked and work in unison for missile steering. The rear surfaces incorporate small tabs in which are inserted gyroscopic wheels driven by the airstream. It has been deduced that these are locked until after missile launch, and that their subsequent purpose is to provide additional stabilisation and/or a measure of control augmentation for missile steering.

Atoll is widely deployed with MiG-21 (Fishbed) interceptors of the Soviet home forces and on export versions of this aircraft. Known foreign users include Egypt and India. The latter country, which has over 50 MiG-21s, is setting up facilities for Atoll production under licence.

1246.331
AWL AIR-TO-AIR MISSILE
DESCRIPTION:

Very little is known of the airborne missile to which the NATO code-name AWL has been assigned. To date it has only been associated with the MiG-23 (Flipper) interceptor by Western observers, and its precise function is so far largely



Awl

a matter of conjecture. General configuration is rather similar to that of the American Sparrow IIIB, but it is estimated to be of greater weight and size with a probable length of about 5 metres.

In the absence of firm data, the method of guidance cannot be determined, but it is reasonable to assume that the Soviet authorities have examined both radar and infra-red forms. Alternative versions of Awl, equipped with either type of guidance may exist.

SUB SURFACE-TO-SURFACE WEAPON SYSTEMS

2221.411
INTRODUCTION

So far as is known, all the current weapon systems that come within the definition of this sub-section are carried by manned submarines. It is possible to envisage other arrangements; but international agreement has somewhat reduced (although by no means extinguished) enthusiasm for the development of unattended missile systems for deployment on the sea bed. The unmanned pre-programmed missile-launching submarine, however, remains a possibility: but so far as is known it is no more than this.

In terms of deployed strategic weapons the USA was until recently clearly in the lead, outnumbering the USSR by something like four to one. USSR deployment has recently been catching up rapidly, however, and in fact the terms of the interim agreement on offensive weapons, made at the same time as the Nixon-Brezhnev treaty in May, 1972, permit a greater deployment by the USSR than by the USA. In part this larger deployment is assumed to be offset by the more advanced MIRV techniques incorporated in the American missiles but it now seems virtually certain that the Russians will extinguish that lead before long.

Strategic Cruise Missiles

As noted in entry **1759.411** below, the United States authorities have initiated a development project for submarine-launched cruise missiles one outcome of which should be a strategic weapon.

The purpose of arming the US submarine fleet with such missiles is to introduce a new threat against which their potential enemies would have to take steps to protect themselves: such a project also has the advantage of lying outside the scope of the SALT agreements.

The USSR, of course, has extensive experience in the development and deployment of cruise missiles. Those that are currently known are generally regarded as tactical rather than strategic missiles although some may carry nuclear warheads. There can be little doubt, however, that if there is not already a submarine-launched strategic cruise missile available to the Soviet Navy there very soon will be.

CHINA (PEOPLE'S REPUBLIC)

2051.411
CHINESE SUBMARINE-LAUNCHED BALLISTIC MISSILES

No definite information is available on Chinese SLBM developments. The Chinese Navy has one ballistic missile submarine of the Soviet G class, built at Dairen in 1964. This has three vertical ballistic missile tubes in the enlarged conning tower. At present the armament of this submarine is believed by some to be short-range ballistic missiles with a range capability of perhaps 600 km – probably Serb missiles (**1153.411** below). Opinions on the subject differ, however, and there are those (including senior US officials) who believe that this submarine is unarmed.

Whether the Chinese authorities will seek to enlarge the capability of their naval forces in the SLBM direction or not is presumably a matter of priority. From what has so far been done in the fields of nuclear weapons and rocketry it seems likely that they have the required technological capacity; what has to be decided is how the total available missile development and manufacturing resources are to be allocated to ICBM, SLBM, IRBM, anti-aircraft and battlefield missile projects.

Official US opinion, as presented by Admiral Thomas H. Moorer in March 1974, is that the People's Republic is believed to be determined to develop both a submarine-launched ballistic missile and a modern ballistic missile submarine to go with it. It is now thought unlikely, however, that such a system could become operational before 1977. Whether or not the existing Chinese nuclear submarine is armed it is to be expected that it will be used for trials of a new missile. No other Chinese ballistic missile submarines are known but the possibility that one or more are under construction cannot be ruled out.

FRANCE

1134.411
MSBS SUBMARINE LAUNCHED BALLISTIC MISSILE

DESCRIPTION:

MSBS (Mer-Sol Balistique Stratégique) is a medium-range, two-stage submarine-launched weapon forming a vital part of the French nuclear deterrent force. In general concept it is similar to the American Polaris missile family. Size and weight are somewhat greater, however, and with the present version at least, range and the explosive power of the nuclear warhead are somewhat smaller.

The present (M-1) version of the missile is currently operational and is deployed in submarines of the SNLE (Sous-marines Nucléaire Lanceur d'Engins balistiques) class each of which is capable of accommodating 16 missiles in two rows of 8 launch tubes aft of the 'sail'. Of these submarines, *Le Redoutable* has been in service since 1971 and *Le Terrible* since early 1973. These are the first two of an initial series of SNLE, and *Le Foudroyant*, *L'Indomptable* and *Le Tonnant* will be in service before the end of 1978. Each submarine can launch all 16 missiles in 15 minutes. *Le Redoutable* and *Le Terrible* have both test-fired M-1 missiles under operational conditions. No details of these vessels' fire control and navigation systems have been released, but the latter must be assumed to be inertial, and the general mode of operation very similar to that employed by American and British submarines of this type.

Logistical support for the MSBS system is provided by the Ile Longue Naval Base in Brest Bay where there are the assembly and storage facilities necessary to keep the missiles in operational readiness.

Live testing of these missiles began in 1966 in the Sahara Centre near Hammaguir. The first underwater launches took place from a caisson at the Centre d'Essais de la Méditerranée, and then from the experimental, conventionally powered submarine, *Gymnote*. Final testing was handled by the Centre d'Essais des Landes offering a longer range with a target zone in the Azores.

CHARACTERISTICS – M-1 MISSILE.

Height: 10.4 metres
Diameter: 1.5 metres
Weight: 18 metric tons (approx.)
Guidance: Inertia with EMD Sagittaire digital computer
Propulsion:

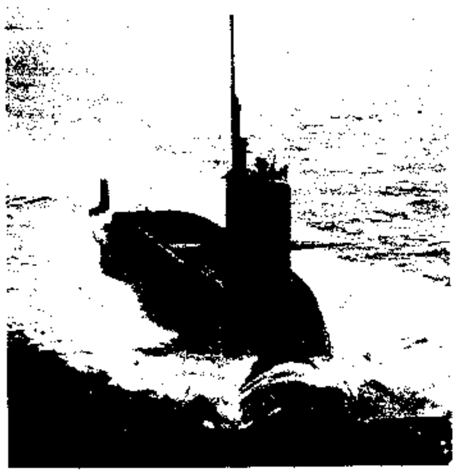
First-Stage: Type "904" motor in flow-turned vascojet 1000 casing containing 10 metric tons of solid propellant. Four gimballed nozzles for control.

Second Stage: "Rita" I motor in wound fibreglass casing containing four metric tons of solid propellant. An internal thrust vector system consisting of four freon jets spaced at 90 degrees round the single fixed nozzle is used for control.

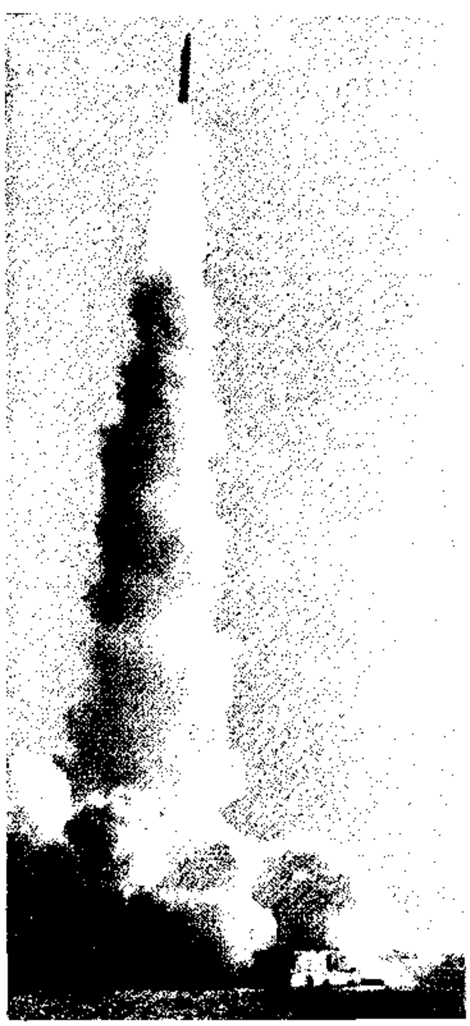
Warhead: Nuclear – reported to be 500 KT.

Range: 1,350 nm (approx) (2,500 km)

An improved version of the MSBS is now under development. Known as the M-2, its principal difference will be that of increased range. A new,

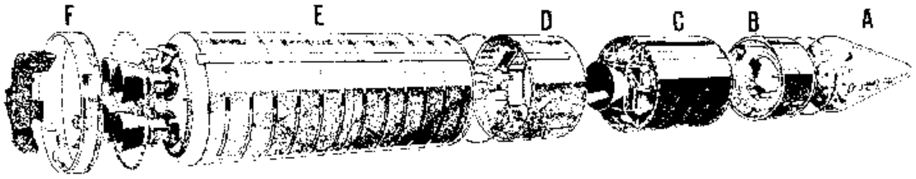


Le Redoutable



M.011 MSBS missile launch

higher performance, second stage – the Rita II – similar in principle but powered by 6 metric tons of solid propellant instead of 4, will replace the Rita I stage. The new missile will equip the third SNLE (*Le Foudroyant*) and the first two submarines will be modified to accept the new missiles during their normal refitting periods. The M 2 will have the same nuclear warhead as the M-1: from 1976 onwards, however, a new re-entry vehicle will be used. This will have a megaton-range thermonuclear warhead and penetration aids which will further increase the operational performance of the MSBS. This new configuration is called the M20.



The MSBS missile. A. Warhead. B. Control and guidance package. C. Second-stage motor D. Interstage fairing. E. First-stage motor. F. Skirt

MANUFACTURERS:

As in the case of the SSBS, the governmental agency in control is the Direction Technique des Engins and the industrial prime contractor is the Division des Systèmes Balistiques et Spatiaux of Aérospatiale, (SNIAS) whose responsibilities, in addition to the missile itself, include the on-shore assembly and check-out operations at the naval base, as well as the command and control launch procedures aboard the submarines.

Structures – Aérospatiale, SNECMA
Cases – Aérospatiale
Motors – SEP
Propellants – SNPE
Equipment – SAGEM, EMD, Matra, Souriau, LCT, Air-Equipement, Aérospatiale
Re-entry body – Aérospatiale
Nuclear charge – Commissariat à l'Energie Atomique
Integration – Aérospatiale
Environment – Electronic (Command & Control) – CII, SINTRA, SILAT

FRANCE / INTERNATIONAL

2219.421
SUBMARINE-LAUNCHED EXOCET

This is a proposal for an advanced version of the French Exocet missile (**1156.221**) that can be launched from a submerged submarine. Although no details have been published, it is assumed that the general characteristics of the missile will be not very different from those of Exocet – a range of some 40 km, for example, and a payload of some 700 kg.

Development of the new missile system was to be carried out in accordance with an Anglo-French agreement negotiated in mid-1969. The main contracting companies were the Missile Division of SNIAS for France and the British Aircraft Corporation for the UK. It is understood that the project has now been turned down, so far as the British authorities are concerned, in favour of the USGW (**2441.421**); but it is still possible that it will continue as a French project with or without collaboration by other countries.

STATUS:

No definite information

MANUFACTURERS:

Aérospatiale, rue Béranger, Chatillon-sous-Bagneux, France.

THE UNITED KINGDOM

2390.411
UK POLARIS MISSILES

DESCRIPTION:

Although the United Kingdom stopped developing strategic ballistic missiles when the Blue Streak project was cancelled, the country has retained many of the facilities that it was using for such development work; and the engineering teams have continued to work in many related fields. Although the Polaris missiles which equip the UK nuclear-powered ballistic missile submarines are largely of US manufacture, the contribution made by British industry is sufficient to justify giving the UK a separate listing in this sub-section.

The Royal Navy's ballistic missile submarines are equipped with the A-3 Polaris missile. These missiles, however, are supplied to the UK without warheads, and nuclear warheads of UK design and manufacture are fitted, together with re-entry bodies, fusing and arming devices, all developed and manufactured in the UK.

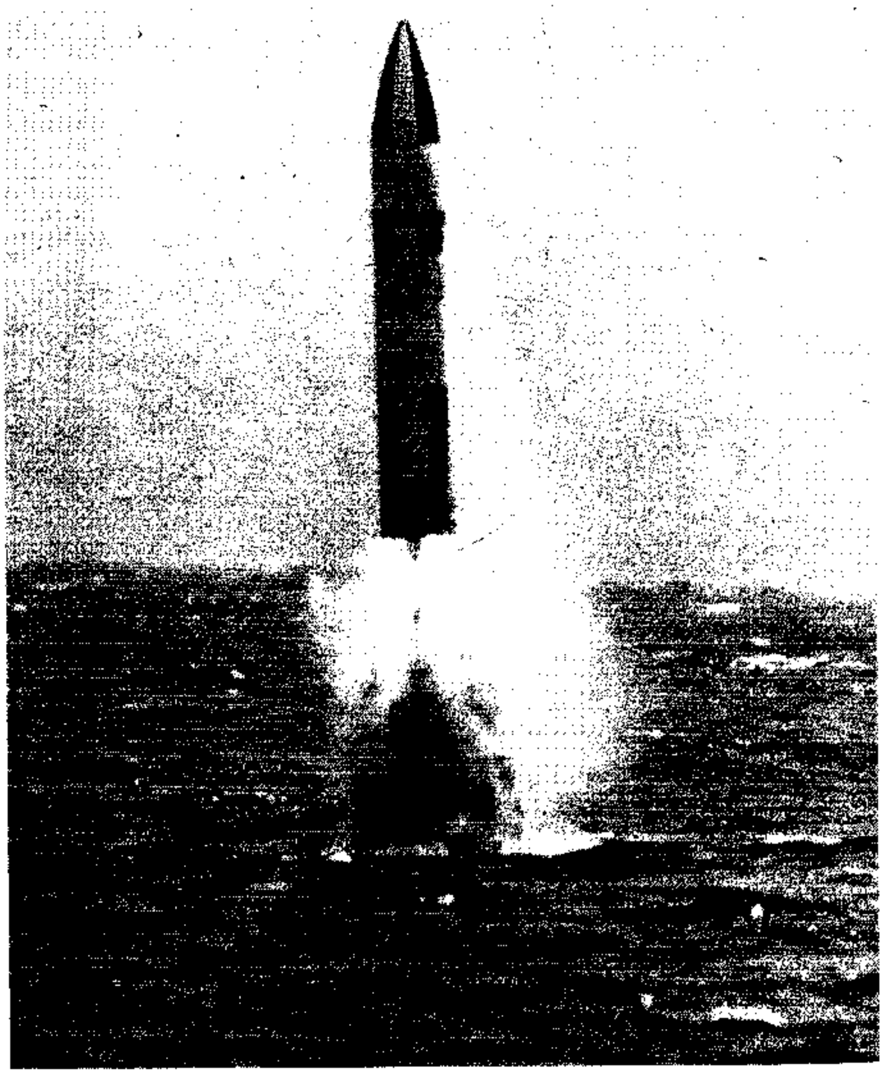
STATUS

It is widely agreed that something needs to be done to modernise the British force, but no information is available on the option that are being considered. An underground test explosion carried out in connection with the British programme in 1974, however, suggests that some agreed programme is being implemented.

MANUFACTURERS:

About 800 British firms are or were associated with the UK Polaris programme. Some of the major contractors are listed below.

Submarines:
Vickers
Cammel Laird
Nuclear Reactors:
Rolls Royce
Royal Navy Polaris School:
George Wimpey & Co.
Vickers
GEC-Marconi
British Aircraft Corporation
Sperry
EMI
Crew Training Simulator:
GEC Marconi



Royal Navy Polaris missile (MoD Royal Navy Photograph)

2441.421
UNDERWATER TO SURFACE GUIDED WEAPON (USGW)

DESCRIPTION:

Little information has so far been released concerning this project. In broad outline, however, the proposal is for an air-flight missile which can be launched from a submerged submarine, rise to the surface and thence travel as a conventional air-flight missile towards a surface target.

Clearly the project has quite a lot in common with the submarine-launched Harpoon project (**2797.411**) and possibly with the proposed submarine-launched Exocet (**2219.421**) which it has superseded as a British project. It should be stressed, however, that it is essentially a tactical weapon that is being proposed. the fact of launching through the submarine's torpedo tubes in any case limits the range of design opportunities; but although it is believed that a substantial range is among the desiderata it is also believed that any kind of strategic nuclear capability is not.

It is understood that the missile to be used is a derivative of the HSD/Matra Martel (**1022.311**) and that it will be enclosed in a capsule made of four detachable sections and of a size that is compatible with a 21-inch torpedo tube. This capsule, on launching, will be boosted from the torpedo tube by a rocket motor having sufficient energy to propel the missile clear of the water. When this happens the capsule and boost motor will be discarded, the missile's control surfaces will be deployed and it will fly under power from its main motor, following what is now becoming a conventional climb, dive and skim path towards its target.

STATUS:

The UK Ministry of Defence has placed contracts with British industry for the design of the USGW which is intended to replace the torpedo as the main armament of the nuclear-powered hunter-killer submarines in the Royal Navy.

Prime contractors for the missile are Hawker Siddeley Dynamics Ltd. supported by Marconi Space and Defence Systems Ltd for the guidance system and IMI Ltd for the propulsion system.

THE UNITED STATES OF AMERICA

1130.411
POLARIS A-2 (UGM-27B) FLEET BALLISTIC MISSILE

DESCRIPTION:

Polaris is a two stage ballistic missile powered by solid-fuel rocket motors and guided by a self-contained inertial guidance system independent of external commands or control. There are currently two generations of Polaris, A-2 and A-3. Polaris A-1 was officially retired from active duty when the USS Abraham Lincoln (SSBN 602), the last of the first five SSBNs to carry it, returned to the United States on 14 October 1965, for her initial overhaul and refit to A-3. By the time these words appear in print, the A-2 missile, too, should have been phased out of fleet service.

The 1,200 nautical mile (2,220 km) range Polaris A-1 was 8.53 m long, 137 cm in diameter, and weighed about 13,600 kg. Each of its motors exerted thrust through four nozzles in the motor base. Thrust vector (direction) control was exercised by devices called jetavators. Both first and second stage motor cases were made of steel.

The 1,500 nautical mile (2,780 km) range operational Polaris A-2 missile is similar to the A-1 in general appearance and diameter. However A-2 is 76 cm longer and uses a more powerful solid-propellant than A-1. New features include a second stage rocket motor case made of wound fibreglass instead of steel, and rotating nozzles instead of jetavators.

A thermo-nuclear payload is carried, the yield of which is reported to be about 800 kilotons.

Polaris missiles are deployed in vessels of the US Navy nuclear submarine fleet, each ship carrying a total of 16. More details of the Polaris fleet appear later.

OPERATION:

Missile guidance: The inertial guidance system used in Polaris was a refinement of earlier inertial systems and was the most compact of any US ballistic missile. The missile's guidance package consists of an inertial platform and a digital computer. The inertial platform is a gyro-stabilized set of three accelerometers. Once launch has occurred, the computer is in full control of the missile.

In-flight missile accelerations are measured by the inertial platform and integrated into velocities. These velocities are fed continuously to the computer. The computer constantly compares this attained velocity information with the required velocity received from the ship's fire control system prior to launch and stored within the computer memory.

When the missile has acquired that velocity which will permit the payload to continue on to the target on a ballistic trajectory, the computer issues a signal which commands separation from the second stage motor, and the payload continues on a ballistic trajectory to the target.

Navigation: Two positions must be known for missile launching: target and launcher. In the Polaris system this puts great importance on navigation since the position of the launcher is the position of the ship and is continuously changing. Several methods complement each other in the FBM submarine to provide a high order of accuracy in determining ship's position. Heart of the system is the Ship's Inertial Navigation System (SINS), a complex system of gyroscopes, accelerometers and computers, which relate movement and speed of the ship in all directions to true north to give a continuous ship position information.

The SINS installation differs between the various classes of US nuclear submarines. The 508 class of vessel is fitted with three Mk 2 SINS; the 608 class has two Mk 2 SINS; and 12 of the 616 class have two Mk 2 SINS. The first 19 vessels of the 616 class were fitted with three SINS of the same type. All of these inertial systems are produced by the Autonetics division of North American Rockwell as the N7 Mark 2 SINS guidance system.

Numerous equipments are included in the submarine navigation system to provide an all weather capability of verifying the accuracy of SINS. These include both optical and electronic devices.

In addition to astro-navigation the US Navy Transit navigation satellite, Loran and other position-fixing data sources are used for periodic updating of SINS.

Fire Control: The fire control system is a large digital geoballistic computer which processes coordinated data such as ship's location, local vertical true north target location and other data, and determines from these the proper trajectory for each of the 16 missiles at any given moment. Because many of these data change in value as the ship moves, the fire control computers can recompute all 16 trajectories every few seconds for transfer to the missile guidance computer memory store.

The fire control mechanism can prepare missiles for launch at the rate of about one per minute.

Two Polaris fire control systems have been produced by the General Electric Company for the FBM vessels. The first, the Mk 80, was originally installed in vessels of the SSB(N) 598 and SSB(N) 608 classes, but the five submarines of the former now have the Mk 84, following their conversion from A-1 to A-3 Polaris missiles. The Mk 80 fire control systems which were produced in Mod 0, 1, 2 and 3 versions, on these ships were probably converted to the Mk 84 at the same time as the missile conversion.

The Mk 84 fire control system is fitted in the 31 submarines of the SSB(N) 616 class.

Missile launching: Polaris missiles are launched from the submarine by an air ejection or a gas/steam generator system. On the latter a small fixed rocket is ignited and its exhaust directed through cooling water into the base of the launch tube. The missile is propelled from the tube, through the water and to the surface. At that point the missile's first stage rocket motor ignites and sends the missile on its way. Each launch tube has its own launching system independent of the other tubes. Vital parts of each missile are accessible for inspection and maintenance when loaded in the launching tubes and while the submarine is underway at sea.

Communications: VLF (Very Low Frequency) radio is the principal means of communication with submerged vessels of the USN FBM force, reception at these frequencies being possible to well below periscope depth. The Omega navigation system also operates in this part of the radio spectrum and could presumably be used as a further source of navigational data for up-dating SINS without any need for surfacing, although suggestions that the Omega system is indeed so used have been rejected by an official spokesman.

DEVELOPMENT:

Flight testing of Polaris began on 24 September, 1958, with the first launching of what was known as the AX series of test vehicles. After 17 AX flight tests, the pre-prototype tactical version, AIX, began flight tests on September 21, 1959, and during the next ten months, 30 AIX models were flown at the Atlantic Missile Range.

The 31st A-1 marked the first firing of a Polaris from a submerged submarine. On July 20, 1960, the lead Fleet Ballistic Missile submarine, USS George Washington, conducted a completely successful firing while submerged off Cape Canaveral. Less than three hours later, she launched a second successful A-1.

Development flight testing of the second generation Polaris A-2 began in November 1960 and continued in parallel with submarine firings of the Polaris A-1. Originally conceived as basically an A-1 with a 76 cm longer first stage, the A-2 developed into a missile with many advances over the A-1. Beginning late in 1961 a series of A2X missiles were modified to flight test certain subsystems and equipment designed for later use in the A-3. The first successful submerged launch of an A-2 came from the USS Ethan Allen on October 23, 1961, while cruising submerged off Cape Canaveral.

The first and to date only full systems launch of a US strategic missile occurred on May 6, 1962, when the USS Ethan Allen, cruising in the Pacific with Joint Task Force 8, successfully launched a Polaris A-1 with nuclear warhead. The nuclear detonation was successful.

1131.411
POLARIS A-3 (UGM-27C) FLEET BALLISTIC MISSILE

DESCRIPTION.

The A-3 version of Polaris represents a major re-engineering of the basic missile to achieve a 60 per cent increase in range for approximately the same weight and dimensions as the A-2 model.

Range of the Polaris A-3 is 2,500 nautical miles (4,630 km), much of this increase over the 1,500 nm (2,780 km) of the A-2 being attributable to reduced structure and component weight and the use of a new solid-propellant for the two-stage motor. Both stages of the A-3 motor are of glass fibre construction. The inertial navigation system of the A-3 missile is about 60 per cent smaller than that of the A-2.

There is also a difference in the external appearance, the later A-3 weapon having a constant circular cross-section along its length and a blunt rounded nose cone instead of the large and small diameter cross-sections which are a feature of the A-2. Overall length is increased by 15 cm to 9.55 m, but diameter and approximate weight remain the same at 137 cm and 13,600 kg, respectively.

In many ways the most significant difference between the two missiles is in the warhead. Initially, the A-3 missile was fitted with a single warhead of about 1 MT – not greatly different from that of the A-2. Subsequently, however an MRV warhead was developed for the missile; and most of those now in service have been fitted with a 3 × 200 KT MRV warhead.

OPERATION:

Targeting data for a variety of operational contingencies is carried aboard each submarine on patrol in the form of prepared magnetic tapes. This information is fed into the fire control system, together with continuous navigational data from SINS and sea state information from the ULCER system. The latter enables compensation to be made for currents which could affect the missile after it is ejected from the launcher tube.

DEVELOPMENT:

A series of A-2 experimentally modified Polaris missile launchings began in the latter part of 1961 to test freshly designed sub-systems and equipment for the A-3 version. The first successful launch of the new version was achieved at the seventh attempt, extensive static and ground testing being carried out between shots to isolate and cure specific problems. The first tube-launching at sea occurred on October 26, 1963. Entry into operational service with the US Navy was in September 1964.

It has been stated by the US Navy that each submarine on station in the Atlantic and Mediterranean has all 16 missiles ready to fire 96% of the time, 15 ready 99.9% of the time and 14 ready always.

STATUS:

Of the 41 fleet ballistic missile submarines of the US Navy, the five *George Washington* class were originally fitted with the Polaris A-1 missile, the five *Ethan Allen* class and eight of the *Lafayette* class with the A-2 missile and the remaining 23 *Lafayette* class submarines with the A-3 missile.

Subsequently the *George Washington* class have been converted to the A-3 missile; and the *Ethan Allen* class should have been similarly converted by the time these words appear in print. The 31 *Lafayette* class submarines will have their A-2 or A-3 missiles replaced by Poseidon (**1133.411**).

According to the latest available US official statements, all Poseidon conversions will be complete by mid-1977 – giving a total strength of 31 Poseidon submarines (496 launchers) and 10 A-3 submarines (160 launchers).

MANUFACTURERS:

More than 20,000 contractors and government agencies have been engaged in work on the American FBM system. Some major contractors and government agencies are listed below. Production of Polaris A-2 was completed in June 1964 and the A-3 production was complete in June 1968.

FBM Submarines:

Electric Boat Division, General Dynamics Corp. Groton, Connecticut

Newport News Shipbldg. and Drydock Co., Newport News, Virginia

Mare Island Naval Shipyard, Vallejo, California

Portsmouth Naval Shipyard, Portsmouth, New Hampshire

Submarine Propulsion:

Westinghouse Electric Corp., Pittsburgh, Pennsylvania

General Electric Corp., Lynn, Massachusetts

Navigation:

Autonetics Division, North American Rockwell, Anaheim, California

Sperry Gyroscope Co., Division of Sperry Rand, Inc., Great Neck, Long Island, New York

Communications:

Sylvania Electric Products Co., Buffalo, New York

Princeton Labs, RCA, Princeton, New Jersey

Bell Telephone Labs, Whippany, New Jersey

International Telephone and Telegraph Labs, Nutley, New Jersey

Fire Control:

General Electric Co., Ordnance Dept., Pittsfield, Massachusetts

Hughes Aircraft Co., Culver City, California

1133.411
POSEIDON C-3 (UGM-73A) FLEET BALLISTIC MISSILE

DESCRIPTION:

Two-stage, solid-propellant strategic missile designed for launching from submerged submarines of the US Navy. Successor to the Polaris A-2 and A-3 weapons currently deployed. Range of Poseidon is the same as for the Polaris A-3, 2,500 nautical miles (4,630 km), but weight is more than doubled at 29,480 kg. Dimensions are correspondingly greater at length 10.36 m, diameter 188 cm, but the new missiles are capable of deployment in the launch tubes of existing Polaris submarines without major modifications to the ship.

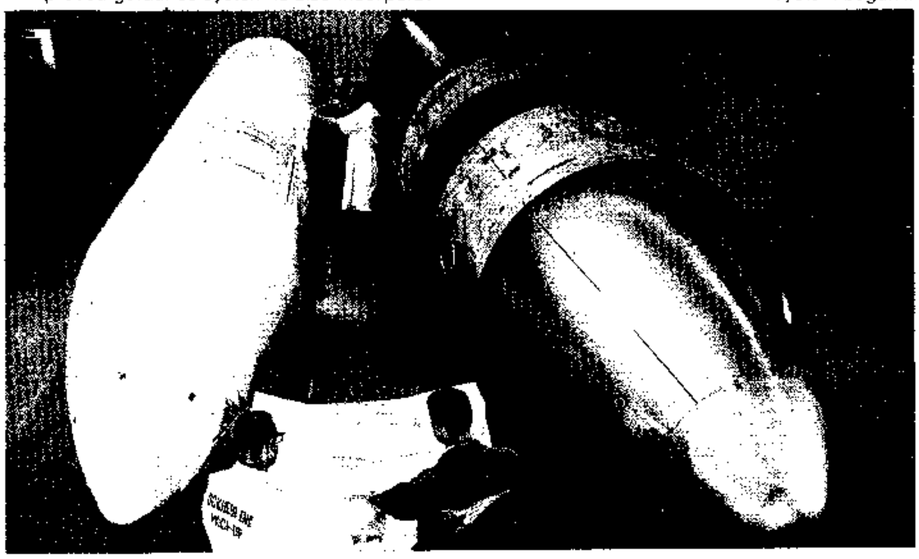
A considerably increased nuclear payload consists of an MIRV warhead which enables a single Poseidon to be used against a number of targets. An improved guidance system is also incorporated which provides double the accuracy, it is claimed, of the earlier weapons.

A new fire control system, Mk 88, is being produced for the Poseidon system by the General Electric Company. This interfaces with a new version of the Autonetics SINS (Ships Inertial Navigation System), the missile and the launcher. Mk 88 performs target calculations, insertion of data into the guidance system, test and checkout launch order, and sequence control.

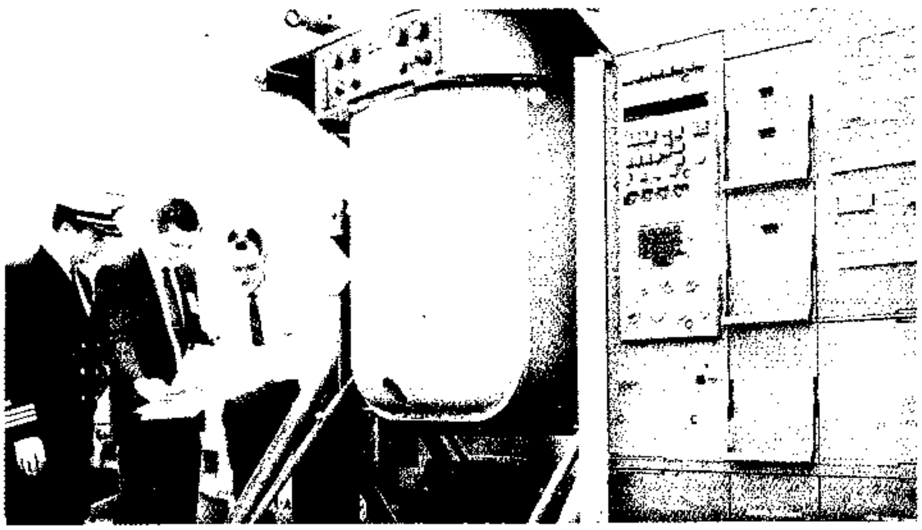
DEVELOPMENT:

The first flight model of Poseidon was launched on August 16, 1968, from Cape Kennedy, Florida. The fourteenth launch, in December 1969, was the first complete test of the weapons system, including the launcher, control and missile subsystems. Development flight testing was completed in June 1970 with 14 of 20 launches described as successful by the Navy.

Work on the Mk 88 fire control system began in



Comparison of Polaris A-3 (left) *with Poseidon C-3 Fleet Ballistic Missile*



New version of Autonetics N7 SINS (Ship's Inertial Navigation System) for Poseidon carrying submarines

First operational launch of a Poseidon missile from the SSB(N) James Madison *on the 3rd August, 1970* (US Air Force photograph)

1965 and the first prototype was delivered by GE in 1968.

STATUS:

After a delay of three months caused by production line problems, Poseidon became operational on March 31, 1971, when the USS *James Madison* deployed on patrol from Charleston, South Carolina.

Prior to initial deployment there had been nine Poseidon firings from FBM submarines, the first having been launched from the USS *James Madison* on August 3, 1970.

Thirty-one vessels of the Navy's FBM force are being fitted with the C-3 Poseidon. The conversion programme began in February 1969, and is scheduled for completion in mid 1977. Only submarines of the 'Lafayette' class are being converted. By the beginning of March, 1974, 20 conversions had been completed and deployed, two were at the pre-deployment stage, six were undergoing conversion and three had not been started. The Poseidon test programme ran into difficulties in 1973 when several failures occurred as the results of a variety of component malfunctions. A retrofit modification programme has since been devised and is expected to restore the SLBM force to its specified standards of reliability and accuracy.

MANUFACTURERS:

Lockheed Missiles & Space Company, PO Box 504, Sunnyvale, California 94088, USA – prime contractor.

General Electric Company, Ordnance Systems, Electronic Systems Division, 100 Plastics Avenue, Pittsfield, Massachusetts 01201, USA – Mk 88 fire control system.

Autonetics Division, North American Rockwell Corporation, 3370 Miraloma Avenue, Anaheim, California 92803, USA – SINS.

2797.421
SUBMARINE-LAUNCHED HARPOON MISSILE

DESCRIPTION:

The basic Harpoon ship-to-ship operational concept (see **2641.221**) has been extended to a submerged launch by placing the missile in a capsule for the through-water part of the launch trajectory. This capsule has been designed to be compatible with standard submarine torpedo tubes and torpedo loading and handling equipment.

The capsule, with its booster motor, is accelerated from the torpedo tube by pneumatic or hydraulic force and rises to the surface because of its buoyancy. The path to the surface taken by the capsule is controlled by aft fins mounted on the capsule. A broach sensor is fitted to the capsule and signals when the surface is reached, initiating a sequence of events which separates the fore and aft ends of the capsule and ignites the booster. The missile then flies out of the capsule and follows a standard ship-launched missile flight plan to the target.

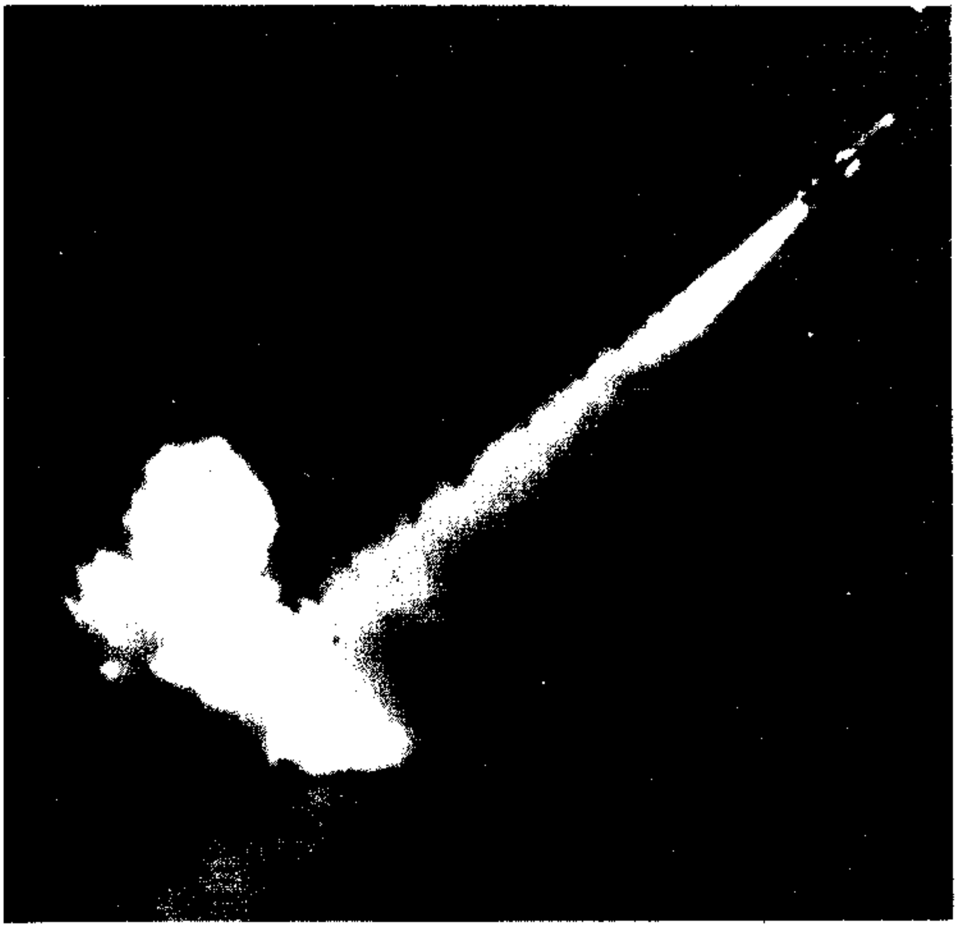
Targeting is accomplished by inserting into the computer range and bearing data obtained from ship's sources or third party observers on the surface or airborne.

STATUS

The encapsulated version of Harpoon is in full development and scheduled for deployment on US Navy attack submarines in the mid 1970s.

MANUFACTURER:

McDonnell Douglas Astronautics Company, PO Box 516, St. Louis, Missouri.



Submarine-launched version of Harpoon in flight

1759.411
SUBMARINE-LAUNCHED CRUISE MISSILE (SLCM)

DESCRIPTION:

This programme, also known as the US Navy Cruise Missile because of the intention of providing for surface-ship launching and possibly air launching, is a development project to provide US submarines with an underwater-launched cruise missile for both strategic and tactical purposes. The programme is paralleled by the ALCM (Air-Launched Cruise Missile) project of the USAF and both services have been instructed to ensure that there is maximum commonality between the two weapons. Each service has been given prime responsibility for one broad aspect of the SLCM/ALCM system: the turbofan cruise motor is a USAF responsibility, and the USN will take the lead in guidance system development.

Both tactical and strategic versions of SLCM are to be suitable for launching from standard size torpedo tubes. The tactical model will have a range of 300 nautical miles (555 km) or more and is likely to be armed with a conventional warhead for anti-ship, and possibly shore bombardment, missions. The strategic version's maximum range is to be about 1,500 nautical miles (2,780 km) and a nuclear warhead will be available. In both instances cruising speed will be subsonic, in the interests of range, and at low level for optimum

This artist's impression attempts to show all phases of a submarine launched cruise missile launch from submarine to cruise, but is best regarded as indicative of the general configuration of the missile penetration capability.

The guidance system for the cruise phase is expected to be a development of the TERCOM (Terrain Comparison) technique upon which the USN has been working for some years (see also entry **2719.111**). Equipment which has been used in this project includes a Honeywell APN-194 radar altimeter, Texas Instruments 2520-2 digital computer, and a Singer-Kearfott ASN-90 inertial navigator. The last of these items is essential to provide navigational data during over-water legs of the cruise flight path and during breaks in the data on terrain contour-matching which is the basis of the TERCOM technique. The combination of TERCOM and inertial navigation is called TAINS – Tercom-Aided Inertial Navigation System. Terminal guidance is likely to be by active radar homing. From what is known of these navigation techniques, it appears that TERCOM has no application over flight paths that do not pass over land. This suggests that there may eventually be three guidance package options for various SLCM applications: TAINS for the strategic version used to attack heavily defended land targets; straight inertial for tactical SLCMs intended solely for anti-ship operations; and TAINS for tactical SLCMs intended for shore bombardment.

STATUS:

The US Fiscal Year 1975 budget allocated $45 million for a competitive flight demonstration programme to provide information upon which to base a decision to develop either or both variants of SLCM.

2840.411
TRIDENT (C-4) UNDERSEA LONG-RANGE MISSILE SYSTEM (FORMERLY ULMS)

DESCRIPTION:

What was formerly called ULMS (Undersea Long-range Missile System) and has now been given the name Trident is a seabased intercontinental ballistic missile now being developed as a successor to the US Navy's Polaris/Poseidon programme. Development of the system was somewhat delayed as a result of the debate over whether the United States should continue to improve existing land-based strategic systems (i.e. Minuteman) or move its nuclear deterrent force to sea. However, ULMS development was strongly endorsed by the Secretary of Defence in early 1970 as an effort to counter recent technological developments and the decision by the USSR to undertake a worldwide anti-submarine effort. In March 1971 the Secretary of Defence reiterated his support for ULMS, terming it a major factor in future strategic force planning and in 1972 he announced that the programme would be accelerated so that the first Trident submarine could be operational by 1978 – two to three years ahead of the original plan.

Subsequently, however, the shape of the programme was changed – largely as a result of the absorption into it of what was previously a separate proposal for extending the range of the Poseidon missile – and now involves the development of two new missiles and a new submarine. The first missile – variously known as Expo (for extended-range Poseidon), ULMS-1, Trident 1 and now C-4 – will essentially be an extended-range Poseidon (7,000 km capability) and it will be retrofitted to the existing Poseidon submarines; it will also, pending the availability of the second missile, be used as initial equipment for the new Trident submarine. It will carry the Mk 500 re-entry vehicle (see **2708.111**) and will be powered by first, second and third-stage motors all specially developed jointly by Thiokol and Hercules Inc.

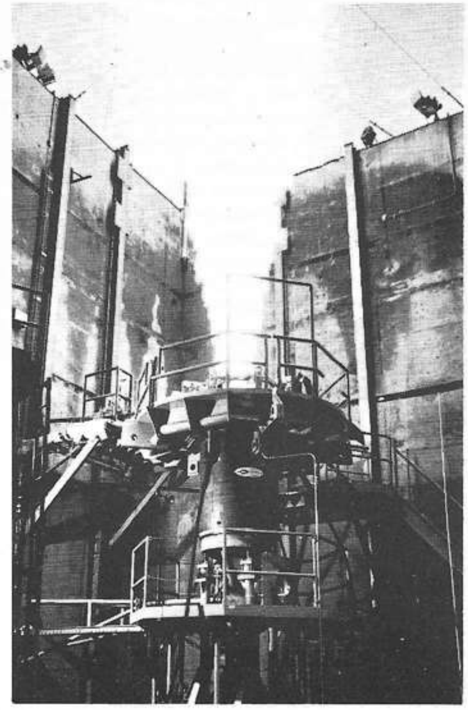
The second missile is expected to have a range of nearly 10,000 km and will be able to be launched only from the new submarine. This submarine is expected to be roughly twice the size of a 'Lafayette' class submarine and it will carry about 24 Trident missiles.

The Trident submarine is expected to be quieter than the existing vessels and be capable of reaching greater depths. Modular construction techniques will be used to reduce maintenance costs and in-port time and it is said that it will have an increased alert rate whereby a smaller force can maintain a given number of launchers on alert. The submarine will also carry an improved sonar unit and an advanced defensive weapons system.

The extended range of the Trident missile will permit the Trident fleet to operate from some 60 million square miles of ocean rather than the 3.5 million square mile range of the Poseidon fleet. The submarines could also be based exclusively in continental US bases, eliminating the dependence upon foreign ports.

STATUS:

Development work has started on the first Trident submarine, of which ten are to be built – the remaining nine being started at a rate of two per year beginning in FY 1975. The programme for the C-4 missile has been put back from its original operational date of 1977-78 to late 1978. The initial operational date for the Trident submarine is also in FY 1979. First fittings of the C-4 missile may therefore be in the Trident submarine instead of in the 'Lafayette' class as originally intended; nevertheless it is still planned to retrofit C-4 missiles in place of Poseidon in ten submarines – but not starting until early 1979. The new Trident missile will not be operational until the early 1980s.



Test firing of third-stage motor for the C-4 missile. This was the first test in which the United Technology Centre's "Techroll" fluid bearing was used in the steering device

MANUFACTURER:

Prime contractor: Lockheed Missiles & Space Company.

THE UNION OF SOVIET SOCIALIST REPUBLICS

2946.411
RUSSIAN SUBMARINE-LAUNCHED BALLISTIC MISSILES

As with so many other classes of Russian weapons there is little unanimity among Western observers regarding the nature, nomenclature, performance and deployment of the submarine-launched ballistic missiles of the Soviet Navy. The confusion is not reduced by the use, by the US authorities, of a single alphanumeric code series to cover both ship- or submarine-launched cruise missiles and SLBMs.

What does appear to be reasonably generally agreed is that the Y-class nuclear submarines are equipped with the Sawfly (**1154.411**) missile and that these submarines carry 16 of these missiles. From more than one source comes the suggestion that this is the missile that is known by the US alphanumeric code as SSN-6.

From various sources come identification of the SSN-4 with Sark (**1152.411**) and the SSN-5 with Serb (**1153.411**) – the latter being somewhat better favoured as a suggestion than the former. Another usually well-informed source, however, denies both identifications; moreover, Admiral Moorer, at that time Chairman of the US Joint Chiefs of Staff, making his FY 1975 Military

Z-V class Russian submarine – an early missile carrier

Posture statement in February 1974, illustrated it with some silhouettes of Russian SLBMs which appear to identify the SSN-5 with Sark, SSN-6 with Serb and SSN-8 with Sawfly. Although the Admiral's sources of information must be among the best available, we have seen mistakes in diagrams of this kind on previous occasions and choose not to accept these identifications at present.

The accompanying table gives what is believed to be a reasonable indication of current missile deployment. To minimise confusion the missiles are described only by their NATO code-names.

Scud-A missiles, referred to below, were probably used for early experiments and are no longer in naval service (see **2969.111** for details). For Sawfly (ER) see under Sawfly (**1154.411**).

Soviet Missile-equipped Submarines

Class	Propulsion	Missile	Number of Launchers
C	Nuclear	Shaddock-type	8
D	Nuclear	Sawfly (ER)	12
E1	Nuclear	Shaddock-type	6
E2	Nuclear	Shaddock-type	8
G1	Conventional	Sark (formerly Scud-A)	3
G2	Conventional	Serb	2
G3	Conventional	Serb	3
H1	Nuclear	Sark	3
H2	Nuclear	Serb	3
J	Conventional	Shaddock-type	4
W	Conventional	Shaddock-type	2-4
Y	Nuclear	Sawfly	16
Z-V	Conventional	Sark (formerly Scud-A)	2

1152.411
SSN-4 (SARK) SUBMARINE-LAUNCHED BALLISTIC MISSILE

DESCRIPTION:

Sark is the NATO code-name assigned to what has come to be regarded as the prototype Soviet submarine-launched strategic missile.

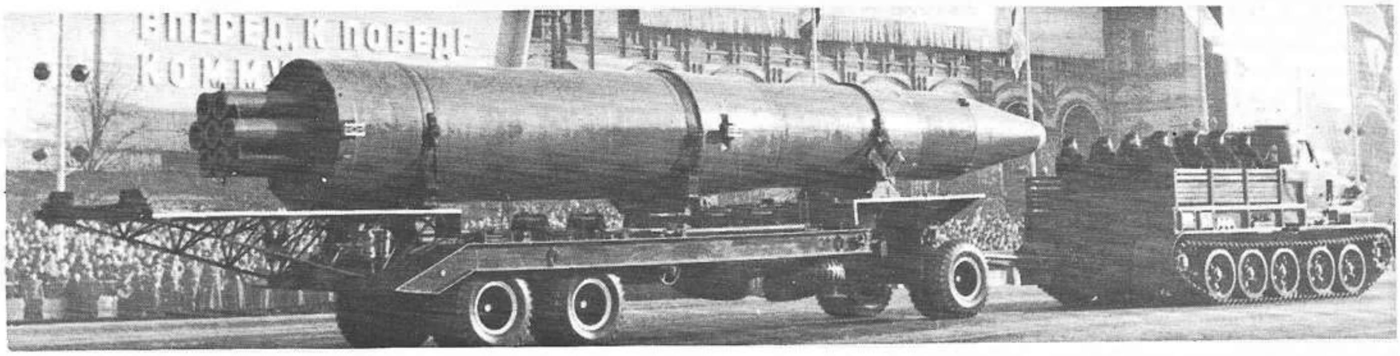
In general appearance it is similar to the American Polaris A-2 weapon of the same type, however it is estimated to be considerably larger with a length of 15 m and a diameter of 180 cm. Launch weight has been estimated at between 18 and 20 tons. Sark is believed to be a two-stage solid-propellant powered vehicle with a probable range of about 650 km. It should be noted, however, that at least one well-known observer of the Soviet naval scene has recently published figures that are all substantially smaller than the above – notably the range which is given as some 600 km. All seem to agree, however, that the missile is inertially guided.

STATUS:

Sark was first fitted in modified Z-class (Z-V) submarines following earlier installation of a missile similar (and probably identical) to Scud-A (**2969.111**). A test firing is believed to have taken place in 1955. Few if any of these submarines remain in service in this form.

Subsequent Sark fittings were in the early G-class (G-1) submarines (again preceded by Scud-A). One of these submarines is in the fleet of the People's Republic of China (**2051.411**). The early H-class nuclear submarines (H-1) were also fitted. Z-V submarines carried two missile launch tubes, G-1 and H-1 submarines three each.

In all these fittings Sark was installed for surface launching; and the sole justification for including it in this section is its connection with later SLBMs which could be launched from submerged submarines. Some observers claim that it has never in fact been an operational weapon – but the point is of little relevance because it is almost certainly not operational now.



Sark SLBM

1153.411
SSN-5 (SERB) SUBMARINE LAUNCHED BALLISTIC MISSILE

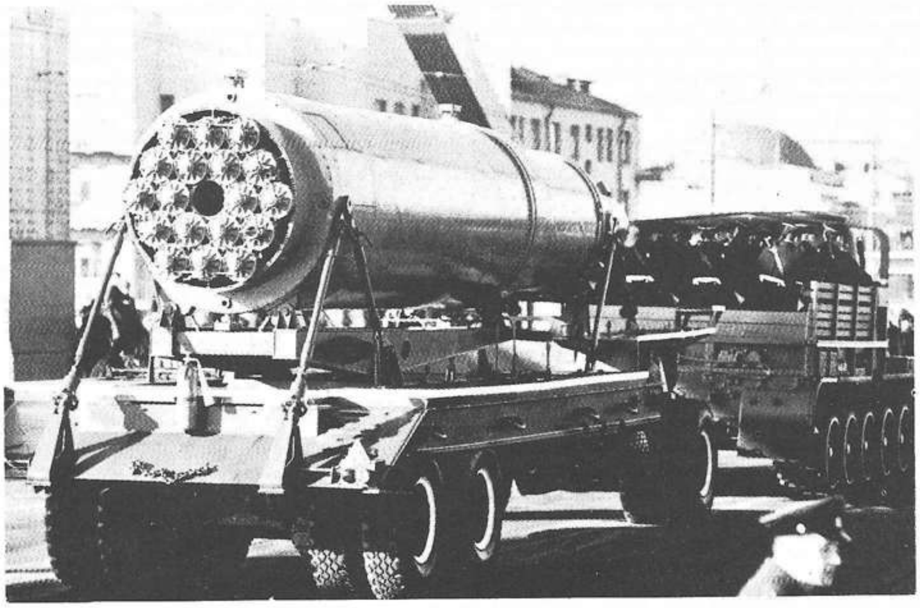
DESCRIPTION:

Serb is the code-name assigned by NATO to the successor to the Sark (**1152.411**) Soviet submarine-launched ballistic missile. Serb has been described as representing the second generation in this class of missiles in the USSR.

Like its forerunner, Serb is similar in appearance to the Polaris A-2 missile in service with the US Navy, and it is understood to be a two-stage solid fuel vehicle with inertial guidance. In size it conforms more closely with the dimensions of Polaris than does Sark, which is appreciably larger. Estimated Serb dimensions are: length 10 m, maximum diameter 1.5 m. Launch weight has been estimated at around 18 tons. While there is fairly close agreement, among the various authorities on these dimensions, there is far from being agreement on the missile's range capability. Estimates vary from about 1,200 km to about 2,400 km. A single re-entry vehicle with a warhead in the megaton range is carried.

When the Serb missile was displayed in the November 1967 parade, what is apparently a different ejection system to that employed in American submarine launcher tubes was revealed. At the base of the missile there is a cluster of 18 small, electrically fired cold-gas nozzles which are assumed to be used to eject the missile from the sealed launcher tube. On passing clear of the submarine, the section carrying these gas motors is probably jettisoned from the main missile body by means of explosive bolts fired when the first stage ignites.

It is probable that Serb was originally intended for installation in E-class nuclear submarines, but these were switched to a cruise missile role by a 1957-58 decision, and the missile when completed was retrofitted to G-class and H-class submarines in place of Sark. First submarine launch is believed to have been in March 1962.



Rear end of the Serb submarine-launched ballistic missile showing gas jets for ejection from launch tube

STATUS:

Operational in the later G-class (conventional) and the later H-class (nuclear) submarines on scales of two or three launchers per submarine.

1154.411
SSN-6/8 (SAWFLY) SUBMARINE LAUNCHED BALLISTIC MISSILE

DESCRIPTION:

It is probable that two missiles, known to the US authorities (or so it seems) as SSN 6 and SSN-8, are at present covered by the single NATO designation Sawfly. Up to the time of going to press, at least, there has been no news of a new name for the later of these two missiles.

It is generally agreed that the missile is some 15 m long and 1.8 m in diameter, that it has a launch weight of around 20 tons, that it is powered by a two-stage solid-propellant motor and is inertially guided. Range is variously estimated between 2,700 km and 3,500 km.

Until recently the missile was believed always to be equipped with a single re-entry vehicle with a warhead in the megaton range. Since our last edition went to press, however, it has been reported that the SSN 6 has been fired with a warhead of the MRV (but not MIRV) type.

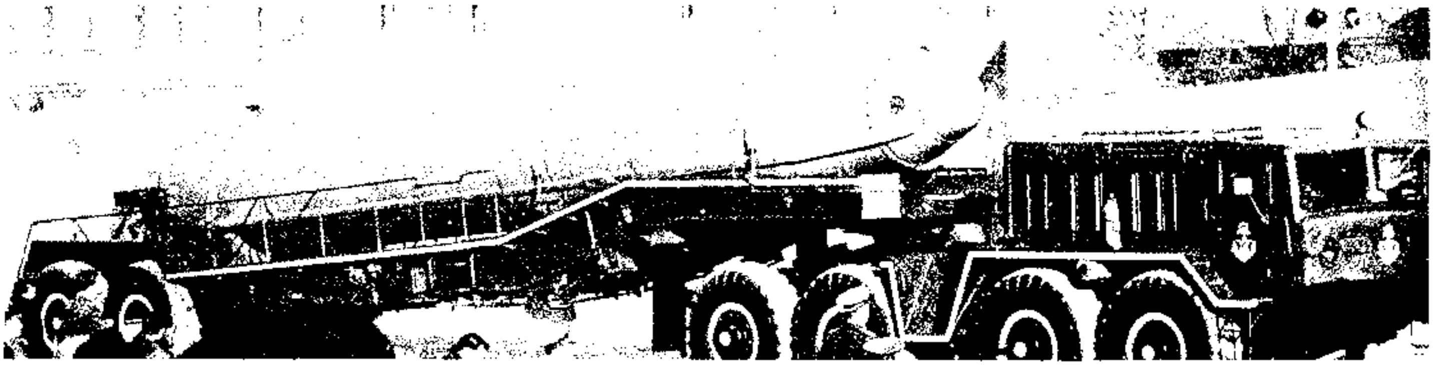
STATUS:

So far as is known, Sawfly is being installed only in the Soviet Y-class nuclear submarines. Each submarine is equipped with 16 launch tubes.

Sawfly (ER)

What is, according to some observers, a new missile or, according to others, an improved version of the Sawfly missile just described is known by the US alphanumeric designation SSN-8.

No identified photographs of the missile have yet been seen but information from official US sources suggests that the new missile is indeed a – probably larger – version of Sawfly. The name Sawfly (ER) has no official standing and is intended simply to indicate the most important characteristic of the new missile – that it has a range of some 7,500 km which is greater than any operational US SLBM. Sawfly (ER) is now operational in D-class submarines. It is also reported that the missile has been tested with a warhead of the MIRV type; and although this is not yet an operational warhead it seems likely that it will be operational before the American C-4 MIRV missile (**2840.411**) enters service. The latter, of course, is likely to have a much more sophisticated warhead than that which the Russians are likely to be able to deploy in the time available.



Sawfly submarine-launched ballistic missile

2987.411
SSN-7 SUBMARINE LAUNCHED CRUISE MISSILE

DESCRIPTION:

Little is known about this weapon other than that it is one of the family of cruise missiles developed in recent years in the Soviet Union, that it is carried by C-class Soviet nuclear submarines, on a scale of eight launchers per submarine, and that it can be launched while the submarine is submerged.

The missile is said to have autopilot control and presumably also has some form of homing system. Range has been variously reported between about 45 and 55 km; and it has been suggested that over a large part of its flight path it operates as a surface skimmer.

The submarine launch capability of this missile is undoubtedly one of the causes of the recent flurry of interest in submarine-launched tactical missiles among NATO countries. Most proposals currently under consideration in these countries however, contemplate the use of standard torpedo tubes as launchers – presumably because of the difficulty of retrofitting anything larger without denying the submarine the option of firing conventional torpedoes. The C-class submarine however, was designed from the outset to carry both missiles and torpedoes and was thus not so restricted in its choice of missile design as are the NATO designs.

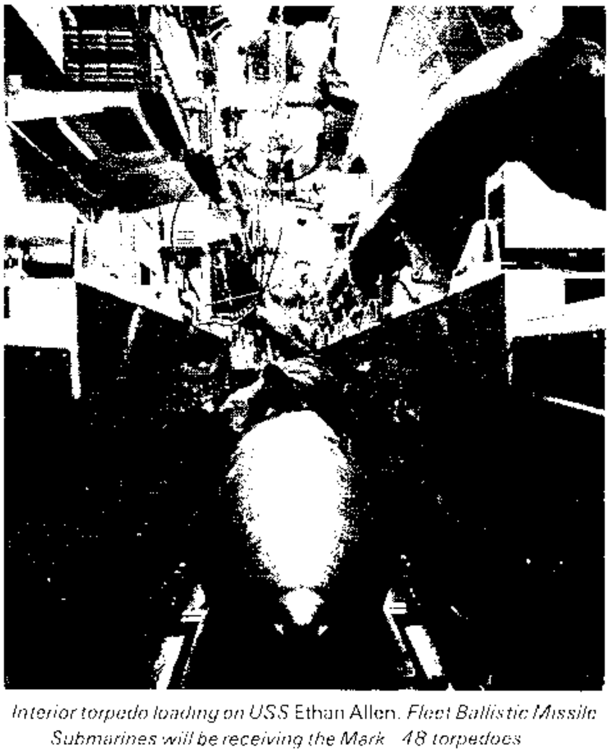
TORPEDOES

2295.441
INTRODUCTION – TORPEDOES

Torpedo development has long been one of the more neglected areas of weapon system activity; and although advances in relevant technologies have been reflected in a number of new designs in the past thirty years or so, a surprisingly large number of torpedoes whose designs date back forty years or more are still in service.

Since the emergence of the nuclear powered ballistic-missile submarine (SSBN) as a major strategic weapon, however, fresh impetus has been given to the development of the anti-submarine torpedo as one of the few types of weapon that offered an opportunity of countering the SSBN threat. Some of the development programmes concerned with this problem are now coming to fruition but others are just starting.

As explained in the introductory note on surface-to subsurface weapons (**2293.141**) the fact that some torpedoes can be used in two or more different roles makes it more sensible to group all torpedoes together rather than separate them by function. The entries set out below, however, are known not to be exhaustive – as the brevity of some descriptions indicates, information on some torpedoes is not easily come by; and the reader is also invited to consult the tabulation in Section 4 (**2296.444**) which – while still not exhaustive – contains some sketchy data on a few torpedoes that are not listed below in addition to tabulated data on those that are.



Interior torpedo loading on USS Ethan Allen. *Fleet Ballistic Missile Submarines will be receiving the Mark 48 torpedoes*

FRANCE

7501.441
ACOUSTIC TORPEDOES L3, E14 & E15

DESCRIPTION:

These torpedoes, which are further described individually in the entries that follow, have been designed with as many common parts as possible.

The weapons systems use part of the equipment pertaining to the submarine weapons of frigates and submarines. The sonar equipment detects, identifies and gives the position, route and speed of the target and, depending on the type of sonar, the depth of submergence. From this data, the directional launching system determines the straight path leading the torpedo near the target and conveys the relevant information to the torpedo tube stations and to the torpedoes. The torpedo follows this route until its homing equipment picks up the target. This then guides the torpedo either to impact or sufficiently close to the target to cause the proximity firing mechanism to operate.

Speed and range performances are selected to match the ranges of the sonar equipment carried by current French vessels.

The effective area of the explosive charge is consistent with the accuracy of self-guidance and with the operating requirements of the proximity fuse.

Propulsion is provided by a high-speed electric motor in series which drives, via a differential inverter-reducer, two contra-rotating propellers. The motor is rated from 40 kW (L3 and E14) to 50 kW (E15). Energy is provided by a storage battery comprising 76 (L3 and E14) or 120 (E15) Cd-Ni cells A/hr. The propulsion motor, operating as a rotary converter, powers the acoustic self-guidance system, and supplies the magnetic firing system and its ancillaries (50 V, 400 Hz, single-phase).

An automatic pilot guides the torpedo during the approach phase: it consists of an electric gyroscope which is started by air pressure within 0.4 second, and operates in conjunction with a depth regulator that controls the rudders via two pneumatic servo-motors. A 250-barye air tank starts the gyroscope briskly and supplies the servo-motors and the operating gear that sequences the various components.

OPERATION:

The L3 torpedo which is a strictly anti-submarine weapon incorporates the AS-3 active acoustic self-guidance system. Ultrasonic pulses are transmitted from and received by a bank of magnetostrictive transducers pendulated in the torpedo nose, the arrangement being such as to enable range bearing and elevation to be measured.

Location in azimuth and elevation is used to guide the torpedo according to a pursuit curve: the self-guidance system sends to the servo-motors, via electric valves that bypass the automatic pilot, the commands providing diving, rising and lateral control. These commands are applied for about the duration of the interval between successive pulses and cease as soon as the self-guidance system no longer confirms them.

A pendular system restricts the angle of trim of the torpedo from +10 deg. to −40 deg.

As the torpedo nears the target, the pulsed rate increases so as to improve the accuracy of pursuit and of the acoustic exploder mechanism.

On reception of a first distance echo less than 20 metres away, the exploder mechanism is triggered, bringing about explosion of the charge 3.5 seconds later. (If used for range practice, an adjuster stops the torpedo when 150 metres from the target.) If the torpedo overshoots the target beyond its assumed position, it proceeds with a specific search run.

If after a computed time the torpedo has not detected the target at the previous position it starts a circular search (if in shallow waters) or a helicoidal search (if in deep water).

The E14 and E15 torpedoes can be used only against surface ships or against noisy submarines when close to the surface.

The E14 torpedo has the same geometry and mechanical features as the L3 but the self-guidance system is passive. A bank of four transducers, in conjunction with a phase detector detects the target-radiated noise within a one-kHz bandwidth. This unit supplies two voltages whose difference enables it to locate the target in azimuth. After amplification and when these voltages have reached a given value, the self-guidance system sends lateral control commands by means of electric valves whereby the servo-motors abut against a limit switch (on/off control).

On nearing the target, the self-guidance system initiates the counter-command. The torpedo rotates in the same direction until it receives the counter-command. This avoids "break-off" of the torpedo when nearing the bows of the target, or permits resumption of an attack that aborted owing to the proximity fuse.

The magnetic proximity fuse system (M-7) is passive. Two probes detect the space variation of the magnetic field. When the torpedo passes under the target a signal of significant form develops which triggers the exploder mechanism of the charge. The range is about four metres under the hull of a frigate.

The protective system is designed so that arming of the exploder system and the authorisation to transmit the self-guidance system commands cannot take place until a 350-metre run from emergence from the torpedo tube has been accomplished.

The E15 torpedo has the same self-guidance system as the E14 but the geometry, range and explosive charge are different.

MANUFACTURERS:

Manufacturer – CIT-ALCATEL, Division Marine, 33 rue Emeriau, 75725-Paris CEDEX 15, France.

1163.441
E14 ACOUSTIC TORPEDO

DESCRIPTION:

Conventionally-shaped, submarine-launched, anti-ship (or anti-submarine in certain circumstances) torpedo with strong body in light alloy and laminated nose cone, with the following five compartments:

(1) acoustic passive self-guidance and electro-magnetic firing;
(2) the explosive charge and the inertial firing system;
(3) accumulators;
(4) air tank and automatic pilot;
(5) electric motor for propulsion.

CHARACTERISTICS:

Length: 168" (4,291 mm)
Diameter: 21" (533.4 mm)
Weight: 900 kg
Speed: 25 knots
Range: 5,500 metres
Explosive Charge: 200 kg
Submersion: Can be set within the range 6 to 18 metres (continuously variable)
Guidance: Acoustic, passive, average range 500 metres
Firing: Contact (inertial) and influence (magnetic)
Target: Surface vessel from 0 to 20 knots and submarine at shallow depth

STATUS:

Quantity production. The equipment is in service with the French Forces.

MANUFACTURERS:

CIT-ALCATEL, Division Marine, 33 rue Emeriau, 75725-Paris CEDEX 15, France.

Programme Direction – DTCN, 2 rue Royale 75 – Paris 8e.

1164.441
E15 ACOUSTIC TORPEDO

DESCRIPTION:

Conventionally-shaped, submarine-launched, anti-ship (or anti-submarine in certain circumstances), torpedo with strong body in light alloy and laminated nose cone, is a lengthened version of the E14 model 1 torpedo. It has the following five compartments:

(1) acoustic passive self-guidance and electro-magnetic firing;
(2) the explosive charge and inertial firing;
(3) accumulators;
(4) air tank and automatic pilot;
(5) electric motor for propulsion.

CHARACTERISTICS:

Length: 6,000 mm
Diameter: 550 mm
Weight: 1,350 kg
Speed: 25 knots
Range: 12,000 metres
Submersion: Can be set within the range 6 to 18 metres (continuously variable)
Guidance: Acoustic, passive, medium range
Explosive Charge: 300 kg
Firing: Contact (inertial) and influence (magnetic)
Target: Surface vessel from 0 to 20 knots and submarine at shallow depth

STATUS:

Quantity production. The equipment is in service with the French Forces.

MANUFACTURERS:

CIT-ALCATEL, Division Marine, 33 rue Emeriau, 75725-Paris CEDEX 15, France.

Programme Direction – DTCN, 2 rue Royale, 75-Paris 8e.

1165.441
L3 ACOUSTIC TORPEDO

DESCRIPTION:

Conventionally-shaped, ship-launched or submarine-launched, anti-submarine (to 300 m) torpedo with strong body in light alloy and laminated nose cone, with the following five compartments:

(1) acoustic active self-guidance and electro-magnetic firing;
(2) the explosive charge inertial contact firing system;
(3) accumulators;
(4) air tank and automatic pilot;
(5) electric motor for propulsion.

CHARACTERISTICS:

	21" version	550 version mod. 1
Length:	170" (4,318 mm)	4,300 mm
Diameter:	21" (533.4 mm)	550 mm
Weight:	900 kg	910 kg
Speed:	25 knots	25 knots
Range:	5,500 metres	5,500 metres
Max. submersion:	300 metres	300 metres
Explosive charge:	200 kg	200 kg

Guidance: Acoustic, active, range approx 600 metres with favourable inclination of the target submarine. Type AS3T

Firing: Contact (inertial) and proximity (acoustic)

Target: Submarine from 0 to 20 knots and up to 300 metres depth

STATUS:
Quantity production. The equipment is in service with the French Forces.
MANUFACTURERS:
CIT-ALCATEL, Division Marine, 33 rue Emeriau, 75725-Paris CEDEX 15, France.
Programme Direction – DTCN, 2 rue Royale, 75-Paris 8e.

2096.441
L4 AIRBORNE ACOUSTIC TORPEDO

This torpedo is designed to be launched from aircraft or from the ASW missile Malafon (**1179.241**). It is suitable for attacking submarines navigating under water at speeds below 20 knots.

DESCRIPTION:
Conventionally-shaped torpedo having a body made of removable sections of moulded magnesium alloy and comprising the following main compartments:

(1) head section containing the guidance system, the acoustic firing circuits and the warhead (which is contained in a removable canister) with its inertial percussive firing mechanism;
(2) centre section containing the battery and priming elements;
(3) tail section containing the air reservoir, the propulsion unit (electric motor driving two contra-rotating propellers through a reduction gear) and the steering mechanisms.

In addition there are the launching devices designed to insert the torpedo smoothly into the water. These comprise a parachute and release mechanism aft and an ejection cap forward.

OPERATION:
Once in the water the torpedo describes a circular path until its detection mechanisms locate the target; after which it changes course and homes on the target. On reaching its target the warhead is detonated either by the acoustic proximity mechanism or on impact.

CHARACTERISTICS:
Length: 3.13 m including parachute
Diameter: 533 mm
Weight: 540 kg
Speed: 30 knots
Guidance: Active acoustic homing
Target: Submerged submarine at up to 20 knots

STATUS:
In service with the French Navy.
SOURCE:
Direction Technique des Constructions Navales, 2 rue Royale, Paris-8e.

2128.441
L5 MULTI-PURPOSE TORPEDO

DESCRIPTION:
Most recent of the 'L' series of torpedoes the L5 is now operational in the French Navy.

There are two models of the torpedo, the lighter L5 Mod 1 (1,000 kg) being intended for use by surface vessels and the heavier L5 Mod 3 (1,300 kg) being for submarine launch. Both models are of 533 mm calibre and have a speed of 35 knots.

Both models are fitted with a Thomson-CSF active/passive homing head. This has four operating models – direct attack or programmed search with either of the two homing techniques.

MANUFACTURER:
Programme Direction – DTCN, 2 rue Royale, 75-Paris 8e.

2146.441
Z16 SUBMARINE-LAUNCHED TORPEDO

DESCRIPTION:
This is a large submarine-launched anti-ship torpedo. Its main operational features are a programmed sinuous course and remote depth control. The sinuous track makes it difficult for the target to take evasive action even if the torpedo approach is detected.

CHARACTERISTICS:
Length: 7.2 m
Diameter: 550 mm
Explosive charge: 300 kg
Firing: Magnetic proximity or contact

GERMANY (FEDERAL REPUBLIC)

2000.441
SST4 WIRE-GUIDED TORPEDO

DESCRIPTION:
This torpedo is believed to be known also as the Seal and is a 21-inch anti-shipping weapon developed in Germany during the 1960s to replace the older, unguided 21-inch torpedoes then in use.

First fitted (retrospectively) on the *Zobel*-class fast patrol boats (after trials on the earlier *Seeschwalbe*) and subsequently specified also for the Type 143 guided-missile gunboats, the SST-4 mountings are in each case a pair of launch tubes which fire their weapons nose-first over the stern.

Primarily designed to engage surface vessels, the torpedo can also be used against submarines close to the surface but has no deep-dive capability. Torpedo fire control on the type 143 gunboat is by the AGIS (Automatisierte Gefechts und Informations-system Schnellboote) tactical data system in conjunction with the HSA M27 system track-while-scan radar (see **1259.281** and **1590.253**). An important feature of this system when used in conjunction with the SST-4 torpedo is the use of the wire link between the torpedo and the launch vessel to relay data from the torpedo's sonar back to the tactical data system.

STATUS:
Operational in at least the West German navy.
MANUFACTURERS:
Believed to be the AEG Shipbuilding Division in Wedel and Krupp Atlas Elektronik GmbH in Bremen, West Germany.

2178.441
SEESCHLANGE (SEA SERPENT) TORPEDO

DESCRIPTION:
It is understood that two wire-guided torpedoes have been developed in recent years under the direction of the Bundesant für Wehrtechnik und Beschaffung. The two torpedoes were known as the Seal and the Sea Serpent, the former being for use against surface ships and the latter being a deep-diving weapon for use against submarines.

No details of performance are available; but both torpedoes are believed to have been of 21-inch (533 mm) calibre and it is believed that the "Seal" version is the torpedo also known as the SST-4 (**2000.441**).

STATUS:
The SST-4 is certainly operational and it is assumed, but not definitely known, that the Sea Serpent is also.
MANUFACTURERS:
It is understood that the development emerged from a co-operative programme between the AEG Shipbuilding Division in Wedel and Krupp Atlas Elektronik GmbH in Bremen, West Germany.

ITALY

2001.441
SUBMARINE-LAUNCHED TORPEDO TYPE G6e

DESCRIPTION:
This submarine-launched 21-inch (533 mm) torpedo is designed for use against surface vessels or snorkeling submarines.

Main features are acoustic homing and depth preset by NATO 'A' cable. Length is 6 metres.

STATUS:
Operational.
MANUFACTURER:
Whitehead – Moto Fides SpA, Via S. Orlando 10, 57100 Livorno.

2002.441
SUBMARINE-LAUNCHED TORPEDO TYPE G62ef ('Kangaroo')

DESCRIPTION:
This system comprises an unarmed 21-inch (533 mm) wire-guided transport torpedo containing a Mk 44 lightweight 12¾-inch (324 mm) torpedo. Its purpose is to enable the small torpedo to be launched from one submarine to attack another submarine.

The Mk 44 torpedo is built by Whitehead-Moto Fides in Italy under licence from the US Navy. It is believed to be identical in design to the American original (**2820.441**) and is an acoustic homing weapon which is normally launched from surface vessels or from the air.

The G62ef torpedo is 6.2 metres long and carries its 2.573 metre-long burden in what would otherwise be the warhead compartment. Depth is preset by NATO 'A' cable.

STATUS:
Operational.
MANUFACTURER:
Whitehead – Moto Fides SpA, Via S. Orlando 10, 57100 Livorno.

2003.441
SUBMARINE- OR SURFACE-LAUNCHED TORPEDO TYPE A.184

DESCRIPTION:
This new torpedo is currently in development and is presumably intended to replace the G6e weapon (**2001.441**). Wire-guided, it is a 21-inch (533 mm) weapon which can be launched from either submarine or surface vessels against either kind of vessel. It is equipped with an automatic acoustic homing system. Length is 6 metres – the same as the G6e.
STATUS:
Development.
MANUFACTURER:
Whitehead – Moto Fides SpA, Via S. Orlando 10, 57100 Livorno.

2004.441
SURFACE- OR AIR-LAUNCHED LIGHT-WEIGHT TORPEDO TYPE A.244
DESCRIPTION:
This is a small torpedo of the same diameter as, and only slightly longer than the American Mk 44 (**2820.441**) and it appears that it is intended to replace the Mk 44 (currently built in Italy under licence) in Italian service at least.
Not much information on its characteristics is available; but it is clearly a sophisticated anti-submarine weapon, incorporating acoustic homing and having shallow water capabilities, anti-reverberation and CCM characteristics. It is intended to be launched by surface vessels, helicopters, ASROC and aircraft – and presumably also by the G62ef torpedo or a successor (see **2002.441**). Length is 2.7 metres and diameter 12¾ inches (324 mm).
STATUS:
Development.
MANUFACTURER:
Whitehead – Moto Fides SpA, Via S. Orlando 10, 57100 Livorno.

SWEDEN

2323.441
TORPEDO TYPE 41

DESCRIPTION:
Torpedo Type 41 is a small active homing weapon designed to operate in shallow water or under other acoustically difficult conditions. Its homing sonar operates to give both azimuth and depth guidance and the torpedo can be used against both surface targets and submarines. Propulsion is electrical.
The torpedo is 2.5 metres long, has a diameter of 400 mm and weighs 250 kg. It can be launched from surface vessels or submarines.
Both impact and proximity fuses are fitted.
The torpedo is easily maintained and can be used in conjunction with simple fire control equipment. It is therefore suitable as armament for almost any kind of vessel – even fishing boats.
STATUS:
Type 41 was extensively tested before adoption by the Royal Swedish Navy with which it has been in service for several years. A further development programme is in hand: this is aimed at producing a torpedo with the same external dimensions but suitable for launching from helicopters as well as from surface vessels and submarines.
MANUFACTURER:
Förenade Fabriksverken, S-631 87 Eskilstuna 1, Sweden.

2367.441
TORPEDO TP 61

DESCRIPTION:
Torpedo Type 61 is a 21-inch (533 mm) wire-guided weapon carrying a 250 kg explosive charge. Designed for use against surface targets, it can be launched from either surface vessels or submarines and can readily be adapted to fit a variety of launch tubes.
Hydrogen peroxide is used as an oxidiser, and it is said that this gives a run about three times as long as that of a conventional torpedo travelling at the same speed.
Maintenance requirements are low: storage time without overhaul is 10 years with only routine checks each year, and the torpedo will remain operational in its tube for up to 4 months without overhaul.
STATUS:
The torpedo has been produced in large numbers for the Royal Swedish Navy and has been supplied to some NATO countries, including, it is believed, Denmark and Norway. Extensive firing trials have established its reliability in a variety of conditions.
MANUFACTURER:
Förenade Fabriksverken, S-631 87 Eskilstuna 1, Sweden.

THE UNITED KINGDOM

2552.441
TORPEDO MARK 8

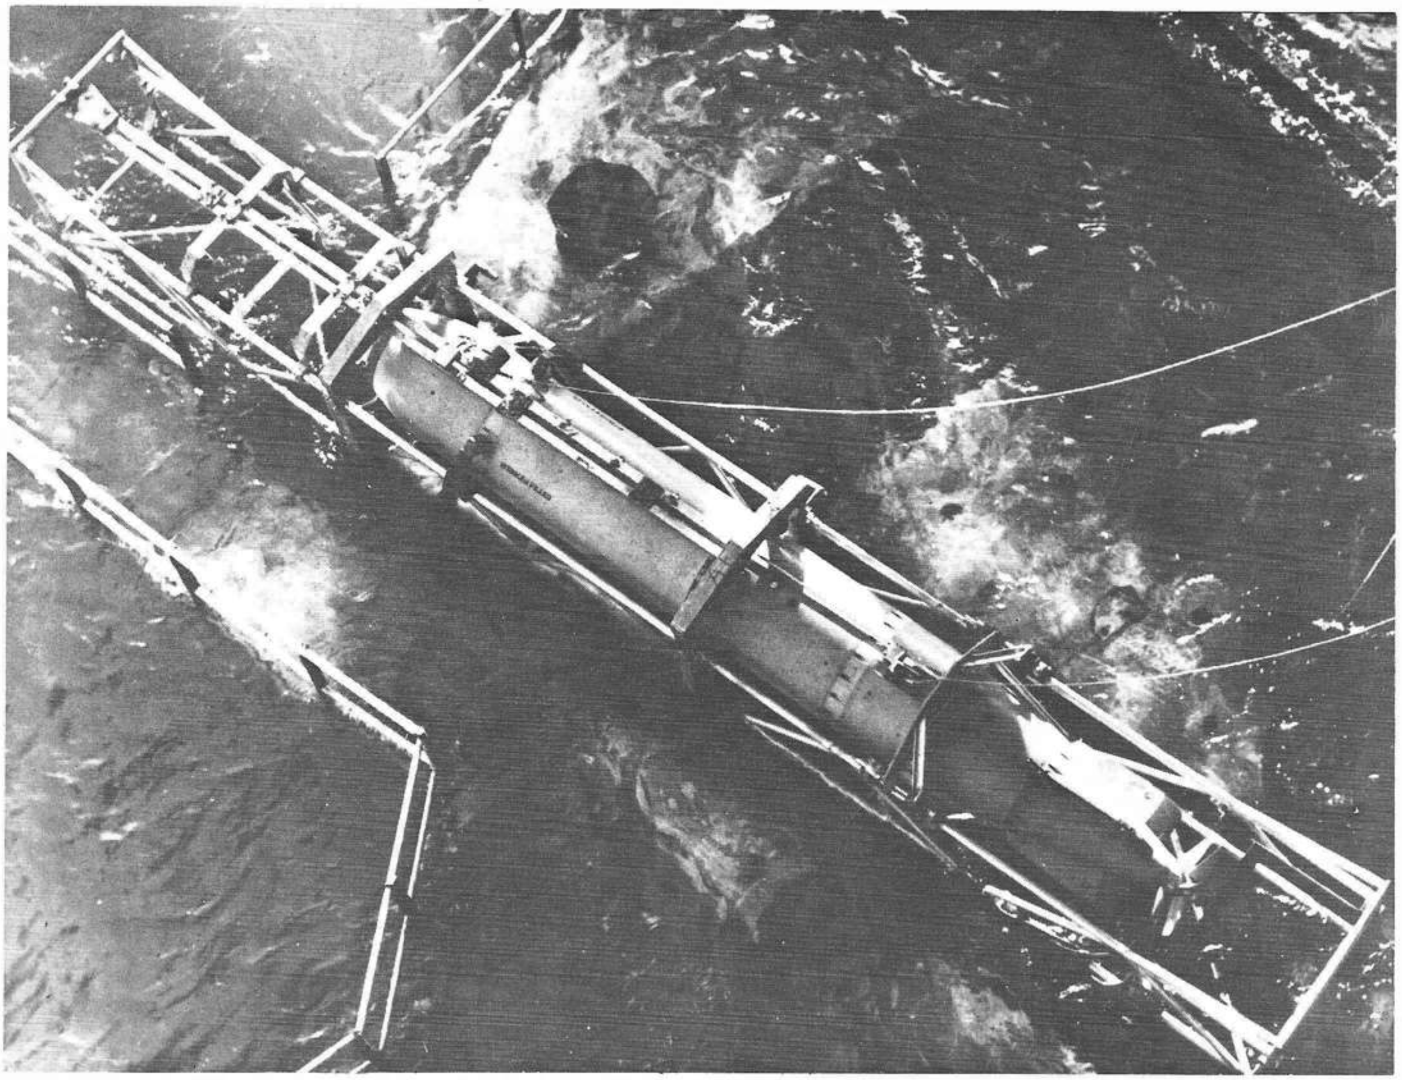
DESCRIPTION:
Quite possibly the longest-lived of all torpedo designs and certainly a remarkable survival in an otherwise reasonably sophisticated navy, the Mark 8 torpedo, which was designed in the early to mid-1930s, was certainly in service in the Royal Navy – including nuclear-powered submarines – until 1973, may possibly still be in service with some minor vessels and is almost certain to be found in some other navies.
Like the American Mark 14 (**2813.441**) the Mark 8 is a 21-inch (533 mm), compressed-air-driven, free-running weapon. Although it can scarcely be regarded as reasonable that so unsophisticated a device should continue to be the primary armament of the principal attack submarines of the Royal Navy; it should perhaps in justice be said that, within its limitations, it has performed well and given service which is honourable as well as long.
STATUS:
Obsolescent. Being replaced in RN service by the Tigerfish torpedo (**2440.441**).

2448.441
TORPEDO PROJECT 7511
DESCRIPTION:
This project covers the development of a new lightweight torpedo for use on surface ships or by helicopters or other aircraft.
The project is on the one hand a replacement for the Mark 31 project (**2473.441** 1971-72), which has been cancelled, and on the other hand aimed at providing a torpedo which the Royal Navy can use in place of the American Mark 46 (**2822.441**). The Mark 31 project, which was cancelled after about five years, was aimed at providing a replacement for the American Mark 44 (**2820.441**) which was the forerunner of the Mark 46.
STATUS:
Believed to be in study phase.
MANUFACTURER:
Marconi Space and Defence Systems Ltd, Marconi House, Chelmsford, Essex, England.

2471.441
TORPEDO MARK 20 (IMPROVED)
DESCRIPTION:
To meet the need for an inexpensive torpedo compatible with modern control systems Vickers has updated the Mk 20 torpedo.
The Mk 20 is a silent running, electrically-driven anti-submarine sonar homing torpedo of proven reliability. The improved version aims at providing a cost-effective alternative to existing torpedoes and in addition, when used in conjunction with the Oberon-class submarines, extends the submarine's attack capability, since fire control parameters can be updated to the moment of firing, even from the submarine's counter-measure tubes.
To bring the Mk 20 torpedo into line with modern submarine weapon control systems, light-weight synchro-mechanisms have been fitted which enable the depth and course angles to be set using a standard NATO 'A' link (umbilical cable).
Careful consideration was given throughout the modification to ensure that the total weight of the weapon and its dynamic characteristics remained unchanged: and calculations and tests have shown that the hydrodynamic and operational performances remain identical to those of the Admiralty standard torpedo.
CHARACTERISTICS:
Length: 4.11 m
Diameter: 21 in (533 mm)
Weight: Practice – approx 746 kg. Warshot – approx 821 kg
Buoyancy: Practice – approx 18 kg positive. Warshot – approx 61 kg negative
Range: Warshot – 11,000 m at 20 kt
Battery: Practice – Lead-acid. Warshot – Perchloric acid
Homing: Passive sonar (depth and azimuth)
Warhead: 91 kg. Torpex contact pistol
Function: Anti-submarine with limited anti-ship capability
Running Depth: 3-64 m
Max Homing Depth: 244 m
Turning Circle: 64 m diameter
STATUS:
In December 1970, successful trials were carried out on the improved torpedoes and final discharge trials from a submarine at sea were concluded during 1971.
Torpedoes are held in unmodified form by the

UK Ministry of Defence and are available only on a government-to-government basis.

MANUFACTURER:
Vickers Ltd, Barrow Shipbuilding Works, Barrow-in-Furness, England.



Improved Mark 20 torpedo loaded in launching cradle for test firing

2440.441
TORPEDO "TIGERFISH"

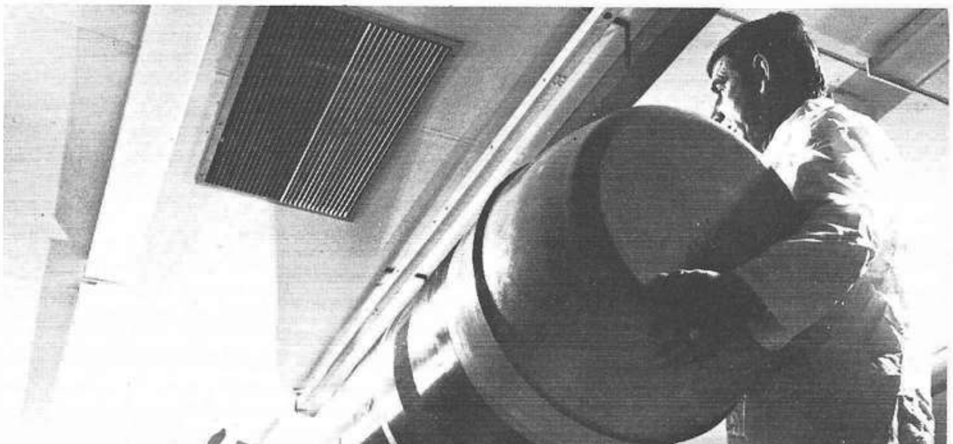
DESCRIPTION:

Tigerfish is the name given to the production weapon derived from a redevelopment of the Mk 24 torpedo (**2472.441** 1972-73). The weapon is a 21-inch wire-guided/acoustic homing torpedo fitted with impact and proximity fuses and is designed for submarine launch.

Wire guidance is used in the initial stages of an engagement up to the point where the torpedo's active/passive acoustic homing system can control the run in to the target. Wire is dispensed from both torpedo and submarine so as to avoid any wire stress due to their relative motion. The torpedo is roll-stabilised by controlling ailerons on retractable mid-body stub wings and is steered by hydraulically powered cruciform control surfaces mounted at the tail.

The torpedo carries its own computer which is connected through the guidance wires to the computer of the submarine's torpedo fire control system. During the wire guidance phase the on-board computer responds to the demands of the submarine computer; and on the homing run it interprets the data from the homing system sensors and calculates and commands the appropriate course, subject to a priority overriding steer-off azimuth control from the submarine.

During a homing run using the torpedo's active sonar the interrogation rate is progressively increased, as the torpedo nears the target, so as to improve system accuracy. The interrogation rate is controlled by the on-board computer – which is thus performing several functions during this phase: interrogation control, sonar data computation, torpedo steering control and data transmis-



Tigerfish torpedo

sion to the submarine to update its own computer memory.

CHARACTERISTICS:
Length: 6.464 m
Diameter: 21 inches (533 mm)
Weight: 1,550 kg (in air)
Speed: Dual high / low selectable at all times
Fuse: Impact and proximity
Propulsion: Electrically driven contra-rotating propellers

STATUS:
In production for the Royal Navy. Data given above relate to the warshot torpedo: there are also exercise and dummy (handling) versions. The exercise version is similar to the warshot but has rechargeable batteries, becomes buoyant at the end of the run and has an instrumentation pack for data analysis in place of the warhead.

Possibilities of system improvement are being studied.

MANUFACTURERS:
Marconi Space and Defence Systems Ltd, Marconi House, Chelmsford, Essex – main contractor.
Major sub-contractor – The Plessey Company Ltd, Ilford, Essex.

2491.441
DRILL & PRACTICE TORPEDO MW 30 (MARK 44)

DESCRIPTION:
The Anti-submarine Drill and Practice Torpedo MW 30 is designed to provide practice in the handling, loading, arming and release of Mark 44 torpedoes (**2820.441**).

The drill round has the same dimensions and centre of gravity as the warshot weapon and is fitted with the same external attachments and controls – such as the arming pin and seawater scoop and the umbilical socket – as the Mark 44. It will withstand an external pressure of 6.8 atmospheres and will withstand shock accelerations (with a maximum duration of 8 milliseconds) of 40 g aft 120 g forward and 50 g laterally; so that it can be used for practice launches from a variety of launchers. Shortly after entering the water it floats on the surface. For airborne launches there is provision for the recording of airborne presetter settings.

Operational life is designed to be a minimum of 150 launchings and the operational temperature range is −18° to +70°C. Storage temperature limits are −45° and +70°C and the round has a storage life of 15 months between inspections.

STATUS:
In service.

MANUFACTURER:
Plessey Marine, Uppark Drive, Ilford, Essex, England.

Plessey MW 30 drill and practice torpedo

THE UNITED STATES OF AMERICA

2813.441
TORPEDO MARK 14

DESCRIPTION:
Torpedo Mark 14 is a 21-inch (533 mm), submarine-launched, compressed-air-driven weapon which first went into service in the US Navy in 1935. It is 5.25 metres long and weighs 1,780 kg.

Some serious problems were encountered when the torpedo came to be used in earnest during the Second World War. The torpedo has both influence and contact fuses; and it was found that the former was so liable to premature detonation that it had to be disconnected before launch while the contact fuse was liable to failure. The depth-control gear was also unreliable and frequently caused the torpedo to run too deep.

An urgent programme corrected these faults, however, and the torpedo continues in service to this day with the US Navy and elsewhere.

STATUS:
Operational.

2814.441
TORPEDO MARK 16

DESCRIPTION:
Torpedo Mark 16 is a 21-inch (533 mm) torpedo designed as a successor to the Mark 14 but which in the event has been used in parallel with it throughout its period of service in the US Navy. It is 6.25 metres long, weighs 2,180 kg and carries a 400 kg explosive charge. Propulsion is by a fuel / hydrogen peroxide thermal engine.

STATUS:
The Mark 16 torpedo was withdrawn from US Navy service in 1973 but may still be in use elsewhere.

2815.441
TORPEDO MARK 18

DESCRIPTION:
Developed during the Second World War, the Mark 18 weapon was designed by Westinghouse using a captured German torpedo as a starting point. Propulsion was electric.

More than 8,500 of these torpedoes were built for use in the Second World War and the Korean conflict. The weapon is no longer in production but some survivors may still exist.

2831.441
TORPEDO MARK 27

DESCRIPTION:
Torpedo Mark 27 was an electrically-propelled, free-running weapon with passive sonar homing. Designed as a dual-purpose weapon it was used by the US Navy as a means of obtaining tactical experience in training exercises prior to the introduction of the Mark 37 Mod 0 torpedo (**2817.441**). Available data on Mk 27 relates to Mod 4.

Like its Mk 37 successor, the Mk 27 had a diameter of 19 inches (482.6 mm); its length was 3.23 metres. Although it was primarily used as a training device by the US Navy some production torpedoes were fitted with warheads and sold overseas.

STATUS:
No longer in US Navy service. Possibly still in service elsewhere.

2816.441
TORPEDO MARK 28

DESCRIPTION:
This weapon was developed by Westinghouse during the Second World War and more than 2,000 were produced. It is no longer in production.

Successor to a number of weapons of which only development quantities were built (notably the Marks 19, 21, 22 and 26) the Mark 28 was an all-electric 533 mm-calibre weapon, 6.25 metres long. It used passive acoustics and pattern running for terminal homing.

STATUS:
Not definitely known, but believed to be no longer in USN service.

2817.441
TORPEDO MARK 37 MODS 0 AND 3

DESCRIPTION:

Designed primarily as a submarine-launched anti-submarine torpedo, but suitable for deck launching by the Mark 23 and Mark 25 torpedo launchers, the Mark 37 torpedo is a 19-inch (482.6 mm) weapon that has been described as the first successful high-performance anti-submarine torpedo. The 19-inch diameter of all versions of this torpedo was chosen to enable the torpedo to swim out from a standard 21-inch launch tube – an arrangement with obvious operational advantages.

Of the four reported versions of this torpedo Mods 0 and 3 feature active and passive terminal homing. The weapon is an all-electric dual-speed device 3.52 metres long and weighing 648 kg (warshot) or 540 kg (practice).

Mod 3 is an updated version of Mod 0, the updating consisting of the incorporation of a large number of minor modifications.

DEVELOPMENT:

Developed by Westinghouse the Mark 37 Mod 0 torpedo first went into service in 1957. Mark 37 torpedoes have been produced in large quantities by the Naval Ordnance Plant, Forest Park, Illinois, and are still in widespread use in the US Fleet.

STATUS:

Operational, but replacement by the Mark 48 torpedo (**2823.441**) has now begun.

2818.441
TORPEDO MARK 37 MODS 1 AND 2

DESCRIPTION:

These versions of the Mark 37 torpedo differ from Mods 0 and 3 (**2817.441**) in their size and method of guidance; in other respects they are substantially similar.

Both versions are wire guided, whereas the Mark 37 Mods 0 and 3 are free-running torpedoes. Both are 4.09 metres long and weigh 766 kg (warshot) or 657 kg (practice).

Just as Mod 3 is an updated version of Mod 0 so is Mod 2 a version of Mod 1 updated by the incorporation of a number of minor modifications.

STATUS:

Operational.

2830.441
TORPEDO MARK 37 CONVERSION (TORPEDO 37C)

DESCRIPTION:

Torpedo 37C is available in two types which are conversions of the wire-guided Torpedo Mk 37 Mod 2 (**2818.441**) and the non-wire-guided Mk 37 Mod 3 (**2817.441**). In each case the modification is carried out using a conversion kit developed by Northrop Corporation to improve the speed, range and acoustic capability of the torpedo.

The conversion kit is designed for user installation and incorporates an Otto fuel engine which replaces the electric motor and batteries. This replacement propulsion system increases the torpedo's maximum speed by more than 40% and nearly doubles its range. These improvements, together with a substantial increase in acoustic capability bring the torpedo into line with weapons of more recent design at moderate cost.

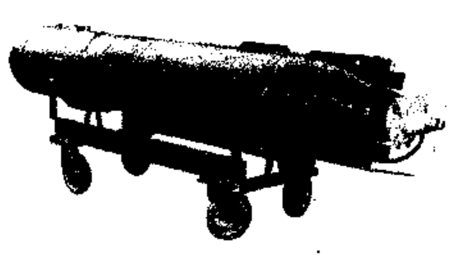
Whereas the Mark 37 torpedo was designed as an anti-submarine weapon, the 37C can be used also against surface vessels. The modification kit thus considerably extends the usefulness of the weapon; and it includes such operational improvements as re-attack logic, shallow water capability and the ability to attack slow or stationary targets.

STATUS:

In production and entering service in the Canadian Armed Forces and the Royal Netherlands Navy.

MANUFACTURER:

Northrop Corporation.



Northrop Torpedo 37c

2819.441
TORPEDO MARK 43

DESCRIPTION:

Two models of this torpedo have been produced, one (Mod 1) for launching from either fixed-wing aircraft or helicopters, the other (Mod 2) for launching from helicopters only. The latter is now regarded as obsolete.

Torpedo Mark 43 is a 10-inch (254 mm) weapon 2.35 metres long and weighing 120 kg. It is electrically propelled.

2820.441
TORPEDO MARK 44

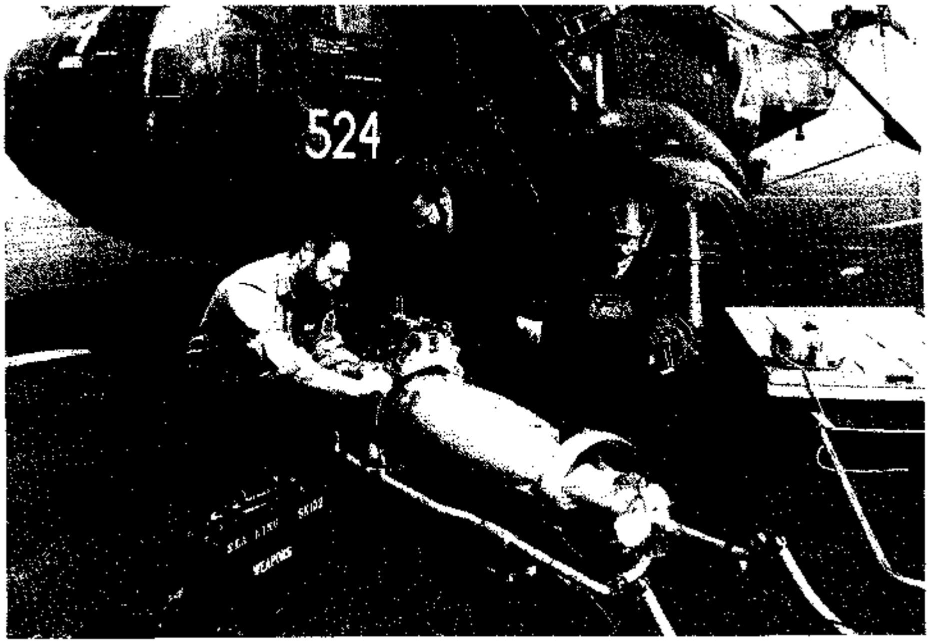
DESCRIPTION:

This is a lightweight torpedo designed for launching from aircraft or helicopters, from surface vessels (using Mk 32 tubes) or by the ASROC rocket system (**6001.241**).

Two models have so far been produced but the differences in dimensions are trivial. Both torpedoes are electrically propelled and their calibre is 12.75-inch (324 mm). Approximate length is 2.56 metres and the torpedoes weigh about 233 kg. Active acoustic homing is used. Depth and course settings are entered by umbilical cable. Arming is by seawater scoop.

STATUS:

Mark 46 (**2822.441**) is the replacement for the Mark 44 in USN service but the Mark 44 continues in service in other countries – notably the UK.



Mark 44 torpedo being prepared for loading on a Sea King helicopter

2821.441
TORPEDO MARK 45 (ASTOR)

DESCRIPTION:

This 19-inch (483 mm) anti-submarine torpedo (ASTOR stands for Anti-Submarine Torpedo Ordnance Rocket) is a high-speed long-range weapon and it is capable of carrying a nuclear warhead. It first went into service around 1960.

Intended for use by nuclear-powered or modernised diesel-electric submarines the Mark 45 torpedo is approximately 5.76 metres long and weighs about 1,310 kg. It has a high maximum speed and can submerge deeply without damage. Although designed primarily for use as a wire-guided ASW weapon it can also be used against surface targets. Maximum range is in excess of 16 km.

MANUFACTURER:

Westinghouse Systems and Technology Divisions, Baltimore, Maryland, USA.

2822.441
TORPEDO MARK 46

DESCRIPTION:

Torpedo Mark 46 is a lightweight, 324 mm calibre weapon designed, as a successor to the Mark 44 (**2820.441**), for use with several ASW systems. It can be launched from surface vessels, fixed-wing aircraft or helicopters and can be carried by the ASROC rocket (**6001.241**). Mk 32 tubes are used for surface launching.

The torpedo was the first of the weapons which emerged from the RETORC (Research Torpedo Configuration) programmes – specifically the RETORC I programme carried out by the US Naval Undersea Centre (NUC) Pasadena Laboratory with industrial assistance. USN handling of the transition from this research programme to industrial development has been criticised on the grounds that the transfer took place a year too soon – so that concept formulation and contact definition phases were skimped – and that an arbitrary reduction of a year in the planned industrial development programme was imposed on the contractor. The problems resulting from these actions were satisfactorily resolved in the end, however, and the Mk 46 torpedo is a current operational weapon in US Navy service.

The Mk 46 is a deep-diving, high-speed torpedo fitted with an active/passive acoustic homing system and intended for use against submarines. After water entry it searches for, acquires and attacks its target: if it misses the target it is capable of multiple re-attacks.

Two models of the Mk 46 have been produced. Mod 0 was the first US torpedo to be powered by a solid-fuel motor: it is 2.67 metres long and weighs about 258 kg. Mod 1 is slightly lighter and is powered by a liquid mono-propellant (Otto) motor.

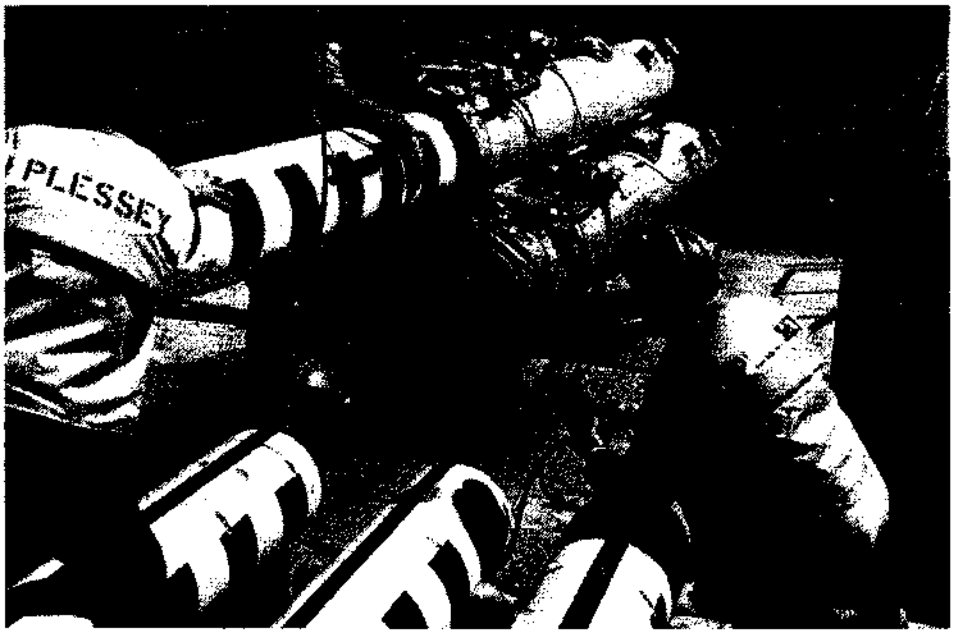
STATUS:

Operational. The first delivery to the US Navy was made on 28th October, 1965. Following the cancellation of the Mk 31 torpedo a quantity of Mk 46 torpedoes was purchased as an interim measure by the UK Ministry of Defence for Royal Navy use.

MANUFACTURERS:

Aerojet-General Corporation, Azusa, California, USA were responsible for the development and early production of both Mod 0 and Mod 1.

Honeywell Inc and Clevite Corporation have also been involved in manufacture.



Triple trainable Mk 32 torpedo launcher being loaded with Plessey MW 30 drill torpedoes

2541.441
CAPTOR – ENCAPSULATED TORPEDO

DESCRIPTION:

Captor – a contraction of "encapsulated torpedo" is the name given to an anti-submarine system comprising a Mark 46 torpedo (**2822.441**) inserted into a mine casing.

The mine/torpedo system can be laid in deep water and is suitable for air-dropping from, for example, B-52 bombers. It is understood that the operational plan involves sowing the mines in narrow seas – e.g. those between Greenland, Iceland and Great Britain – to attack and destroy enemy submarines as they attempt to pass through on their way to or from their operational stations. If desired, the torpedo could be fitted with a nuclear warhead.

It is understood that the system is equipped with means of discriminating between submarines and surface vessels: it may be surmised also that there is some technique whereby a friendly submarine (or other vessel) can inhibit the torpedo release mechanism.

STATUS:

Following an eight-year development programme costing some $100 million, Captor is now scheduled to enter service in mid-1975.

MANUFACTURER:

Goodyear Aerospace Corporation, 1210 Massillon Road, Akron, Ohio 44315, USA.

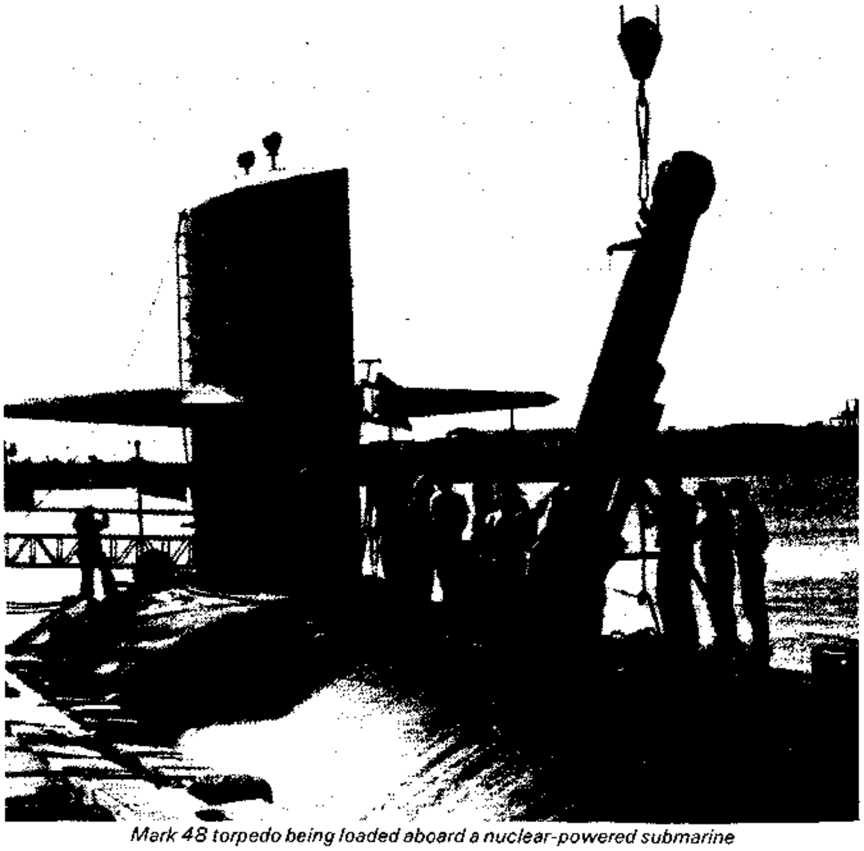
2823.441
TORPEDO MARK 48

DESCRIPTION:

Torpedo Mk 48 is a highly-sophisticated 21-inch (533 mm) submarine-launched anti-submarine and anti-ship weapon which has been described – possibly correctly – as the most complex torpedo ever designed.

Like the Mk 46 torpedo (**2822.441**) the Mk 48 is a result of the RETORC (Research Torpedo Configuration) programmes. RETORC II, the programme which resulted in the Mk 48, was carried out by the Applied Research Laboratory (formerly the Ordnance Research Laboratory), by Pennsylvania State University and by the Naval Underwater Systems Centre at Newport, R.I. This programme was initiated in November 1956; development characteristics were established by December 1960; and by May 1962 the development was put out to tender, the torpedo then being described as the EX-10. As a result of this competition it was decided to proceed with two significantly different competing designs, and contract definition contracts were awarded to Westinghouse Electric Corporation and Clevite Corporation (now Ocean Systems Division, Gould Inc). On the results of these contracts Westinghouse was awarded a contract to develop and produce prototypes of Mk 48 Mod 0 and a back-up programme for a different acoustic system was covered by a contract awarded to Clevite in 1964.

Mod 0 was an ASW-only system; but in 1967-68 it was decided that an anti-surface ship capability was needed as well. Contracts were accordingly awarded to Westinghouse for the



Mark 48 torpedo being loaded aboard a nuclear-powered submarine development of a Mod 2 version and to Clevite for the development of the Mk 48 Mod 1. Both developments were taken to the pilot production stage – pilot production being authorised in 1970 – and it was not until 1971 that a decision was taken to adopt the Mod 1 for service use. A production contract was awarded to Gould (ex-Clevite) on 2nd July, 1971.

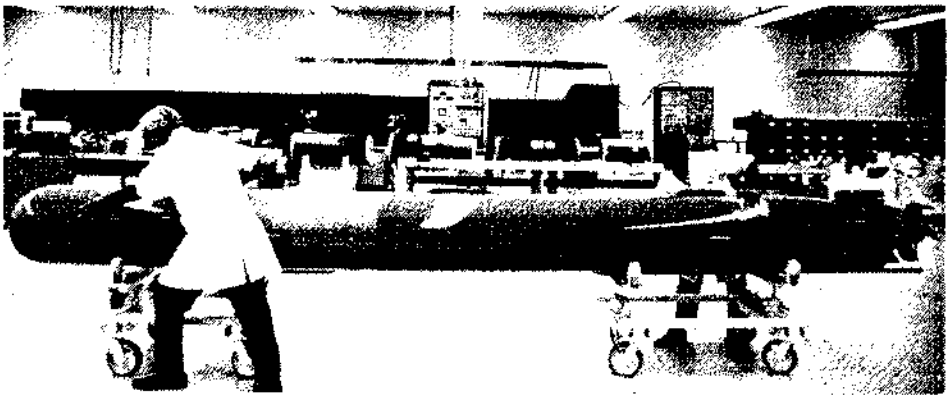
The chosen Mod 1 torpedo is a high-speed, long-range, deep-diving weapon which can be operated with or without wire command guidance and can use active and/or passive acoustic homing. Like the Mk 46 torpedo, after entering the water it executes a target search, acquisition and attack procedure and is capable of multiple re-attacks if it misses the target, but has the added facility of wire guidance if required. Propulsion is by means of a piston-type swash-plate engine powered by hot gas and driving a pump jet propulsor.

CHARACTERISTICS:
Length: 5.8 m
Diameter: 21 in (533 mm)
Weight: about 1,600 kg
Max speed: 93 km/h
Max range: 46 km
Max depth: 500 fathoms (914 m)
STATUS:
Operational in US Navy since early 1972. Will be primary armament on the new SSN-688 nuclear-powered hunter-killer submarines. Approximately 500 Mod 1 torpedoes were produced in FY 1974 and a similar quantity is planned for 1975. This is expected to satisfy the urgent needs of the USN. An attempt by the British Government to purchase a quantity of Mk 48 torpedoes in 1971/72, to tide the Royal Navy over the gap caused by the delay in the Mk 24 programme, was unsuccessful as all available torpedoes were required by the USN.
MANUFACTURER:
Gould Inc. Ocean Systems Division, Cleveland, Ohio, USA.

2618.441
FREEDOM TORPEDO
DESCRIPTION:
Developed by Westinghouse as a private venture, but with the benefit of their long experience in designing torpedoes for the US Navy and incorporating many components that are common to Navy torpedoes, the Freedom Torpedo is a full-size weapon with a large warhead which is intended for use against surface shipping.

Basically a 19-inch (483 mm) weapon it is used with 21-inch (533 mm) tubes, and it is suitable for either deck-launching or submarine launching. It is compatible with a wide range of fire control systems and can be launched from fast torpedo boats or destroyers. A contact detonator is used and arming is dependent on distance travelled; there is also an anti-circular run protection device. The torpedo is powered by a seawater battery.

Two models are available. Mod 0 is wire-guided with programmed terminal patterns. Mod 1 is wire-guided and fitted with a long-range homing system.



Freedom Torpedo

CHARACTERISTICS:
Length: 572 cm
Diameter: 48.3 cm. With runners for 21-inch tubes
Weight: Warshot, 1,237 kg. Exercise 950 kg
Speed (electric propulsion): 40 knots
Range: 10,900 m
Battery (seawater): 9-minute life
Launch:
Surface: Deck or rack
Submarine: Tube
Launch Modes: Impulse or swim out
Depth at Impact: Can be set between 2 and 15 metres
Explosive Charge: 295 kg minimum
Buoyancy: Warshot, Negative; Exercise, Positive
MANUFACTURER:
Westinghouse Defence and Electronic Systems Centre, Balitmore, Maryland, USA.

2793.441
NEW TORPEDO PROJECTS

DESCRIPTION:
According to American press reports the US Navy is in process of developing a new deep-diving torpedo known as DEXTOR – acronym for Deep Experimental Torpedo – and intended ultimately for use against deep submerging nuclear-powered submarines.

Another report states that a new lightweight torpedo is to be developed for introduction into US Navy service in the 1980s.

No details of either project have been received but the report concerning DEXTOR has stated that Honeywell will be the principal contractor for the programme.
STATUS:
Project.
MANUFACTURER
Believed to be Honeywell Inc.

THE UNION OF SOVIET SOCIALIST REPUBLICS

2995.441
533 mm TORPEDO
DESCRIPTION:
Certainly until recently, and possibly on a continuing basis, the standard calibre of torpedo in service in the Russian Navy has been 533 mm weapons. A torpedo of smaller calibre was in use on torpedo boats and escort vessels before the Second World War, but this is now to be found only on P-4-class patrol boats.

It may confidently be assumed that torpedo development in the USSR has generally proceeded along lines similar to those of developments in Britain, France and the USA and has probably taken the form of development from wartime German pattern-running and homing torpedoes.

It is, however, worth noting that somewhere around the late 1950s a version of this torpedo with a nuclear warhead was deployed in some submarines – probably the F and N classes. Although the nuclear torpedo is almost certainly a very much less significant weapon in Russian eyes now than it was then, there are probably several still in service.

Two distinct stages have been distinguished in the development of surface vessel launchers for torpedoes of this calibre; and the fact that the launchers are of slightly different lengths at these two stages may indicate that the corresponding torpedoes are also different – but it does not necessarily do so.

The dates of introduction of these two launcher groups appear to have been about 1948/49 and 1957/58. Apart from the difference in length just mentioned the principal change appears to be from manual local training to remote power training. 1-, 3- and 5-tube launchers are found in the earlier series; 2-, 3-, 4- and 5-tube launchers in the later.
STATUS:
All the above types of launcher seem still to be in service, as also, presumably are the torpedoes. 533 mm torpedoes are also a standard weapon on Russian submarines; but the use of 406 mm weapons (**2997.441**) has also been reported.

2996.441
AIRBORNE TORPEDO
A torpedo smaller than the standard 533 mm weapon is used by the Russian Naval Air Forces. It is thought possible that this is a development of the pre-war 18-inch calibre weapon, but no details are known.

2997.441
LIGHT TORPEDO
Of comparatively recent development a 406 mm torpedo is now in service with some submarine chasers and light destroyers of the Russian Navy. This is launched from trainable tubes that are only about 5 metres long, so the torpedo must be quite a small one. No other details are available but it should be noted that the use of this calibre of torpedo on submarines has also been reported

UNDERWATER WEAPONS

THE UNITED STATES OF AMERICA

1128.441
SUBROC (UUM-44A) ANTI SUBMARINE MISSILE

DESCRIPTION:

Submarine launched missile which follows a short underwater path before transferring to an air trajectory for the major portion of its journey to the target area. When this is reached, a nuclear depth bomb is separated from the remainder of the missile and then follows a ballistic trajectory to the point where it re-enters the water. The nuclear charge then sinks to a predetermined depth before detonation.

Principal characteristics of Subroc are:- length 625 cm, diameter 53.3 cm, weight 1,853 kg (approx), range 56 km (approx). Speed 'supersonic'. Solid-fuel motor.

OPERATION:

The UUM-44A missile forms part of an advanced anti-submarine system designed for deployment in nuclear-powered attack submarines operating against submerged vessels armed with strategic missiles. This system includes the AN/BQQ-2 Raytheon integrated sonar system and the Mk 113 Subroc fire control system produced by the Librascope division of Singer-General Precision Inc.

After detection and location of a target submarine, co-ordinate data is fed into the attack submarine weapon system which programs an optimum mission profile for the Subroc missile. It is assumed that this can be accomplished in virtually 'real-time'.

The Subroc missile is launched horizontally from a standard 21-inch (53.3 cm) torpedo tube, by conventional means. At a safe distance from the launch vessel (which need not be directed toward the target area for firing) the solid-fuel missile motor is ignited and the missile follows a short level path before being directed upward and clear of the water. Missile stability and steering is effected by four jet deflectors, which function in both the water- and air-borne sectors of the trajectory. Guidance is by means of an inertial system (SD-510) produced by Kearfott.

When free of the water, Subroc is accelerated to a supersonic speed and guided toward the target area. At a predetermined point separation of the nuclear depth bomb is initiated by explosive bolts and a thrust-reversal deceleration system which enables the warhead to continue to the re-entry point on a ballistic trajectory controlled by vanes on the depth bomb. The remainder of the missile falls free behind the bomb.

Impact with the water is cushioned to protect the arming and detonation devices. A pre-set depth sensor detonates the nuclear charge when the bomb is in the vicinity of the target.

Subroc missiles can be carried in torpedo tubes without attention for long periods, and launched with minimal preparation time.

DEVELOPMENT:

Development of the UUM-44 began in June 1958 at the US Naval Ordnance Laboratory, White Oak, Maryland, under the management direction of the Bureau of Naval Weapons, with Goodyear Aerospace Corporation as the prime contractor. Technical evaluation was completed in 1964, and production and operational deployment began in 1965.

STATUS:

Subroc is now operational on nuclear-powered attack submarines. Each ship carries four to six Subroc missiles. Production is expected to continue at least until 1978.

MANUFACTURERS:

Goodyear Aerospace Corporation, 1210, Massillon Road, Akron, Ohio 44315, USA Prime contractor.

JINDIVIK

The Jindivik continues to be a standard weapons target in Australia and the United Kingdom. Total value of orders, including associated equipment exceeds $47 million. Total value of export orders exceeds $25 million.

Optional equipment includes:

(1) An airbrake fitted under the rear fuselage, which may be used as a dive brake to reduce descent time from high altitude. Power to activate the airbrake is supplied from the aircraft pneumatic supply. The airbrake may be used to control speed when two Jindiviks are flown in close formation. For this purpose a separate pneumatic supply is provided.
(2) An in flight variable fin tab.
(3) Bolt-on extension wings: 40 inch (103 cm), or 80 inch (206 cm) for extra high altitude.
(4) Wing tip pods: Mk 8 for fuel and optical mis-distance measuring equipment and Mk 5 for MDI equipment only. These pods may be used in conjunction with the extension wings.
(5) Recoverable towed targets employing infra-red or active radar augmentation.

LEADING PARTICULARS:

Power plant: One Bristol Siddeley Viper Mk 201 turbojet engine
Systems: Non-regenerative pneumatic system using air stored in accumulator. Engine driven alternator, 9KVA, 208V, 3-phase 300-550 Hz. 24 VDC battery
Remote control: Aircraft controlled from ground or airborne station
Take-off: Aircraft mounted on trolley from which it lifts off, 305 metre run
Landing: On retractable skid. 457 metre run
Max Payload: 108 kg
Max Diving Speed: 630 kmh standard. 1,040 or 445 kmh for short or extended span
Max Cruising Speed: 910 kmh
Economic Cruising Speed: 250 kmh
Rate of Climb: 4,570 metres/min at S/L
Service ceiling: 18,900 metres standard. 16,760 or 20,100 metres for short or extended span
Range with allowances: 820 km standard. 1,320 km with Mk 7 pods

TONIC TOWED TARGET SYSTEMS:

Tonic is the official name given by the Department of Supply Weapons Research Establishment, to a high speed towed target system designed primarily for use in conjunction with the Jindivik Mk 3 drone, but may be used with other drone aircraft.

The operational capabilities of the system are based upon the philosophy of short tug/tow separations. This enables the tug aircraft to employ cine cameras to record miss-distance information whilst the displacement of the tug from the target is such as to keep it clear of the weapon's anticipated lethal area. The targets are carried on underwing pylons and supported by conventional bomb release units. The winch unit which controls the streaming and recovery of the

Jindivik target drone

target/s is normally mounted in the tug aircraft's fuselage. One or two targets may be streamed to pre-set tug-target separation distances and when commanded by the radio link recovered by the tug.

In the locked-out state the target/s may be towed at speeds up to 450 knots I.A.S. The target/s can be streamed or recovered in straight flight at speeds up to 250 knots I.A.S. The recovery sequence may also be carried out with the tug aircraft descending at a rate not exceeding 4,000 feet per minute. "Stream Port" or "Stream Starboard" radio command signals energise the appropriate release unit and the target separates from the tug aircraft in a nose down attitude, thus adding to its weight a negative lift to assist in pulling wire off the drum. This is opposed by a magnetic brake which increases its torque load as the target approaches its programmed separation distance where it is "locked out" by a plate clutch. On the command "Recover" both the plate clutch and the magnetic brake are de-energised. Simultaneously the winch motor is energised, and the towing wire is wound back on to the drum. In the event of a weapon strike or malfunction, an explosive wire cutter, sited near the winch unit, permits jettison of the towed target/s.

TONIC TARGETS:

The target is a centre of gravity tow and is available in two forms: infra-red augmented (six pyrotechnic flares); or active micro-wave augmentated. Both versions are of the same dimensions and aerodynamic configuration being cylindrical metal bodies of 16 cm diameter with a main plane of 51 cm span and cruciform tails. The overall body length is 122 cm.

Two WRETAR cameras are fitted to the tug aircraft wing pods. They operate together, controlled by the radio link from the ground.

For a tow wire length of 300 feet, the cameras are fitted with lenses of 1-inch focal length. The cameras are accurately aligned to each other and prisms mounted externally on the camera lenses direct the fields of view to contain the target. The field covers a circle of approximately 300-feet diameter at this distance. Timing signals are sent from the ground by radio for time correlation of the two cameras. With the above arrangement, all missiles intercepting the target will appear on at

Tonic Mk 5 radar augmented tow with early type nose-cone. The rotatable latch for offset towing can be seen on top of the body

least three cine frames from each camera. Three is a convenient number for computing the miss-distance, using a modified triangulation method of solution. The cameras can be stopped and restarted so as to record up to three interceptions in one sortie.

STATUS:

Jindivik orders received as at 31 December 1973 stand at 466. The number of Jindiviks delivered to that date number 423, details of orders/deliveries are as follows:

	Ordered	Delivered
United Kingdom	226	194
Joint UK/Australia Weapons Projects	163	163
United States Navy	42	42
Royal Swedish Air Force	10	10
Royal Australian Navy	25	15

Up to 1 January 1974, Jindiviks had flown 2,832 sorties at the RAE, Llanbedr, North Wales and one particular Mk 3A drone had flown 270 sorties at Woomera.

MANUFACTURER:

Department of Supply, Government Aircraft Factories, Pt. Melbourne, Victoria, Australia.

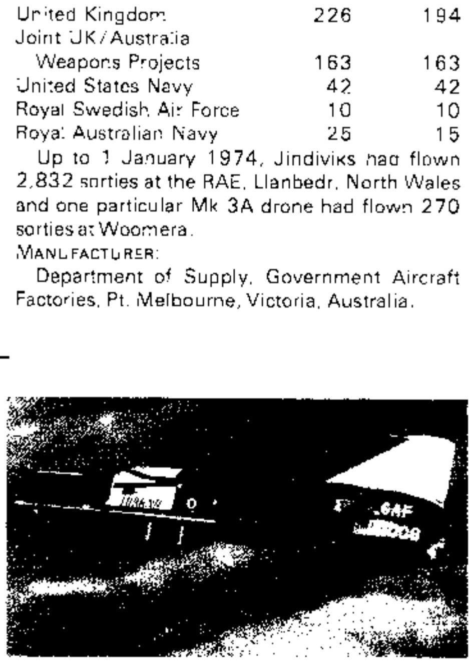
TURANA

DESCRIPTION:

The Turana target drone system was conceived and is designed as an adaption of the Ikara anti-submarine weapon system (**6002.241**) used by the Royal Australian Navy and Royal Navy. Turana is designed for parachute recovery and all elements of equipment are suitable for at least 20 complete missions, including sea water immersion followed by simple refurbishing procedures.

The drone fuselage is a composite metal/glass-fibre structure containing a Microturbo Cougar - 022 engine, fuel tank, control system, power supply, and recovery system. The nose section can be ejected on command by means of a pyrotechnic charge, and it contains a 19 cm diameter Luneberg lens for forward looking passive radar augmentation, and a recovery parachute. A re-



Turana target drone in flight

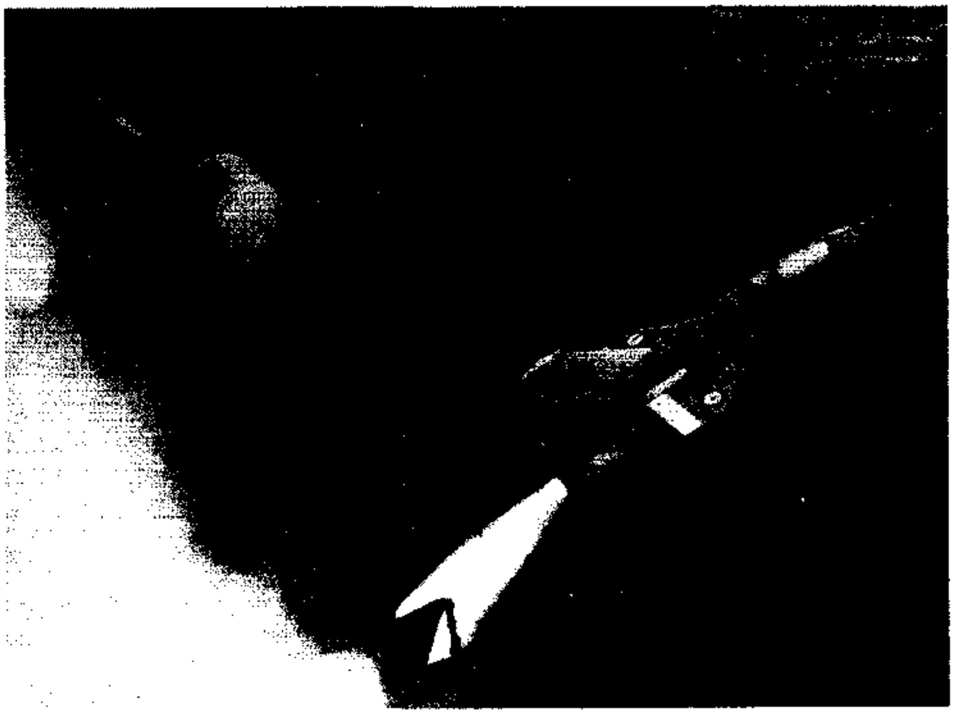
movable bottom fairing, between the nose and the air intake, provides access to a compartment for telemetry or special equipment. The telemetry unit is an Australian developed equipment providing up to 48 channels and operating at 465 MHz. Smoke emission on command is provided for visual augmentation of the target. Flotation is provided by a combination of sealed equipment compartments and integral light foam sections:

Principal dimensions are:

Length	3.37 m
Height	1.01 m
Height (with booster)	1.19 m
Wing span	1.53 m
Weight (less booster)	214.3 kg
Speed at end of boost	177 m/sec
Payload (level flight)	45.5 kg
Operating speeds	150 to 400 knots
Altitudes	15 to 9,144 m

OPERATION:

Turana may be launched from an Ikara ship launcher or from a simple portable unit on board ship or on land. In the former case, the missile handling equipment is used for the insertion of the drone into the launcher. The drone is controlled in flight by means of the target control unit which is connected to either the ship's Ikara Guidance System, or in the case of non-Ikara based operations, directly to a command transmitter. Return data facilities are available, though not essential. If used, flight information is presented to the operator on the target control unit. Navigation is presented by the controller using a plot or a PPI display which is driven by either the Ikara tracking system or any suitable radar. After recovery the target is washed down and given a short engine run. A replacement parachute pack and boost motor are fitted and after checkout the Turana is ready for immediate re-use.



Turana target drone being launched at sea from Ikara ASW missile launcher

DEVELOPMENT:

An Australian Government sponsored programme aimed at meeting a RAN target requirement was approved in mid-1969. Design was undertaken at the Government Aircraft Factories, Melbourne, with assistance from the Weapons Research Establishment, S.A., the Aeronautical Research Laboratories and the Defence Standards Laboratories in Victoria. First flight tests were held at Woomera in March 1971 and were followed by further flights at both Woomera and the RAN Jervis Bay Missile Range (JBMR).

STATUS:

Turana is entering RAN service in 1974 and deliveries against an RAN order have commenced.

MANUFACTURER:

Department of Supply, Government Aircraft Factories, Pt. Melbourne, Victoria, Australia.

BELGIUM

2020.351
EPERVIER

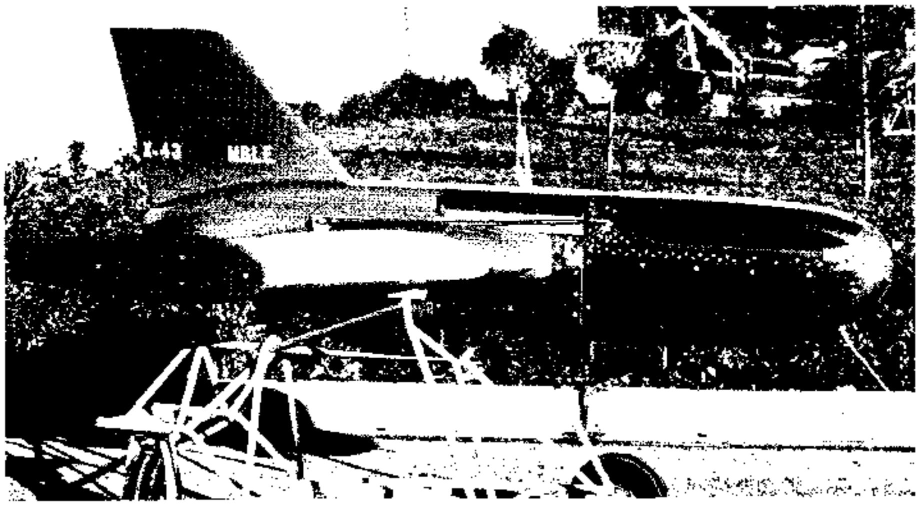
The Epervier is a battlefield surveillance system using a ramp launched remotely-controlled drone.

During a development programme extending over some five years several versions of the system have been created. The latest, the X-5, has a turbojet engine to power the drone, take-off being rocket-assisted, and this gives it a cruising speed which is adequate to satisfy the military requirement.

In designing the system to meet the evident need for positional accuracy in battlefield surveillance, while at the same time keeping its vulnerability to ECM within reasonable limits, the manufacturers have selected a compromise between direct radio control and pre-programmed flight. During the major portion of its airborne mission the drone is controlled either by its autopilot or by an airborne flight programmer; but flight orders or orders to start programmes, start or stop surveillance processes, stop engine and so forth can be given over a command radio link which also interrogates the drone to determine its position.

SPECIFICATION:

Type: Battlefield Surveillance Drone system
Cruising Speed: 500 kmh
Cruising Altitude: 2-3,000 m
Launch Weight: 139 kg
Launch Method: By mobile ramp
Payload: 20 kg
Powerplant: Turbojet, rocket assisted
Length: 2.15 m
Span: 1.70 m
Guidance: Airborne programmer plus digital command link and secondary radar position-finding
Accuracy: Maximum linear error 150 m at 50 km
Recovery: By parachute within radius of 150 m



The X-4 Epervier at Salto di Quirra

The digital command link comprises a ground-based controller and command transmitter and an airborne command receiver and decoder. During flight in a straight line the interval between commands may be very long; the drone meanwhile maintaining its heading and altitude by autopilot control.

The tracking system comprises an airborne transmitter, which responds to interrogations from the command transmitter when instructed to do so by the airborne decoder. The computer transforms the co-ordinates derived from the command/tracking system – which effectively operates as a secondary surveillance radar – into map co-ordinates and operates the pen recorder to plot the drone position. From then until the next interrogation and response it uses the knowledge of the drone's commanded heading, altitude and speed to predict its position, updating that prediction with each successive interrogation.

During programmed flight the drone can execute up to ten orders – such as turns, changes in altitude or starting and stopping cameras – during a flight of up to 80 km. While under programmed control the drone will respond to any order over the command link other than a position interrogation.

These arrangements give the Epervier a good deal of protection against ECM and its small size and relatively high cruising speed makes it a difficult target for anti-aircraft weapons.

STATUS:

The award of a contract for full production of the X-5, as the Belgian Army version will be known, by the Belgian Government was announced in June 1971.

MANUFACTURERS:

MBLE (Manufacture Belge de Lampes et de Matériel Electronique), 80 Rue des Deux-Gares, Brussels 7.

CANADA

2034.351
CANADAIR AN/USD-501 RECONNAISSANCE DRONE

DESCRIPTION:

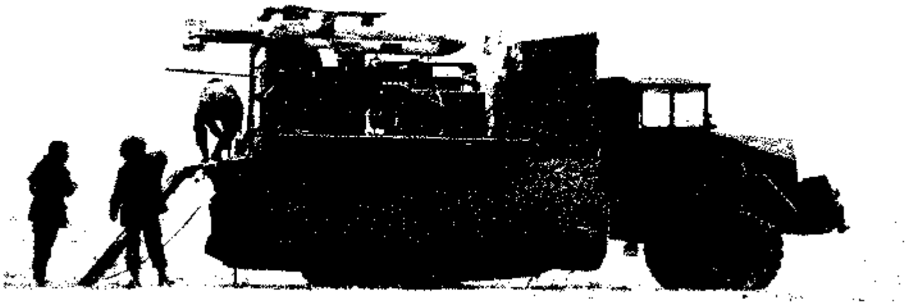
Short-range battlefield reconnaissance drone for day and night surveillance and artillery target acquisition purposes. Configuration of the vehicle is apparent from the illustration and its dimensions are, length 260 cm (plus 113 cm launch booster), diameter 33 cm and wing-span 94 cm. Straight and level speed is 400 knots (740 kph) and range is up to 120 km.

The reconnaissance sensor equipment is carried in a sensor pack located midway between the wings and the forward control fins. The sensor pack is capable of rapid removal and replacement and four versions are available – three photographic and one infra-red linescan. Camera options are KRb 8/24 Carl Zeiss camera, an Itek Corporation twin camera pack, and a Hycon panoramic camera. The IR Linescan is the Hawker Siddeley Dynamics Type 201, which see. The sensors currently in use are the KRb 8/24 and IR linescan.

The AN/USD-501 is powered by a Williams WR2-6 single-stage turbojet which also drives an alternator giving electrical power during flight. Launching from a vehicle-mounted ramp is assisted by a Bristol Aerojet Wagtail booster.

OPERATION:

After launch, the drone's subsequent flight path is pre-programmed and is maintained by DR navigation, aided by a propeller driven air-distance measuring unit, a directional gyro and a vertical gyro. Height is thought to be controlled by reference to a barometric sensor. Operation of the reconnaissance sensor equipment is also pre-programmed, the results are recorded on film for rapid processing after the return of the drone. To the rear of the sensor pack, and on the upper side of the fuselage is a flare pack containing 12 flares which are discharged under the control of a stepper switch. Normal operating height of the AN/USD-501 is between 300 and 1,200 metres.



Preparation for launch of AN-USD-501 drone

Recovery is assisted by an X-band homing receiver working in conjunction with a beacon located at the recovery site. The drone is also equipped with an X-band transponder and this is probably provided to assist radar tracking, both over the target area and during recovery. Shutdown of the motor initiates parachute deployment and the drone is inverted to come to rest on a pair of air-inflated landing bags carried in containers in the upper part of the fuselage.

DEVELOPMENT:

Development was initiated in 1959 by Canadair under the designation CL-89. In 1963 development contracts were awarded by Canada and the UK and the official designation of AN/USD-501 was allocated. In 1965 West Germany joined the programme, costs being shared equally between the three partners. Cost of development reported as £15 million.

An extended fuselage version with the Canadair designation CL-289 has been considered by the West German and other authorities. This would offer increased range/payload advantages.

Future developments which have been considered include a solid-state flight programmer with increased capacity; a real-time data link; alternative sensor system; simulated anti-ship cruise missile systems; and automation of mission planning and programming, and maintenance.

STATUS:

Production was started in 1967 and over 110 test flights were made in the course of evaluation trials. 90 of these took place at Yuma Proving Grounds, in Arizona, a US Army facility, and a further 20 flights were carried out by a three-nation proving team at Camp Shilo, Manitoba. These are reported to have been extremely successful. A total of nearly 300 drones had been ordered at June 1970 at a cost of approximately £28 million. Additional quantities have since been ordered by Britain and Germany, bringing total production to early 1973 to more than 400. Deliveries have been made to the armies of all three participating countries and in June 1971 it was evaluated by the Italian Ministry of Defence, and a production agreement was concluded between Canadair and Meteor SpA. The system is in service with the armies of Britain and Germany.

MANUFACTURER:

Canadair Ltd, Cartierville Airport, Montreal, Canada.

FRANCE

2123.351
NORD 510 FLYING PLATFORM

DESCRIPTION:

The Nord 510 Flying Platform has been designed by their Shrouded Propeller Vehicle Department as the modern all-weather counterpart of a captive observation balloon. It is the vehicle part of Project Orphée (Observation Radar Par Hélicoptère) which is described as having a potential surveillance range of several dozens of kilometres.

The captive platform can rise to a height of 300 metres above the lorry which carries it and the control gear. It is powered by a Turbomeca Astazou II turboprop engine driving a horizontal, shrouded four-blade propeller of diameter 1.8 metres. This produces an excess of lift over platform weight of some 500 kg but this is reduced by the cable weight.

STATUS:

At the 1974 Hanover Air Show the Dornier company revealed the information that a French Orphée radar was being considered as a payload option for the Kiebitz tethered reconnaissance platform (Entry **2183.351**), which suggests that SNIAS and the German concern may now have combined their respective efforts in this area into a single project.

MANUFACTURER:

Société Nationale Industrialle Aérospatiale, Division Engins Tactiques, 2 rue Béranger, 92320-Chatillon, France.

2127.351
NORD R 20

DESCRIPTION:

R 20 is a battlefield reconnaissance drone developed from the Nord-Aviation CT 20 target drone. Like the CT 20 it is ramp-launched with the aid of two solid-propellant booster rockets, after which it is powered by a Marboré II turbojet.

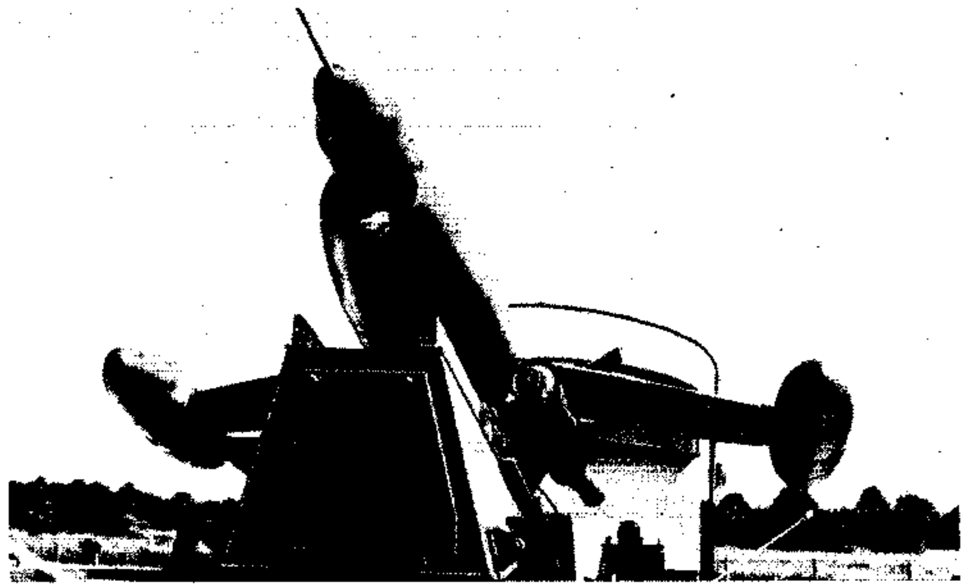
Standard NATO cameras and other surveillance equipment are carried by the drone, which can photograph more than 200 square kilometres of territory in a single sortie. Radio-controlled when near the launch vehicle, the drone is autopilot guided over the major part of its flight; and an over-target accuracy of 300 metres at 100 km range is claimed. An electronic programme is carried and this enables the R 20 to follow a reasonably complicated flight plan.

Operating speed is Mach 0.65 and operating radius at low altitude is 160 km.

In 1974 it was revealed that an improved version, designated R 21, was under study.

MANUFACTURER:

Société Nationale Industrielle Aérospatiale, Division Engins Tactiques, 2 rue Béranger, 92320-Chatillon, France.



R20 battlefield reconnaissance drone

2125.391
AEROSPATIALE CT 20

DESCRIPTION:

The CT 20 is a turbojet-powered radio-controlled target of medium performance, which can also be used as a tug for a towed target. It is standard equipment for training military units in the use of air-to-air and surface-to-air missiles – notably the Hawk; and over 1,200 have been sold to French, Italian, Swedish and other armed forces.

LEADING PARTICULARS:

Power Plant: One Turbomeca Marboré II, IV or VI turbojet engine

Remote Control: From ground or airborne station. Automatic descent in case of radio control failure

Take-off: From launching carriage powered by powder rockets on 10 metre ramp. 7.5 g acceleration

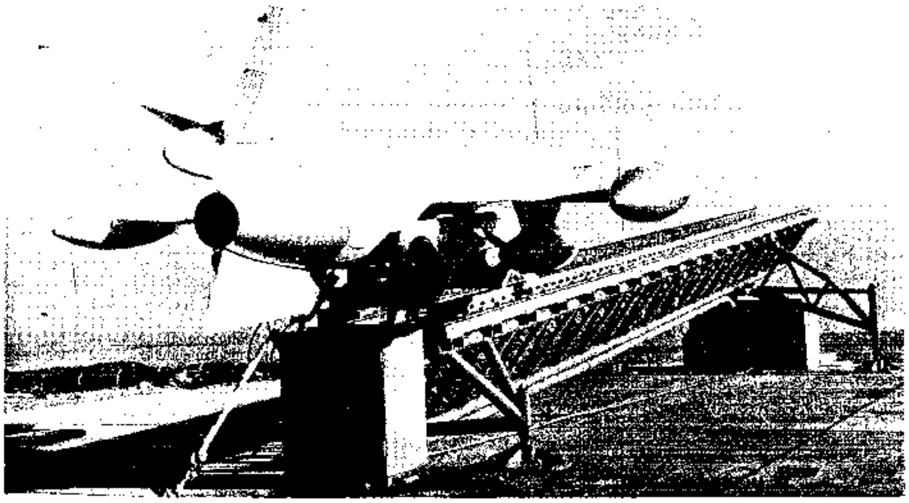
Max Speed: at 10,000 m 900 kmh with Marboré II or 950 kmh with Marboré VI

Rate of climb: Time to 10,000 metres, 6 min

Service Ceiling: 12,000 m or 15,000 m with Marboré II or VI

Endurance: Mean 60 min

Special Features: Low altitude flight can be programmed down to about 100 metres. A very low altitude version, the CT-20/TBA has been developed with height control by a TRT AVH-6 radio altimeter. This permits operating heights down to 30 m. This model also incorporates different control and telemetry sub-systems.



Nord CT20 drone on launcher. A Dornier System SK3L towed target is carried under the starboard wing

Drone can be used to tow an SK3L Dornier target with no more than 15% loss of performance.

The last-mentioned feature is important because of the difficulty of using piloted aircraft to tow targets for some modern weapons. It is the result of a joint development by Nord-Aviation and Dornier System GmbH.

MANUFACTURER:

Société Nationale Industrielle Aérospatiale, Division Engins Tactiques, 2 rue Béranger, 92320-Chatillon, France.

1808.391
HALBRAN TARGET-MISSILE

DESCRIPTION:

Low cost, ballistic trajectory target-missile intended for the training of military units using either small calibre ordnance, or short range surface-to-air missiles.

The Halbran target missile is available in two versions: (I) for light gun firing, 5 km range, (II) for surface-to-air missile firing, 13 km range.

The target-missile comprises

- the propulsion system, consisting of a solid propellant rocket motor and graphite nozzle, a tail unit, smoke generators, and the igniter, fastened on a diaphragm that seals off the motor;
- the target body, consisting of a laminated plastics cylinder, non-reflective to electromagnetic waves, and a nose cone.

Simple missile assembly can be performed directly on the launch pad. Launching is achieved from a readily operated launch ramp, adjustable in elevation and azimuth angle. The rocket motor delivers a single thrust level in version I, and two thrust levels in version II. The tail unit includes off-set fins which cause spinning of the target, for stabilisation.

MAIN CHARACTERISTICS:

	HALBRAN I	HALBRAN II
Range:	5 km	13 km
Maximum altitude:	1,200 m	3,500 m
Speed:	310 m/s	370 m/s
Radar reflecting surface	1 m^2 in bands L, S, X	
Length:	2.586 m	2.994 m
Diameter:	0.227 m	
Mass:	58 kg	80 kg
Lateral deviation:	15% of the range at three standard deviations	

Optional on board equipment:

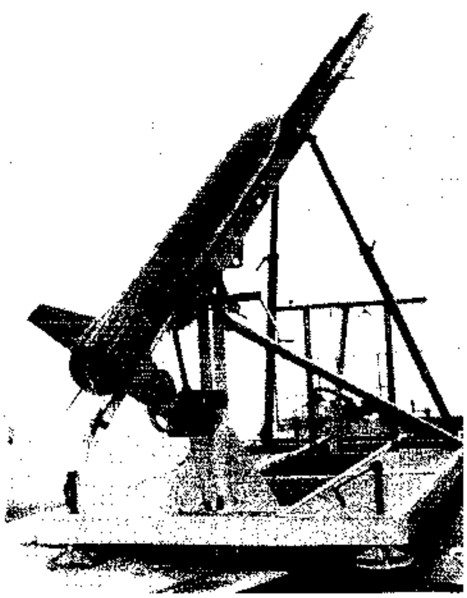
Smoke composition tracers

Radar reflectors: luneberg lens or "candle like" reflector

Acoustic scorer capable of generating a high intensity flash of light on passing of a supersonic projectile close to the target, or of being fitted with a transmitter enabling ground scoring of "direct hits".

DEVELOPMENT:

Halbran target-missile has been developed by Société Européenne de Propulsion under DRME contract (Direction des Recherches et Moyens d'Essais, Service des Equipements des Champs de Tir).



Halbran target-missile ready for launch

MANUFACTURER:

Société Européenne de Propulsion, 3 Avenue du Général de Gaulle, 92-Puteaux, France.

GERMANY (FEDERAL REPUBLIC)

2183.351
DORNIER EXPERIMENTAL KIEBITZ (PEEWIT) DO 32 K

The aircraft/helicopter division of Dornier GmbH has developed a mobile drone system, designated Do 34 Kiebitz, based on the Do 32 K experimental Kiebitz.

The experimental Kiebitz was developed, under contract from the Federal Ministry of Defence, to evaluate the feasibility of an automatically stabilised tethered rotor platform, capable of utilising sensors for reconnaissance, communications and ECM purposes at an altitude which considerably increases their effectiveness.

The rotor and transmission system, comprising a two-blade "cold jet" rotor, driven by compressed air from a KHD T 212 turbine and turbo compressor, were taken from the Do 32 single-seat helicopter, and the flight control system and the servo motors for rotor blade pitch control from the Do 32 drone helicopter. The complete system consists of a tethered rotating-wing platform (first demonstrated in flight in late 1970) and a mobile ground station such as a truck or tracked vehicle. Fuel for the turbine is fed through the tether by means of a pump installed in the ground station, making possible long periods of operation. The rotor turns at 340 rpm.

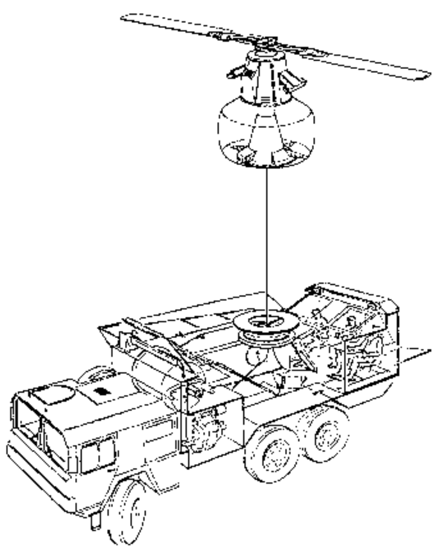
The platform contains a three-axis autostabiliser which works through the cyclic pitch control system and compressor exhaust control system. The ground vehicle serves as transporter, take off and landing ramp, and power supply station. An easy to operate winch permits the drone to be reeled in and out at a rate of 590 ft (180 m)/min. De icing and a high degree of weather resistance make operations almost independent of weather conditions.

The Kiebitz is intended for use as an emergency transmitter aerial in the long, medium and short wavebands; as a relay and directional station for TV, VHF and radio communications; for measurement of field strength for localising optimum transmitter positions, photographic survey and reconnaissance, meteorological measurements or radar reconnaissance to detect low-flying objects; and as a directional receiver. Power supply on board the vehicle is 200 W 28 V DC.

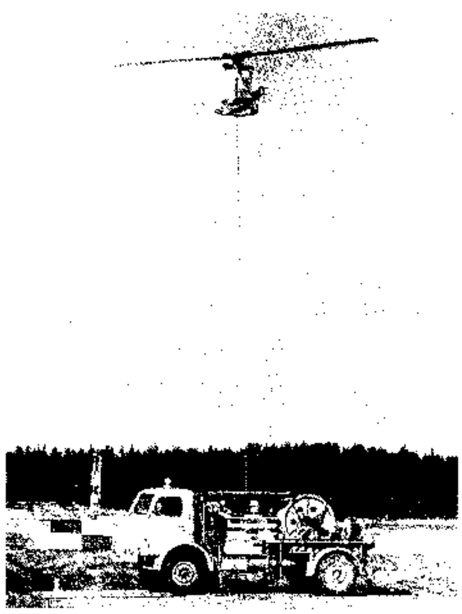
Five experimental rotating-wing vehicles were built, and these completed approximately 100 hours of successful test flying, including take offs and landings using a very short tethering cable and tethered flights to an altitude of 200 m. Following successful completion of the tests designed to perfect the flight control system, calculations were made to evaluate the detectability of the Kiebitz. In addition to measurement of the vehicle's infra-red radiation and radar profile, details were also obtained of the distances at which the rotor platform is discernible acoustically and optically. Also, so far as possible with the experimental vehicle's payload capacity, tests were performed with applications sensors. These included an RDF system, developed by Dornier, which used the Kiebitz rotor as an integral part of the D/F system by means of a blade-tip antenna; and a Grundig television camera, with oscillation-damping suspension and Dynalens lens-stabilisation, to determine the feasibility of such an installation for reconnaissance and surveillance purposes.

Dimensions, external:
Diameter of rotor: 7.50 m
Height overall: 1.60 m
Body diameter at bottom edge: 0.75 m
Weights:
Weight without tether and without payload: 200 kg
Max payload to 200 m, ISA: 50 kg
Performance:
Reel-in / Reel-out speed: 1.5 m/sec
Operational ceiling: 200 m

The experimental programme is still active, especially for payload and sensor investigations.



Arrangement of Do 34 Kiebitz



Do 32 Experimental Kiebitz

DORNIER DO 34 KIEBITZ

PLATFORM:

The rotor's twin blades are suspended on straps and driven by cold air expanded through the blade-tip nozzles. No torque which could act on the platform is produced with this drive principle.

The Kiebitz has undergone a further engine change, and air for the rotor blades is supplied by a radial compressor and an Allison 250-C20 shaft turbine. The turbine is installed on the slant, which makes for good positioning of the intake. The payload compartment is located on the underside of the airframe, this arrangement enabling sensors to be changed quickly and space for a large volume radome. A cone-shaped airframe has been selected to reduce radar reflection.

The complete system is vehicle housed, and consists of a landing platform, winch system, guidance and control post, flight vehicle and sensor, check-out system, fuel tank for 12 hours operation, and auxiliary equipment. After arrival on site, the drone can be in position at an operational height of 300 metres in eight minutes.

In the guidance and control system the determining factors here are the required wind speed of 14 m/s + 8 m/s, the available thrust reserves, and the requirements of the various sensors. These different factors led to a control system which aligns the Kitbitz according to airframe attitude and position in relation to the ground – a drift control system with the drift from the desired position being measured by an electromagnetic sensor. The flight vehicle's control and guidance system and the display and operating equipment in the ground station enable the Kiebitz to meet a wide variety of requirements as a sensor carrier.

SENSORS:

A tethered rotor platform is basically suited for the following land and sea missions:

(1) reconnaissance and surveillance
(2) electronic countermeasures
(3) fire control
(4) telecommunications and data-transmission

Within this wide spectrum of applications a number of specific sensors are under consideration and are being examined:

Battlefield Reconnaissance Radar: A bilateral agreement between Germany and France has been signed to define, integrate and test the battlefield reconnaissance system Argus (Entry **1809.351**) which consists of the Kiebitz rotor-platform and an advanced version of the LCT Orphée Radar.

Passive Electronic Warfare Equipment: Operational trials will be carried out with the Dornier experimental Kiebitz and the Decca RDL-2. The Decca RDL-2 consists of a high probability of interception display, automatic and visual pulse analysis, band and frequency measurement. Discussions are in hand with several armed services on the possible merits of this (passive) and active ECM equipment aboard the Kiebitz.

Naval Strike and Surveillance System – Sea-Kiebitz: The performance of current on board missile guidance or target detection equipment on ships is severely limited by the height of masthead aerials. The strike range of medium range missile systems is therefore limited. This can be avoided by the use of Sea-Kiebitz, a combination of the Kiebitz rotor platform and the Ferranti Sea Spray Radar (**1342.353**), as a missile guidance and surveillance aid for FPB's and ships. Experimental trials are being discussed at this time.

Low Flying Aircraft Detection Radar: Aircraft flying in the shadow of hills are detected too late by ground based low flying aircraft detection radars. The reaction time is too short to guarantee an effective defense. Due to its mission height of 300 m the Kiebitz equipped with a suitable radar extends the range considerably.

Data (Do 34):
Dimensions, external:
Diameter of rotor: 8.00 m
Height overall: 1.45 m
Body diameter of bottom edge: 1.05 m
Weights:
Weight without tether and without payload: 285 kg
Max. payload to 300 m, ISA: 140 kg
Performance:
Reel-in / Reel-out speed: 3 m/sec
Operational ceiling: 300 m

STATUS:

The definition phase was completed in October 1971 after which the design phase was commenced. Dornier has stated that a system will be available by 1975. The first flight will take place in autumn 1974.

MANUFACTURER:

Dornier GmbH, 799 Friedrichshafen, Bodensee, West Germany

1537.351
DORNIER AERODYNE E1

DESCRIPTION:

Development of the Aerodyne wingless high-speed VTOL drone was begun by Dr. A. Lippisch in the USA and is being continued by Dornier GmbH. The general appearance of the Aerodyne is shown in the accompanying photograph. The experimental Aerodyne E1, which was developed from 1968 to 1971 and successfully flight-tested in 1972, is about 18 ft 0 in (5.5 m) long and weighs approx 959 lb (435 kg). It is powered by a 370 shp MTU 6022 A3 turboshaft engine. Lift and propulsion are generated by a shrouded propeller, the slipstream from which is deflected downward by vanes for vertical take-off and landing. Control is by deflection of the turboshaft exhaust, which emerges at the end of the tailboom, and by a flap in the propeller slipstream.

Hydraulic actuators are used for the controls and are governed by the on board attitude control system. The Aerodyne is flown by a ground pilot via a radio link. It is equipped with a 58 channel telemetry system. Hovering flight tests have shown extremely smooth attitude stabilisation and very low ground-effect.

Features of the Aerodyne are simplicity, VTOL capability with low fuel consumption, high speed capability and easy handling. These features give exceptional usefulness for a broad variety of landbased and ship borne RPV-missions. Special interest exists for reconnaissance and fire control.

STATUS:

In parallel with the continuing experimental programme with the Aerodyne E1, mission analysis and parametric studies are being carried out

Dornier Aerodyne wingless high-speed VTOL drone to define operational Aerodyne versions for a variety of operational tasks. Dornier GmbH and Hawker Siddeley Dynamics have established co-operative arrangements in the field of Aerodyne systems.

MANUFACTURER:
Dornier GmbH, 799 Friedrichshafen, Bodensee, West Germany.

1810.391
DORNIER AERIAL TARGET SYSTEM (DATS)

DESCRIPTION:
The Dornier aerial target system DATS can be adapted to a wide variety of aircraft and target drones. It consists of the airborne and the ground system. The airborne system incorporates an automatic tow reel with cable cutter, a launcher to carry the tow target during the towing vehicle's take off and the tow target. The tow target is a streamlined body with cruciform stabilising fins made of glass fibre reinforced plastic. For optical, radar and/or infra-red augmentation it will be equipped to meet specific requirements with twelve remote ignitable smoke cartridges, a radar reflector, and instead of the smoke cartridges, with four IR-flares. Mixed operation with six smoke cartridges and two IR-flares is also possible. Further an acoustic or electromagnetic miss distance indicator can be installed. After completion of a mission the tow target is recovered by parachute.

Using an aircraft as towing vehicle, tow reel, launcher and control sensors will be installed into a special pylon (target launch unit) which is mounted either directly to the aircraft's wing or locked to the standard armament pylon of the aircraft. The aircraft will be fitted out with two target launch units, one each under the left and right wing. Controlling of the two launch units is performed by one target control unit from the cockpit.

With a target drone as towing vehicle, the tow reel is mounted into the fuselage of the drone and the launcher under its wing. Target release is remotely controlled. The ground system incorporates a command unit for remote ignition of pyrotechnic augmentation aids in the tow target, the MDI ground station for monitoring and recording of the hit result, as well as several tests sets and tools. Two basic types of two targets equipped due to specific requirements are available: (1) the smaller DS-SK 4, mainly used with target drones, and (2) the larger DS-SK 5, used with manned aircraft. Main components of the two types are interchangeable. The ground system is for both types almost the same.

INTERNATIONAL

1809.351
ARGUS SURVEILLANCE SYSTEM

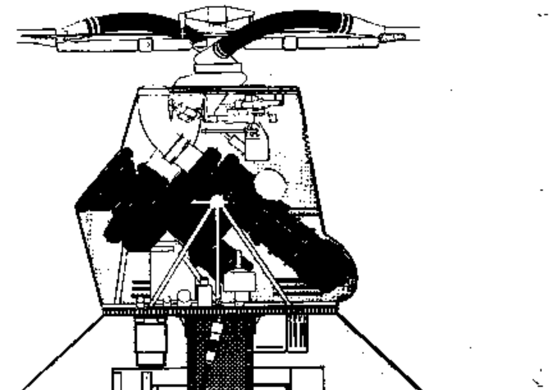
DESCRIPTION:
On March 6, 1974 the governments of the Federal Republic of Germany and the French Republic signed an agreement covering the joint production of a prototype of the Argus battlefield surveillance system. This system consists of a Kiebitz (Entry No. **2183.351**) tethered rotor platform from Dornier GmbH, of Friedrichshafen, and the Orphée radar sensor from LCT (Laboratoire Central de Télécommunications), of Vélizy-Villacoublay.

The prime contract for coordinating the integration of this system and its testing was awarded to Dornier. Cooperation between the authorities and industry is controlled by an Argus Steering Committee representing the German and French governments.

Kiebitz experimental units have so far flown more than 100 hours on 900 flights at altitudes up to 200 m. The continued development of the Kiebitz initiated by Dornier in August 1972 under a preliminary contract from the Federal Ministry of Defence forms the basis for the German share in the Argus system. The radar sensor installed on the Kiebitz rotor platform will be an advanced version of the Orphée radar developed and successfully tested by LCT in France over the past years under contract to the Délégation Ministérielle à l'Armement (Section d'Études et Fabrications des Télécommunications). A modernised version of Orphée (Observatoire Radar Porté par Hélicoptère) will be used. The original model was for installation in a Nord 510 helicopter but the project was allowed to lapse.

Apart from the tethered and remote-controlled Kiebitz rotor platform and the Orphée radar system, the complete Argus system consists of a mobile ground station and a tethering cable.

The ground station is housed in a container mounted on a 7-ton cross-country truck. The container is furnished with all the equipment required for transport purposes and for a twelve-hour operation of the system (e.g. a measuring system for exact determination of the Kiebitz position and instruments for the transmission and evaluation of the data supplied by the radar).



Argus system drone layout

If the radar sensor is raised to an altitude of at least 300 m above ground, the Argus system can be used to detect, identify and track vehicles over great distances. The Argus system thus makes a substantial contribution to surveillance of the battlefield in depth.

It is likely that the Decca Radar RDL-2 series of passive electronic warfare equipment, which was the subject of earlier collaboration between Dornier and Decca, could be one of a variety of payloads that could be lifted by Kiebitz for differing battlefield surveillance and reconnaissance roles.

MANUFACTURERS:

Dornier GmbH, Friedrichshafen, West Germany.

LCT – Laboratoire Central de Télécommunications, Velizy-Villacoublay, France.

ITALY

2236.391
METEOR DRONES

Meteor SpA has developed and produces for the Italian and foreign armed forces a range of propellor-driven and turbojet powered radio controlled drones covering a speed range between 600 km/h and Mach 2.8 at altitudes ranging from sea level to 25,000 m. The company also produces under licence the Northrop NVM-1, NVM-2, and USD-1 drones, and co-produces with Aérospatiale the CT-20 target drone, with Canadair the AN/USD-501 surveillance drone, and with Beech Aircraft Corporation, the BM-1 target missile system. The characteristics of some drones developed and produced entirely by Meteor are briefly noted below.

The Meteor P1 is a sub-sonic target drone used for training with directed anti-aircraft batteries of both medium and large calibre, and ground-to-air missiles. Speeds up to 500 kph are possible and the minimum radius of turn is 750 metres. Operating altitudes range from 500 to 9,000 m. Radar target augmentation can be provided by either passive (Luneberg lens) or active (transponder) means. MDI and flight data can be telemetered to a ground station.

The drone is powered by a 100 hp Meteor Alfa 1 four-cylinder, X-type two-stroke air cooled engine with compressor, driving a variable pitch propeller. Launching can be effected from ground or ship by means of a ramp and a re-usable Meteor 8785/LNZ solid-propellant booster providing a thrust of 2,300 kg.

Control is by radio command link, providing proportional commands in altitude and steering, and on-off commands for automatic altitude hold, wing controls, flares, automatic recovery, etc.

This version is in use by the Italian and South African Forces.

The Meteor P1/R is a reconnaissance version of the P1, with appropriate modification for this role. These include a zero-length ramp and the addition of a programmed guidance system. This system is used for part of a mission, normal radio command link being used for the despatch and recovery phases, the latter being by parachute. Tracking is by means of radar and a transponder carried by the drone.

Reconnaissance sensors include cameras and TV equipment. Sensors are carried in a pod which may be recovered separately.

The PX drone is available with either of two alternative power units, McCulloch 0.100.1 (70 hp) or 0.100.3 (90 hp). These two versions complement the Meteor P1, and having lower maximum speeds, corresponding to the lower power of their engines, and are appropriate to the use of lower performance guns and missiles than those for which the P1 was designed.

MANUFACTURER:

Meteor SpA, Costruzioni Aeronautiche ed Elettroniche, 146 Via Nomentana, 00162-Rome, Italy.

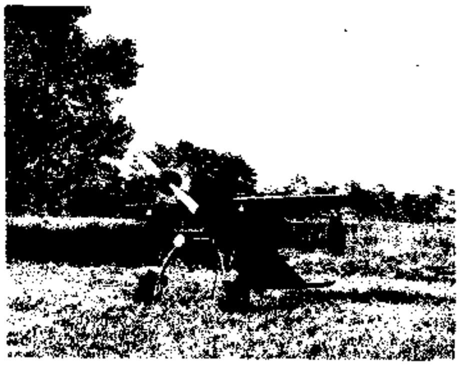
Launch of Meteor PX target at sea

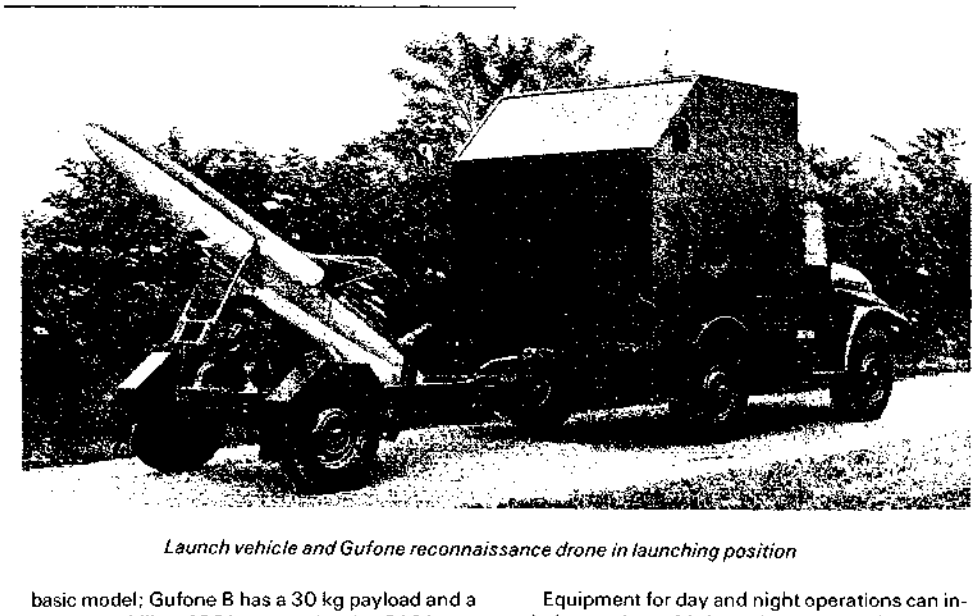


Meteor PI/R reconnaissance drone on mobile zero-length launcher

1345.391
GUFO TACTICAL RECONNAISSANCE SYSTEM

DESCRIPTION:

This system comprises the ground equipment and drones required for tactical reconnaissance by normal optical cameras or infra-red techniques over enemy territory. Based on considerable experience in drone and RPV development, Meteor has evolved the Gufo tactical reconnaissance system to meet anticipated requirements in the 1975-1985 period. The system is claimed to be particularly suitable for use in mountainous country. Payloads up to 30 kg can be carried at speeds of up to 740 km/h to target areas within a range of 200 km from the launch site. Recovery to within a radius of 100 m can be achieved. The Gufo system utilises the Gufone (Owl) drone, which is a modified Northrop Chukar (MQM-74A) target drone. Modified by Meteor to carry new guidance equipment and sensors, and equipped with inflatable bags to absorb landing shocks, the Gufone is employed in three versions. The standard Gufone has a payload capacity of 30 kg and a penetration capability of 55 km at sea level to 135 km at 10,000 m; Gufone A has double the payload capacity but otherwise is similar to the basic model; Gufone B has a 30 kg payload and a range capability of 90 km at sea level to 210 km at 10,000 m.



Launch vehicle and Gufone reconnaissance drone in launching position

Equipment for day and night operations can include a variety of infra-red sensors and cameras using 50, 70, or 75 mm film to photograph a strip of terrain more than 102 km long and, respectively, 1000 m, 2000 m, or 3000 m wide, from heights of 305 m, 610 m or 915 m.

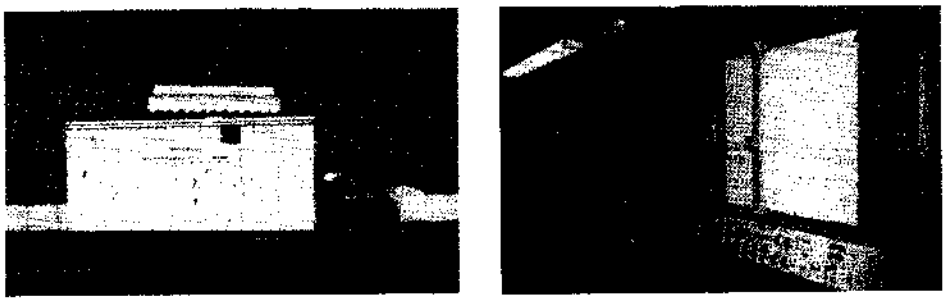
For night operations, the Gufone can carry 14 wingtip flares which are released at predetermined intervals. At take-off, the 55 kg st turbojet engine is supplemented by two Meteor 8785/CNS solid-propellant jettisonable boosters, providing a total thrust of 2,600 kg for 0.7 second.

A military unit deploying the Gufo system is comprised of four sections:

(1) Launch
(2) Guidance and Control
(3) Sensor Recovery, Interpretation and HQ
(4) Vehicle Recovery and Preparation

The launch section is equipped primarily with two launch trucks, each towing a launch trailer carrying one Gufone drone ready for flight, with each launcher supported by a Land Rover which is used to ferry empty launch trailers to the vehicle recovery and preparation area, returning with another flight-ready drone. The maximum launch rate from each launch truck is one drone per 10 minutes.

The guidance and control section is equipped with a medium-size truck on which is the Drone Control Centre. This contains a guidance station, tracking and plotting system, and computer. Since it can control only one drone at a time and the Gufone has an endurance of about one hour, the first-line equipment needed for continuous 24-hour surveillance comprises one DCC, two launch trucks, two launch trailers, and 24 drones. In addition, the sensor recovery, interpretation and HQ section normally will use a film processing and interpretation truck, one or more HQ vehicles, and if required, a 'receiver' truck for telemetered data, plus the necessary transport arrangements for sensors between recovery areas and processing vehicles.



External and internal views of Gufo system control vehicle.

DEVELOPMENT:

Design studies were commenced by Meteor SpA in 1969.

STATUS:

Flight trials have been carried out but no details of production contracts have yet been released.

MANUFACTURERS:

Meteor SpA, Via Nomentana 146, Roma, Italy.

Northrop Corporation, Ventura Division, Newbury Park, California, USA.

CONDOR AND SUPER-CONDOR TARGET DRONES

DESCRIPTION:

The Condor and Super-Condor are inexpensive target vehicles based on the self-pressurised, prepackaged liquid propulsion rocket technique developed by SAI-Ambrosini. In this case, a two-stage rocket configuration is employed, the rocket only becoming live at launch, resulting in complete safety in transport, storage and handling. Condor is designed to have a shallow trajectory, and is able therefore to simulate the following: in the initial part of its trajectory, the aircraft pull-out after an attack; in the central part of trajectory, which is essentially level, a napalm delivery; and in the last part of flight, a rocket or cannon attack. Visibility of the rocket in the low-level simulation is good, but this is augmented by the steam trail of the sustainer. Launch is effected from a simple, light-weight ramp. Super-Condor is similar in most respects except for dimensions and higher performance, and is intended for the same type of training missions as Condor.

CHARACTERISTICS:

Body diameter: 108 mm
Overall length: 2,640 mm
Fin span: 442 mm
Take-off weight: 41 kg

	Condor I	**Condor IV**
Max range:	2,700 m	8,500 m
Max altitude:	490 m	2,200 m
Max flight time:	21.2 sec	45 sec
Average flight speed:	120m/sec	190m/sec
Take-off acceleration:	120m/sec^2	224m/sec^2

Super Condor

Body diameter: 280 mm
Overall length: 5,360 mm
Fin span: 780 mm
Take-off weight: 296 kg
Max range: 8,500 m
Max altitude: 1,800 m
Max flight time: 44 sec
Average flight speed: 186 m/sec
Take-off acceleration: 195 m/sec^2

SHORTS SKYSPY SURVEILLANCE DRONE

DESCRIPTION:

In concept Skyspy represents a new type of aerial vehicle designed from the outset as a drone, free from the restraints of manned flight. It derives its lift and propulsion forces by vectoring the gross thrust output of a low-pressure ducted fan, augmented by aerodynamic force components generated on the duct surfaces and intake lip. Skyspy is remotely controlled, is powered by an efficient piston engine, with a low IR signature, and has a small radar echoing area. It provides a stable platform for its airborne sensors and systems at all airspeeds from hover through to maximum speed in the conventional forward flight mode. When fitted with its payload of sensors the vehicle is intended to detect, position or track targets in real time and relay this information, using secure data links, to a ground or ship-based controller. Many other applications are envisaged for Skyspy including the capability of providing a command link for over-the-horizon weapon control systems.

Whilst being of simple, compact design the following features are inherent in Skyspy:

Stabilised aerial platform
Quiet noise levels
Very small visual silhouette
Faint radar echo
Vectored ducted-fan thrust
VTOL and hover performance
Conventional forward flight
Low susceptibility to gusts
Weak IR signature
Modular construction
Low damage risk
Transportable by land, sea or air
Low cost power unit

The vehicle consists primarily of a centrebody carrying the engine, fuel, control and stabilisation actuators, low-pressure fan, and an axi-symmetric duct connected to the centrebody by an engine mounting spider and by stators. Aerofoil surfaces for pitch, roll/yaw and rotational stabilisation and control are set across the duct exit and integrate, in part, with low aspect ratio wings located on the exterior of the duct. The centrebody comprises the major part of the vehicle weight; the duct being a simple, light but rigid structure. An equipment (payload) pod is located on the forward duct support structure and the autopilot and power supply equipment are at the rear, in the wall of the duct. The resulting vehicle is structurally and mechanically simple and relatively inexpensive.

A very wide variety of applications for Skyspy are envisaged as indicated below. The all-up weight, payload, equipment standard and ground facilities provided are directly related to the operational role requirements.

Model of Short's Skyspy ducted fan surveillance drone

Army reconnaissance
Naval over-the-horizon viewing
Weapon control and delivery
Target spotting
Coastguard surveillance
Border patrol and police duties
Fishery protection
Search and rescue operations
Forest fire spotting

Emergency relief and medical support service

Skyspy can be engineered in a variety of sizes with little extra development required, and using suitable available power plants. Typical characteristics quoted are a payload of 30 kg carried by a 1.2 metre diameter vehicle, powered by an 80 hp engine, and a mission duration of up to two hours. Studies are in progress for the use of turbine engines in Skyspy vehicles for roles which demand larger and more sophisticated payloads and improved performance.

MANUFACTURER:
Short Brothers & Harland Ltd, PO Box 241, Airport Road, Belfast BT3 9DZ, Northern Ireland.

1811.391
AEL FALCON DRONE

DESCRIPTION:

The Falcon low-cost, reusable short-range aerial reconnaissance system based on the Falcon unmanned miniature aircraft is the product of three years of continuous development based on an original idea from the Royal Military College of Science, which recognised the merit of a versatile, simple, rugged and very low-cost miniature aircraft.

Falcon forms the nucleus of a range of training and operational systems and is itself one of a series of similar aircraft, each having characteristics that match particular applications.

The Falcon reconnaissance system (FRS) uses a radio-triggered automatic 35 mm camera, which provides up to 20 high-definition photographs from altitudes up to 900 m and operating at ranges out to 3 km from the controller. Target location is achieved by photo/map comparison and Falcon can be positioned for photography at maximum range in as little as 4 minutes from the decision being taken.

At regimental level, FRS is used to check camouflage effectiveness and to reconnoitre deployment areas.

Due to Falcon's small size, high speed and inherent structural ruggedness, it is not vulnerable to small arms fire and its very low radar and infrared signatures prevent detection by more sophisticated systems.

The effectiveness of low-level air defence systems such as Rapier, Blowpipe and light anti-aircraft guns, is critically dependent on the operator's skill, both in acquiring and in tracking the target aircraft. Realistic training is essential, ideally with high-speed aircraft practising ground attack runs. Falcon approaches this ideal since it accurately simulates such aircraft in appearance and crossing rates, yet at negligible operating cost. It can be operated from within a unit's area with a mission response time of under 4 minutes, thus giving regiments their own 'air support'. Falcon is equipped with X and S band radar enhancement devices and can thus alarm related surveillance radars enabling the complete engagement sequence to be practised.

Falcon can tow a 3 m drogue target (a standard accessory) on a 150 m line for live firing practice.

The standard FRS kit allows the Falcon to be used for offensive action. Up to six 1 kg napalm or anti-personnel bomblets can be carried and can be released individually or simultaneously by radio command.

Launching and retrieval can be made as with an orthodox aircraft from flat ground, or where this is not possible, a catapult launcher and catching net are available as standard accessories. The Falcon has a measure of auto stabilisation; the required flying skills can be gained by a trainee with average aptitude in a five-day course of instruction.

CHARACTERISTICS:
Configuration: Delta
Span: 2.55 m
Length: 0.65 m
Weight: 9.1 kg
Engine: 4 bhp, 45 cc
Fuel capacity: 80 cc
Flight duration: 16 minutes
Radio guidance system: Hand-held 3 W transmitter with output fed into a quarter-wave horizontal dipole on a 3 m alloy mast of 25 mm diameter
Operating range (with optical system): 3 km
Speed: 224 km/h (120 knots)
Landing speed: 37 km/h (20 knots)
Payload: 5.4 kg
Maximum controlled altitude: 915 m at 3½ km

STATUS:
The Falcon system has been supplied to the Libyan Armed Forces.

MANUFACTURER:
Aero Electronics (AEL) Ltd, Gatwick House, Horley, Surrey, RH6 9SU, England.

1885.391
PETREL TARGET

DESCRIPTION:

The Petrel is a non-recoverable supersonic ballistic target developed from the well-known and extensively used Petrel research rocket. It is designed to simulate a missile threat and is used for defence weapon system development and evaluation, and for crew training. A variety of passive radar augmentation systems are provided, depending upon the nature of the trials being carried out. A benefit arising from the development of this target from a research rocket is that the low dispersion which was demanded of the research Petrel means that, although unguided, Petrel may be used for target applications where the permissible range areas are restricted.

CHARACTERISTICS:
Length: 3.35 m
Diameter: 19 cm
Main Motor: Lapwing
Boost Motor: 3 × Chicks
Range: Variable with launch angle – 22,500 m at 30° app
Altitude: Variable with launch angle – 1,200 m at 30° app. 160 km at 86° app
Speed: Variable with launch angle – near Mach 3 at low angles, can be reduced with drag devices
Time of flight: Approx 30 seconds at low launch angles

DEVELOPMENT:
Developed as a research rocket, but now additionally used for target applications. The Bristol Aerojet Skua research rocket also is available for use as a supersonic ballistic target.

MANUFACTURER:
Bristol Aerojet Limited, Banwell, Weston-Super-Mare, Somerset, England BS24 8PD.

THE UNITED STATES OF AMERICA

1812.391
LAST – LOW-ALTITUDE SUPERSONIC TARGET (XBQM-8)

DESCRIPTION:

LAST (Low-Altitude Supersonic Target) is a conversion of the RIM-8D and RIM-8F Talos naval missile (**1030.231**) designed to act as a low cost target to provide threat simulations against the US Army SAM-D (**2800.131**) and US Navy Aegis (**2507.231**) air defence weapon systems. Modifications to the normal Talos round include the provision of a new tracking beacon, a radar altimeter and an on-board command receiver. There is additional payload capacity for such options as miss-distance indicator equipment, cameras, chaff or flare dispensers, and ECM jammers. The basic configuration and dimensions are as for the Talos anti-aircraft missile, described in an earlier entry (**1030.231**) in this volume.

DEVELOPMENT:

Work was started on the development contract in June 1972 and the last flight test in June 1974 was scheduled to complete the development programme. Of the eight targets covered by the contract, five were flown at the White Sands Missile Range and two at the Pacific Missile Range. All major test objectives were met, including a demonstration of cruise capability at less than 250 ft (76 m) for 20 nm (37 km).

The second flight model of the Talos missile-based LAST – Low Altitude Supersonic Target – vehicle photographed during trials at the US Army White Sands Missile Range

MANUFACTURER:
The Bendix Corporation, Aerospace Systems Division, 400 South Beiger Street, Mishawaka, Indiana 46544, USA.

1101.391
QUAIL (ADM-20C) DECOY MISSILE

DESCRIPTION:

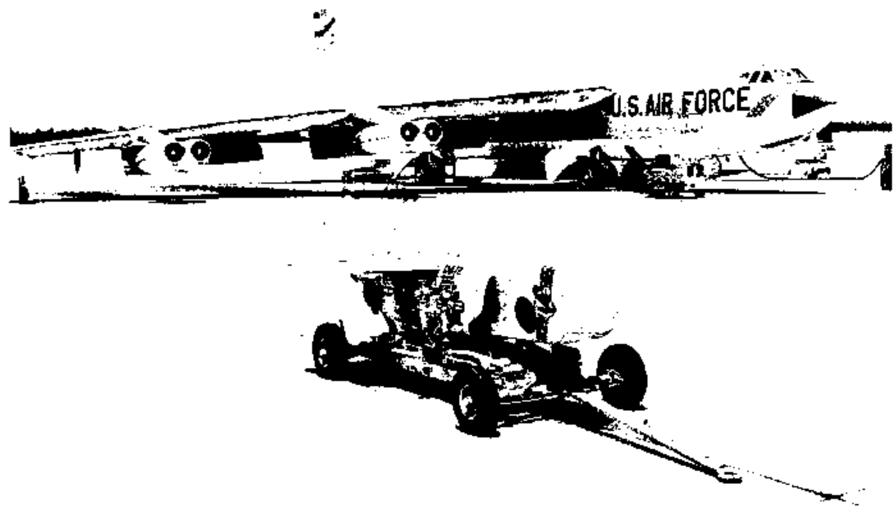
Formerly designated GAM-72, the Quail is a missile drone designed to afford USAF Strategic Air Command B-52 aircraft with defence against opposing forces by acting as a decoy. It is carried on special racks in the B-52 bomb bay, and after release it produces a radar signature similar to that of a B-52. By confusing enemy radar it assists penetration by the bombers themselves. Principal characteristics are: – length 304 cm, width (wings folded) 76 cm, height 103 cm, wing span 168 cm, weight 499 kg, speed over 960 khp, range over 400 km. It is powered by a general Electric J 85 turbojet motor, and guidance is by a gyro autopilot. The payload can include ECM equipment and a self-destruct explosive charge.

STATUS:

The ADM-2C is operational with USAF Strategic Air Command B-52 units. Production ceased in February 1961 and the last delivery was in May 1962.

MANUFACTURERS:

McDonnell Douglas Corporation, St. Louis, Missouri 63166, USA.



ADM-2C Quail decoy missile on loading trolley

1220.391
SCAD DECOY MISSILE (AGM-86A)

DESCRIPTION:

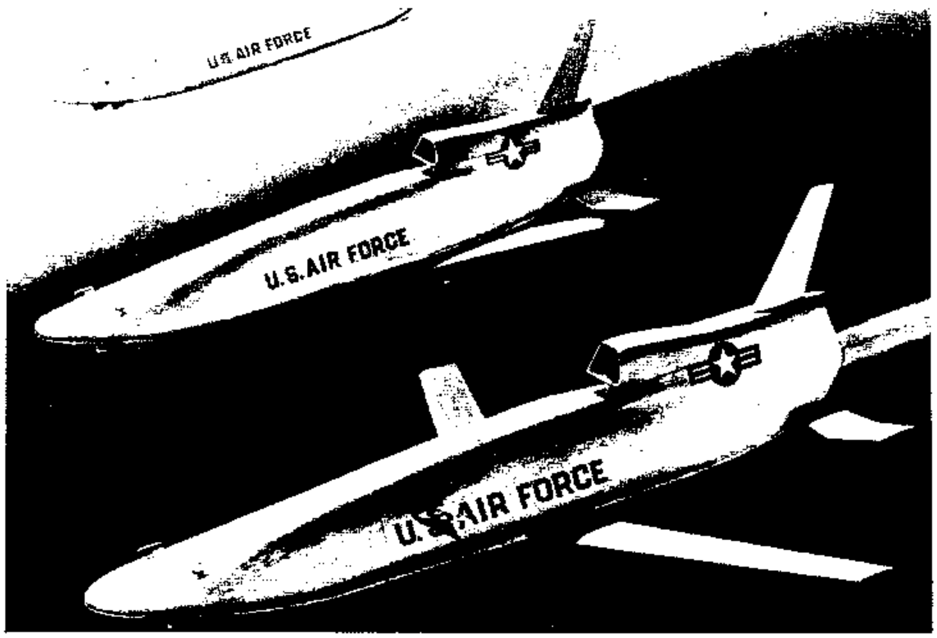
SCAD (Sub-Sonic Cruise Armed Decoy) was originated as a successor to Quail for B-52 aircraft and as a combined decoy/weapon for the B-1 strategic bomber. After several years of development, the American DoD decided in 1973 to halt further work on this project and to transfer the effort to the more recent ALCM (Air-Launched Cruise Missile) project (**1766.311**). The latter weapon is planned to have a number of common features with the US Navy's new SLCM (Submarine-Launched Cruise Missile) (**1759.411** and **1758.311**), among them being the air-breathing turbo-jet power unit. The USAF is expected to employ as much as possible of the technology developed for the SCAD programme in the ALCM.

Details of SCAD appear in the last edition of Jane's Weapon Systems.

STATUS:

SCAD advanced development was approved by the Deputy Secretary of Defense in July 1970, and in September of that year the Cornell Aeronautical Laboratory was awarded a $4.34 million contract for electronic warfare payload and credibility analysis studies.

Principal SCAD contractors named in 1972 were Boeing for the airframe, Litton for guidance and Philco-Ford for the decoy electronics. The project was cancelled by the DoD in 1973.



AGM-86A Subsonic Cruise Armed Decoy is shown with variable wing sweep and retracting canard control surfaces in this artist's impression

2521.391
BEECH CARDINAL (MQM-39A, MQM-61A)

DESCRIPTION:

The Beech Cardinal is a target drone used for ground-to-air and air-to-air missile system testing and crew training. Originally developed for the US Navy it has for several years been in use in many other countries. More than 2,000 have been built since production started in 1959.

LEADING PARTICULARS:

Power Plant: One McCulloch 125 C.V. engine driving a two blade propeller
Guidance: Radio command
Take-off: Rocket assisted by two JATO bottles for zero-length launches
Recovery: Parachute
Max level speed: 550 kmh
Service ceiling: 13,000 metres
Endurance: Over 1 hour at 7,600 metres
Special Features: Equipment can be carried to give radar returns appropriate to much larger aircraft and infra-red sources can also be carried.

Modified version can be used to tow a target. Strike panels can be fitted, with infra-red sources, to minimise damage from direct hits by homing missiles.

Smoke generators and/or navigation lights can be fitted for visual location

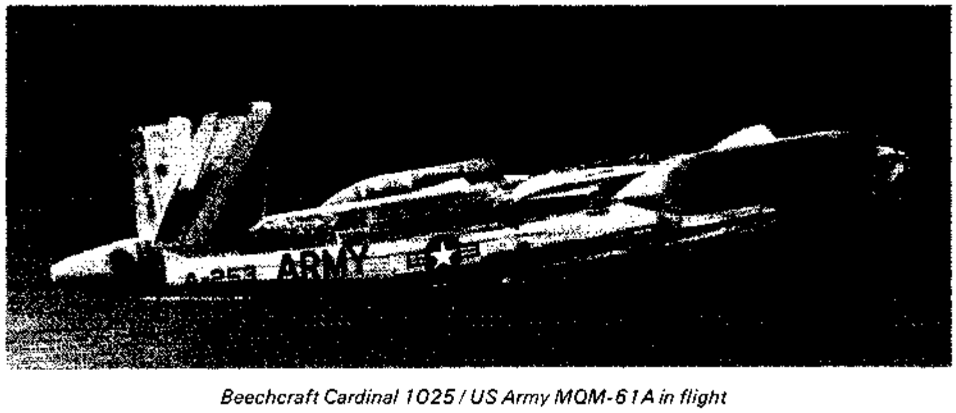
Babcock miss-distance indicator can be fitted.

STATUS:

The MQM-61A has been in use since 1958, and since then has been adopted by the US Navy and Army, and the Swiss, Spanish and German Armies. By 1974, 2,300 had been ordered and delivered.

MANUFACTURER:

Beech Aircraft Corporation, Wichita, Kansas 67201, USA.



Beechcraft Cardinal 1025 / US Army MQM-61A in flight

2522.391
BEECH MODEL 1019 (AQM-37A)

DESCRIPTION:

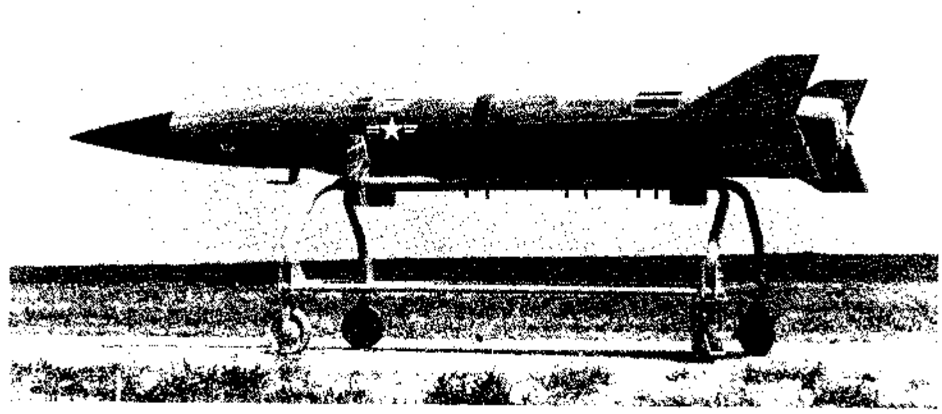
This is a non-recoverable, supersonic, air-launched missile target system designed to simulate invader aircraft and missile threats and to provide defence weapon system evaluation and crew training. The target provides both active and passive radar augmentation for radar acquisition and tracking; and a chemical flare is provided for infra-red homing. Two optical miss-distance systems are available.

LEADING PARTICULARS:

Power Plant: One Rocketdyne/AMF LR64 P-4 dual-chamber liquid-propellant rocket-engine
Guidance: Programmed
Launching: Air-launched
Recovery: Non-recoverable. Automatic destruct system operates at end of flight or in case of major failure. Command destruct standby system for added range safety
Operating speed: Mach 0.4 to Mach 3.0
Operating height: 300-24,500 metres
Endurance: 15 min
Special Features: Approx 0.04 cu m of space in nose section for optional scoring and augmentation systems. Target compatible with non-cooperative scoring systems such as the Babcock 800 B2

In addition to the AQM-37A models built for the US Services, four other variants have been announced:

MODEL 1072 (SHORT SD.2 STILETTO): Version for UK substantially re-engineered by Short Brothers & Harland to meet British requirements, including virtually complete replacement of the radio and radar systems and control system changes. Total of 55 ordered, of which the third batch, of 20 targets, were fitted by Beech with a single chamber rocket motor. The Stiletto is launched from a Canberra PR MK-3 aircraft. In a successful first test flight at Llanbedr on August 1, 1968, the drone was released at 55,000 feet (16,750 m) and flew for more than 28 nautical miles (52 km) at an average speed of Mach 1.4 before the flight was terminated by a commanded explosive destruct.



Beechcraft Model 1019 Missile Target (AQM-37A)

Principal modifications made by Shorts were the incorporation of a British EMI T44/1 telemetry system; provision of additional 15V flight break-up system (WREBUS); installation of radioactive miss-distance indicator (RAMDI), with associated radio link; introduction of Plessey IR 112A/IR 310 tele-command system with heading and turns command circuitry; modification to propulsion system to give Mach 2 performance at 60,000 feet (18,300 m); and changes in the radar augmentation system. The current Stiletto system consists of the basic target vehicle plus a number of optional mission kits which can be either installed by Shorts or delivered separately for customer installation.

MODEL 1088: Manufacturer's designation of five targets supplied to Italy. These are intended for air launch from F-104S aircraft of the Italian Air Force.

MODEL 1094: Designation of 15 targets ordered in mid-1973 by the French Air Forces. A follow-on quantity of 30 has been negotiated. Delivery of the first articles to begin in May 1974.

MODEL 1095: The UK Ministry of Defense has negotiated for the purchase of ten Model 1095 targets. This version has been modified to the specifications of the MOD and will be used for crew training exercises on the Hebrides Range.

STATUS:

The AQM-37A is in service with the USN (1962), USAF (1967), US Army (1968), UK (1966), Italian Air Force (1969), and French Air Force (1974). A successor HAST – High Altitude Supersonic Target – is under development. Flight tests of the production configuration began in late 1972. Earlier tests were carried out using a modified AQM-37A fitted with the United Technology Centre hybrid rocket which will be used in production models.

MANUFACTURER:

Beech Aircraft Corporation, Wichita 67201, Kansas.

1813.391
BEECH MODEL 1092

DESCRIPTION:

The Beechcraft Model 1092 is a pilotless, recoverable target drone designed for in-sight or out-of-sight control. Essentially, it is a jet-powered derivative of the proven Model 1025 piston-engined target vehicle (**2521.391**), and is claimed to have a cost-effectiveness better than any other system in its performance category. The configuration of the Model 1092 can be seen in the accompanying illustration.

LEADING PARTICULARS:

Power Plant: One Teledyne CAE 372-2 (J402-CA-400) turbojet engine, rated at 290 kg st. The engine can be throttled by remote command, permitting a very wide variety of mission profiles with endurances (depending upon mission speed and altitude) of up to several hours.
Launch and Recovery: Launchings utilise the zero-length procedure, with solid-propellant rocket motors providing the boost thrust. The target is recovered following completion of flight by a single-stage 14.6 m diameter parachute. The vehicle has flotation capability and may be recovered over land or water
Control and Guidance: Stabilisation and command control is by two-axis autopilot, with a Babcock digital command receiver/decoder providing the ground link
Dimensions: Wing span 3.68 m. Length overall 4.60 m. Body diameter 0.45 m
Weight: Max launching weight 454 kg
Performance: Max level speed 834 km/h. Ceiling 12,200 m

MANUFACTURER:

Beech Aircraft Corporation, Wichita, Kansas 67201, USA.

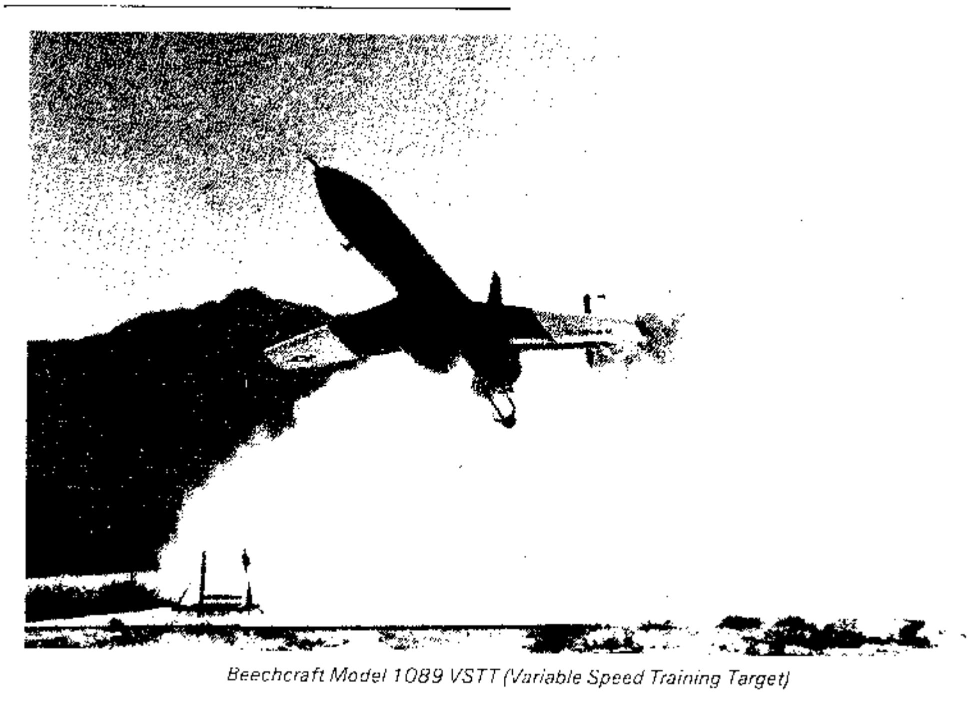
BEECH MODEL 1089 VSTT

DESCRIPTION:

Beech Aircraft Corporation is participating in a "price and performance" competition to design and develop a new Variable Speed Training Target (VSTT) for the US Army's Missile Command. The programme consists basically of the following three phases: (1) design and manufacture of hardware; (2) contractor flight tests; and (3) Army evaluation tests. The principal function of the VSTT will be to tow a variety of targets for missile training and evaluation. Two TA-8 radar augmentation targets or two TA-8 infra-red augmentation targets can be carried on each mission and towed separately as far as 1,500 m behind the VSTT.

The VSTT will serve as an aerial target for air defence systems such as Chaparral, Redeye, Hawk and Vulcan, and is expected to become the primary subsonic missile training target for the US Army. The VSTT will be capable of operating at altitudes from 90 m to 12,200 m and at speeds of up to 500 knots (936 km/h).

As of March 1974, twenty flights in the contractor development test programme and in the US Army evaluation programme were completed. In these flights high altitude, speed, flight control



Beechcraft Model 1089 VSTT (Variable Speed Training Target)

and towing capability have been demonstrated as well as operation of the recovery system. Recoveries are being made with minimal damage to the crushable, impact absorbing nose.

The Beech VSTT, shown in the accompanying illustration, is powered by a Teledyne CAE 372-2 turbojet engine of 290 kg st and carries 64 US gallons (242 litres) of fuel. It is launched from the ground with a JATO booster and has a drogue and main parachute command recovery system.

The modular design employed throughout the system provides for ease of fabrication and for economy in operation and maintenance. One unique design feature is the flat airfoil section of the wing and tail surfaces. The fuselage is cylindrical. Low cost bonded honeycomb is used for the immovable aero surfaces while the aero control surfaces are constructed of aluminium skins and filled with poured-in-place foam. Support equipment is both minimal and lightweight providing for transportability and deployment of the system. Checkout and launch equipment is packaged in two suitcase size containers.

The guidance and control system provides for both ground control and for preprogrammed flight. The flight control operator is provided with all pertinent flight information by radio link from sensors located in the vehicle and the operator can command vehicle manoeuvres as well as recovery. In flight the guidance and control system automatically stabilises about the roll, yaw, and pitch attitudes and provides altitude and velocity hold modes.

LEADING PARTICULARS:

Guidance: Radio command

Dimensions: Wing span 3.00 m. Length 5.13 m. Height 1.47 m. Body diameter 0.38 m

Areas: Wings (total projected) 2.52 m^2. Horizontal tail surfaces 0.79 m^2. Vertical tail surfaces 0.43 m^2

Weights: Launching weight (including booster) 460 kg. Usable fuel 173 kg

Performance: Endurance: more than 3 hours

MANUFACTURER:

Beech Aircraft Corporation, Wichita, Kansas 67201, USA.

1815.391
BEECH MODEL 1070 HAST

DESCRIPTION:

Beech Aircraft is continuing a development programme for the USAF Armament Laboratory at Eglin AFB, Florida, under contracts totalling $13 million, to provide a high-performance air-launched aerial target system for use by the three Services of the US Department of Defence. The HAST (High Altitude Supersonic Target) is a continuation of the former Sandpiper project, which concluded a successful flight test programme in 1968. A hybrid propulsion system and a command manoeuvring system were demonstrated in that flight test programme. In 1971 Beech received authority to build 12 flight test units of the HAST and 13 refurbishment kits, and delivery of the former began in 1972. A recovery system development programme utilising an inert HAST vehicle has been completed. This programme has proved the recovery system with both water and aerial retrieval of the vehicle. Captive flights have been completed and powered flights are scheduled at two month intervals. The target is intended initially to be carried by F101 Voodoo, F-4 Phantom, F-14 Tomcat and F-15 Eagle aircraft.

The flight performance envelope of the HAST covers a range from Mach 1.2 at 12,200 m to Mach 4.0 at 30,500 m. The target is designed to be air-launched at speeds of Mach 0.8 to 2.5. Manoeuvres of between 5g at 10,670 m and 1.15g at 27,400 m are to be performed. The vehicle is to be capable of performing "S" and 180° turns in the horizontal plane and altitude changes in the vertical plane. Manoeuvres can be preprogrammed or can be initiated via ground command radio link. Modular payloads with a wide variety of options will be available for accurate simulation of aircraft or missile threats. Payloads will include various radar and infra-red augmentation devices as well as a flare/chaff dispenser. Vector miss-distance scoring systems will also be included.

Beechcraft Model 1070 HAST (High Altitude Supersonic Target)

The modular recovery system has been developed as an optional feature for mid-air retrieval of HAST, or for land or water recovery. Refurbishment of recovered targets will permit their re-use.

LEADING PARTICULARS:

Guidance: Pre-programmed, with ground command interface

Dimensions: Wing span 1.02 m. Length 5.08 m. Height 0.66 m. Body diameter 0.33 m

Areas: Wings (total exposed) 0.97 m^2. Foreplanes (total exposed) 0.12 m^2. Stabilisers (each) 0.31 m^2

Volume: Payload volume 0.041 m^3

Weights: Launching weight 519 kg. Propellant 297 kg. Payload 38 kg

Performance: Endurance at Mach 3 – 5 min

MANUFACTURER:

Beech Aircraft Corporation, Wichita, Kansas 67201, USA.

2615.391
FIREBEE (BQM-34A/MQM-34A)

DESCRIPTION:

One of the best-known target drones in the world, the Teledyne Ryan Firebee has a history dating back to 1951. Development of the current version began in 1958, however, and various improvements have been added since the first production model of this version flew in 1960.

Firebee is a turbojet-powered remotely controlled drone used mainly for target purposes but with the capability of being used in a reconnaissance role (see following entries). Designation of the current standard version is BQM-34A: there is also a version known as MQM-34D used by the US Army, which has a longer burning rocket booster for ground launch and extended wings which enable it to take off at a loaded weight some 450 kg greater than the maximum for the BQM-34A.

LEADING PARTICULARS:

Power Plant: 722 kg thrust Continental J69-T-29 turbojet

Guidance: Radio control. Drone carries R425/ARW-59 (USAF) or AN/DRW-29 (USN) radio control receiver and A/A37G-3 flight control system

Launch: Air launch or ground launch with JATO rocket

Recovery: Parachute system deployed by remote command or in the event of loss of power, damage or system failure

Max level speed: 1,040 kmh at 2,000 metres

Max diving speed: Mach 0.95

Max cruising speed: 1,000 kmh at 15,000 metres at 800 kg AUW

Rate of climb: 4,875 metres/min at S/L

Operating height range: 15-18,300 metres

Endurance: 75 mins at 15,000 metres

Flotation time: 1 hour with 25% fuel

Special features: Adjustable TWT amplifiers for L, S, X and C-band radar signal enhancement. Increased manoeuvrability kit to give 5-6 g turn capability.

RALACS – Radar Altimeter Low Altitude Control System – available for precision low altitude flights at 15 metres altitude, over water or 30 metres over land

FIREBEE II (BMQ-34E)

Description:

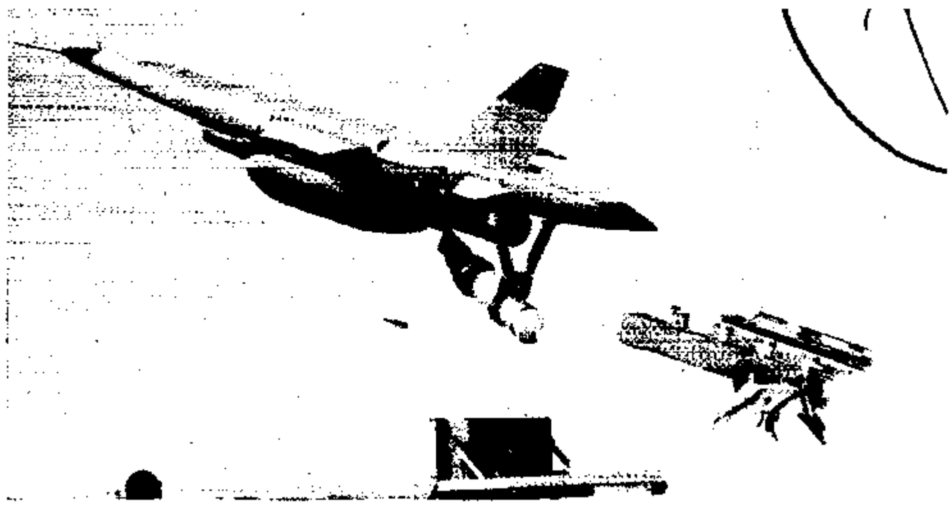
The Ryan Model 166 Firebee II is a supersonic target drone developed for the US Navy as an advanced version of the subsonic BQM-34A drone described above. The new drone is designed to provide aerial target presentations at around 15,000 metres altitude at supersonic dash speeds up to Mach 1.5 for a period of 10 minutes. With full fuel load, range time may be extended to 75 minutes. Among other improvements the new drone is designed to carry much more in the way of radar enhancement and tracking aids than its predecessor.

Leading Particulars:

Power Plant: 835 kg thrust Continental YJ69-T-6 turbojet engine

Guidance: Drone carries AN/DRW-29 radio control receiver and A/A37G-3 flight control system

Launch: Ground launch with JATO bottle



Firebee II supersonic target drone

Recovery: Similar to BQM-34A
Max Speed: Mach 1.5 at 18,000 metres
Operating height range: 15-15,250 metres
Endurance: 83 minutes total
Flotation time: 24 hours
Special equipment: AN/DLQ-1, -2 and -3 ECM equipment.
AN/USQ missile scoring system.
RALACS (see above).
X-band and C-band tracking beacons.
TWT radar augmentation for S- C- and X-band.
Solid-state radar augmentation for P-band.
Passive radar reflectors.
Dorsett TM-4-31A, telemetry system

MANUFACTURER:
Teledyne Ryan Aeronautical, San Diego, California, USA.

The British Aircraft Corporation concluded an agreement covering sales and manufacture in 1968. In 1970 BAC received a Ministry of Technology contract for a feasibility study relating to the operation of Firebee II in the Cardigan Bay missile range.

DC-130 drone launch aircraft carrying four Ryan Firebee target drones. Beneath left wing are two subsonic Firebee I (BQM-34A, Ryan Model 124), and under right wing are supersonic Firebee IIs (BQM-34E, Ryan Model 166)

1392.351
147 SERIES RECONNAISSANCE DRONES
DESCRIPTION:

The Teledyne Ryan Model 147 series of drones is an extensive one and comprises at least 21 different models which have been developed mostly in response to specific USAF reconnaissance requirements associated with American operations in S E Asia. Further details of these reconnaissance and surveillance programmes appear in the Reconnaissance Systems section of this book, which follows.

Although based on the successful Model 124 Firebee target drone airframe, and therefore bearing a close resemblance to it, the various Model 147 drones and RPVs individually differ widely in a number of characteristics and are generally both larger and heavier than the target models. The adjacent table of dimensions for the principal Model 147 versions indicates the range of these variations and the other illustrations in this section illustrate the detail differences in configuration which exist. Either one of three Teledyne Continental CAE J-69 engines is used to power Model 147 RPVs, the 1,700 lb (770 kg) st T-29, 1,920 lb (870 kg) T-41A, or 2,700 lb (910 kg) J100-CA-100.

The manufacturer's designations include suffix letters to denote the various models, and the USAF designations adopt the same procedure (but different letters); and, to the extent permitted by security considerations, the following list gives details of individual models and their operational roles.

Model 147A/C: Probably prototype low/medium level photo-reconnaissance version. Built under USAF Big Safari programme, and based on Firebee I drone.
Model 147B: Probably prototype high level photo-reconnaissance version. Larger than A/C models.
Model 147D: Probably developed low/medium level reconnaissance model
Model 147E: Probably developed high level reconnaissance version.
Model 147G/J: Two 147G drones were modified in 1972/3 for use as test vehicles in the FDL-23 project undertaken by the USAF Flight Dynamics Laboratory to study control techniques and applications of RPVs. Also known as Red Baron, this project includes an examination of the uses of RPVs in a possible air-superiority role. The modified 147Gs have the normal Lear Siegler drone autopilot but with yaw axis con-

Four versions of the Teledyne Ryan Aeronautical Model 147 drone, with DC-130A launch and control aircraft being prepared for flight

Model 147TE drone awaiting loading. The aircraft in the background, already with two more drones beneath its wings, is a specially-equipped DC-130E launch and control aircraft. Chin radome houses antenna for UPQ-3 microwave guidance and control system trol and three-axis proportional control facilities added. In the nose of the 147G is a Cohu 945 line TV camera, equipped with a 10:1 remotely operated zoom lens, the video from which is telemetered back to a remote control position on the ground. The latter is equipped with a large-screen display, which in conjunction with flight data telemetered from the RPV, enables the ground pilot to 'fly' the drone. The ground station is also equipped with tracking radar to provide accurate navigational information. The radar used is a C-band FPS-16 equipment which is also used to provide the necessary data link command facilities for piloting the 147G.

Model 147H (AQM-34N): Medium altitude reconnaissance model. Entered SAC service about 1968.

Model 147NA (AQM-34G): Low altitude version with wing pod mounting points, used for electronic warfare operations. Probable dual recce/jamming capability. Can carry ALE-2 chaff dispenser pods.

Model 147NC (AQM-34H): Low altitude version with wing pod mounting points, used for electronic warfare operations and with photo-reconnaissance capability. Initially developed for use in Vietnam as an ECM precursor vehicle in support of air strike forces under the Combat Angel programme, but not operationally deployed in the SE Asia theatre. AQM-34H drones are now operational with the USAF 11th Tactical Drone Squadron. A variety of EW pods can be carried, for both active and passive ECM missions, the Model 147NC being able to carry either two ALE-2 or ALE-38 chaff dispensers, or ALQ-71 or QRC-335 noise jammer pods. The drone is equipped with a doppler navigator system and provision for a programmed flight path.

Model 147NC(M-1) (AQM-34J): This is similar to the Model 147NC (above) but without the wing pod mounting points. It is used by the USAF 11th Tactical Drone Squadron for low altitude photo-reconnaissance and training missions.

Model 147NP: Low/medium altitude version, probably for day reconnaissance.

Model 147NQ: Similar to Model 147NP.

Model 147NRE: Low/medium altitude mode. Probably for night reconnaissance missions.

Model 147NX: Low/medium altitude model. Probably for experimental night reconnaissance role.

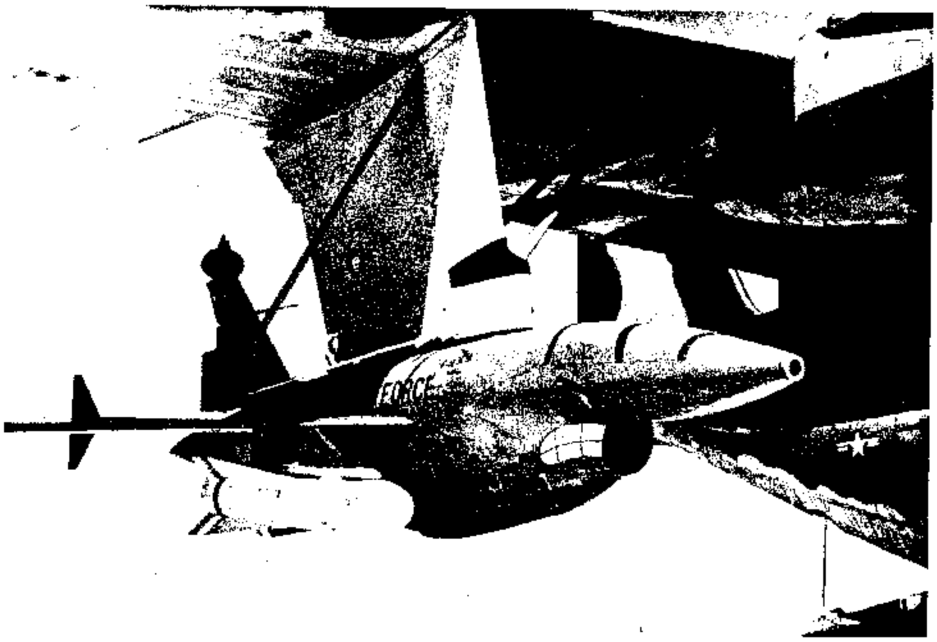
Model 147SA/SB: Day reconnaissance version for low/medium altitude operations.

Model 147SC (AQM-34L): Low level photo-reconnaissance version. Downward looking camera carried in extended nose. Equipped with doppler navigator, and provision for command guidance. Used by USAF Strategic Air Command 100th Strategic Reconnaissance Wing in Korea under Compass Bin programme. Also deployed with 11th Tactical Drone Squadron, USAF, from 1969 onward.

Model 147SD (AQM-34M): Low level reconnaissance model. Used in Compass Bin programme (above). The AQM-34M was modified by the addition of a Loran navigation system to improve track keeping and navigational accuracy, modified drones bearing the USAF designation AQM-34M(L). Teledyne Ryan also produced an Extended Range version of the Model 147SD with hard point mounts for wing tanks. It is possible that these mounts could also be used to carry either active or passive ECM pods as an alternative to extra fuel. As used in the Far East, the AQM-34M was employed also for leaflet dropping in a programme code-named Litterbug.

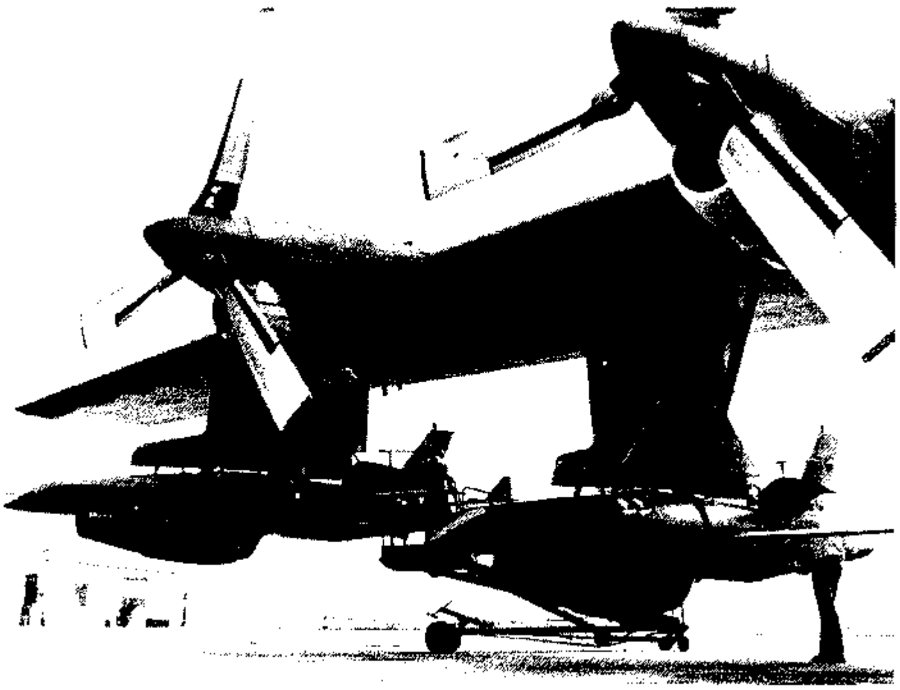
Model 147SRE (AQM-34K): Low/medium altitude night reconnaissance version. Deployed with 11th Tactical Drone Squadron, USAF.

Model 147T (AQM-34P): Medium altitude night surveillance version, probably equipped for infra-red linescan reconnaissance and Elint operations.



BGM-34A Ryan Model 234 drone armed with Maverick TV-guided missile for offensive drone operation trials

Recovery by helicopter of Model 147TF drone after a mission



Model 147 drones on DC 130A launch and recovery aircraft being prepared for flight

Model 147TE (AQM-34Q): Medium/high altitude night Sigint and Elint model, with extended range capability by means of wing tanks and with provision for command guidance and data telemetry. Used in Combat Dawn programme in Vietnam. Flight durations of 8 to 12 hours have been reported.

Model 147TF (AQM-34R): Similar to Model 147TE (above) and employed on same missions, but probably with differing payload to suit other frequency bands and types of signal gathering missions.

Update (YAQM-34U): Under this programme a number of Model 147SC low-level reconnaissance drones were equipped with improved avionics and flight control equipment to improve navigational accuracies and thereby enhance the operational performance. The programme also included adapting the Model 147SC drone to carry pods from which battlefield monitoring sensors for the Igloo White surveillance and monitoring system (**1397.151**) could be dispensed. The main navigational aid provided in the Update package is a Loran C/D equipment (which has the advantage over the doppler navigator used in some other Model 147 drones of not radiating RF energy which could reveal the drone's presence to an enemy), with the TERCOM (Terrain Comparison) system available as an alternative for areas lacking Loran coverage. The latter is based on a digital comparison of the changes in terrain height encountered as the drone over-flies the ground with a stored version of the planned flight profile. Another item of the Update package which is relevant to this as well as other aspects of operation is a Honeywell APN-194 radar altimeter. The first Update flight test was made in March 1973, about one year after commencement of the programme which was scheduled to run for about 12 months.

OPERATION:

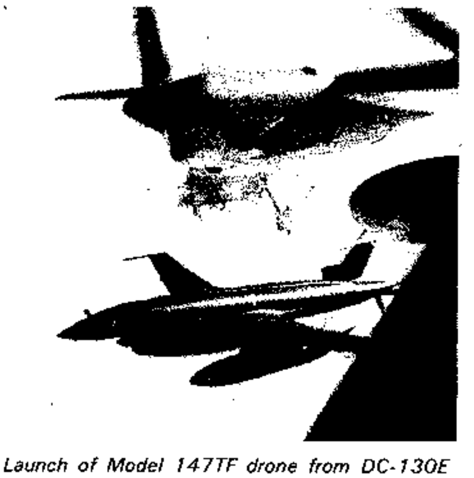
Model 147 drones have been developed for the following broad categories of operational roles:

Photographic reconnaissance.
Infra-red linescan reconnaissance.
Sigint collection.
Elint collection.
Active ECM
Passive ECM.
Sensor seeding.

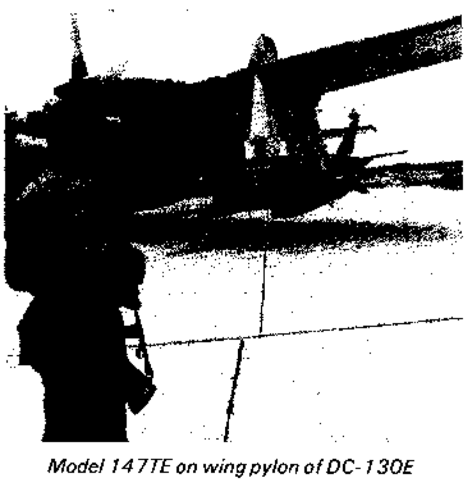
In some cases two or more of these roles may combine on a single vehicle, and the number of possible permutations is further increased by other operational variables such as low, medium or high altitude, day or night missions, long or short range, and whether data is recorded on board the drone or relayed back to an airborne or ground-based station as it is gathered. Another important option is the type of control procedure adopted, which can range from a completely self-contained and pre-programmed mission profile to the RPV technique of remotely piloting the vehicle and controlling the sensor functioning from a ground-based or airborne control station. The differing operating circumstances bring their own particular requirements for navigation and other drone sub-systems, which results in a relatively wide variation in equipment. For example, a high-level, long-range Elint drone would require a navigation and guidance system that gave relatively modest positional accuracy over a long-term, while a low-level photo-reconnaissance drone would require the best navigational accuracy obtainable to ensure that the desired targets are overflown and that data gathered can be accurately correlated. In a similar way, the nature of the operational role will have a bearing on the quality of flight stabilisation that is provided.

A typical navigation and guidance package comprises an air data computer and its related sensors, a doppler navigator, twin-gyro platform and a programmer unit. In addition, provision is made for varying degrees of manual over-ride for flight corrections or mission changes, in one instance the necessary two-way data link facilities for this are provided by means of a transponder (APQ-25 or APQ-26) on the drone working in conjunction with Univac UPQ-3 microwave guidance and control system. This provides for monitoring of on-board drone flight parameters, radar tracking of the vehicle and for command guidance facilities. As mentioned above, the Update programme is concerned with the provision of more sophisticated navigation equipment and other projects are concerned with the means of providing more elaborate and comprehensive guidance facilities, including the ability to permit multiple RPV operations.

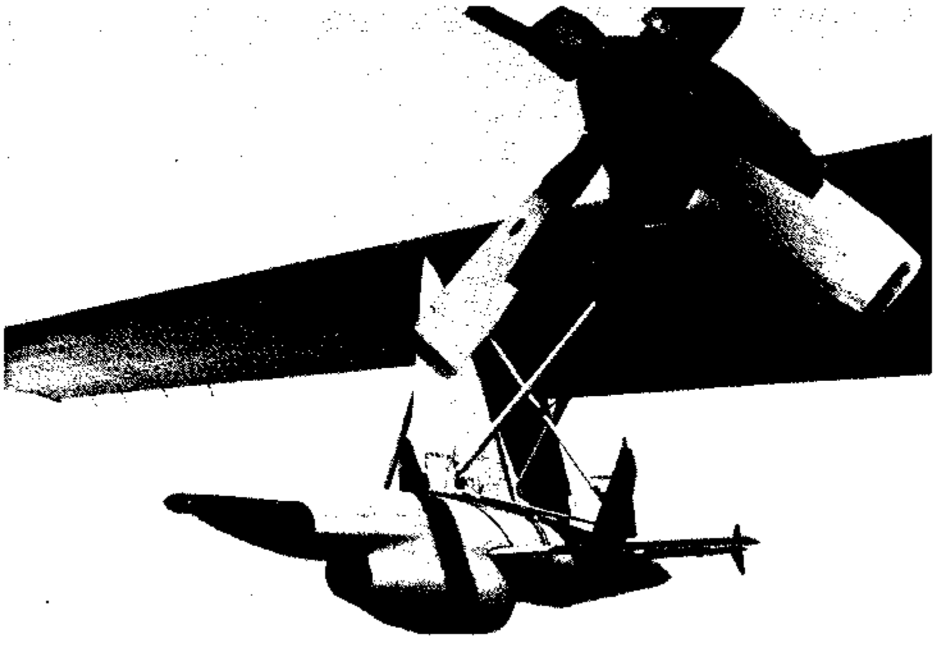
A launching from beneath the wings of specially modified DC-130 aircraft is the normal technique, these aircraft being equipped with the UPQ-3



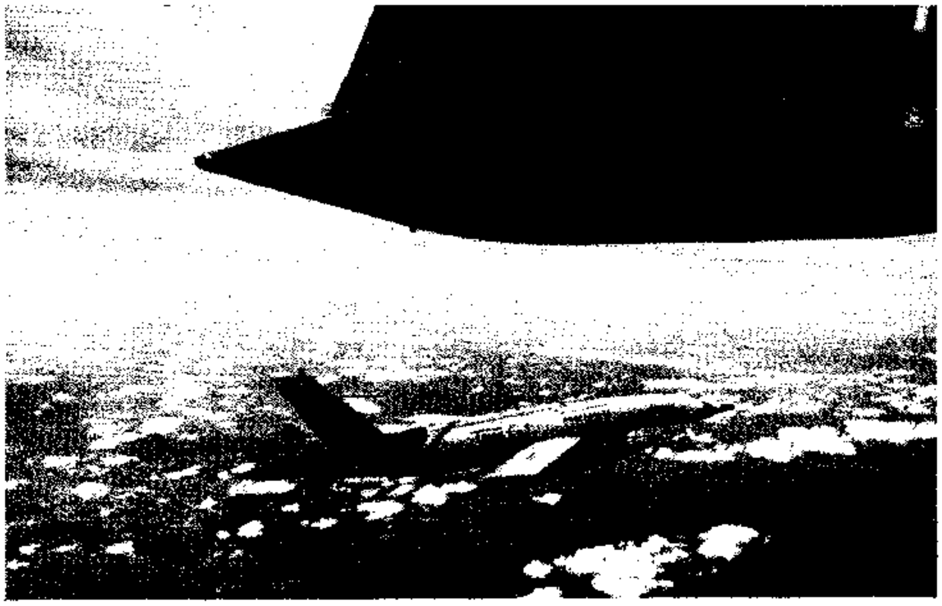
Launch of Model 147TF drone from DC-130E launch and control aircraft



Model 147TE on wing pylon of DC-130E



Another version of Model 147 drone. Note nose sensor package



Start of mission for Ryan Model 147SC drone system to permit their operation as airborne guidance and control stations. The system allows for control to be passed to a similar station on the ground, provided line-of-sight radio contact can be maintained with the drone (at the time(s) that it is necessary to either exercise control over the drone or receive data from it). A mission is generally terminated by shut-down of the drone engine, deployment of drogue and support parachutes, dumping of remaining fuel, and mid-air recovery by specially equipped CH-3 helicopter.

STATUS:

Reconnaissance drones, mostly of the Ryan Model 147 family, carried out a major part of the SE Asia photo-reconnaissance duties since their introduction in that theatre nine or ten years ago. They have also performed many other electronic intelligence missions and then undertook both active and passive ECM duties. Reconnaissance missions of less publicised nature have been carried out at various times in other parts of the world. Three USAF Commands operate the DC-130 drone launch and control aircraft: Tactical Air Command, with the 11th Drone Squadron at Davis-Monthan AFB, Arizona; Strategic Air Command, with the 100th Strategic Reconnaissance Wing operating Far East-based units; and Air Force Systems Command, 6514th Test Squadron, now based at a special facility at Hill AFB, Utah having moved from Edwards AFB in the latter part of 1973. The total number of DC-130s operated is relatively small but it is planned to increase their number by seven or eight in the course of the next two or three years. The Fiscal Year 1975 Defence Budget also envisaged the procurement of another 50 drones.

Future developments, in addition to those outlined above, include the use of high-altitude drones as relays for the data-relay function between data collecting drones and the base station, and improvements in recovery techniques. Others are related to the anticipated counter-measures which are likely to be encountered as the use of drones and RPVs increases and ensuring the necessary security of command and data links. Connected with the progression from drones towards remotely piloted vehicles are studies of the best techniques of effecting control, including the human factors problems involved.

Model 147SC reconnaissance drone on carrier DC-130 aircraft

1393.351
MODEL 154 (AQM-91A) FIREFLY RECONNAISSANCE DRONE

DESCRIPTION:

The Teledyne Ryan Model 154 Firefly drone has been designed for high altitude reconnaissance missions over hostile territory, and certain of its design features are stated to have been incorporated with the specific objective of ensuring high survival characteristics. They include shape and construction methods to achieve a low radar cross-section, and minimum infra-red emission from the J97 turbojet power unit.

The USAF designation is AQM-91A.

A more sophisticated navigational system than that of the 147 series of drones (Entry No. **1392.351**) is believed to be fitted, and this probably includes an inertial platform, doppler navigator, and a digital computer. A transponder for use with the Univac UPQ-3 microwave command guidance system to assist recovery by parent aircraft or ground station is also fitted. Retrieval is by means of a multi-parachute system and mid-air collection.

The sensor payload includes the Itek KA-80A optical bar panoramic camera.

STATUS:

US reports claim that the 154 Firefly has, as yet, been produced in small quantities only, probably less than 50. No details of operational use have been obtained.

MANUFACTURER:

Teledyne Ryan Aeronautical, San Diego, California, USA.

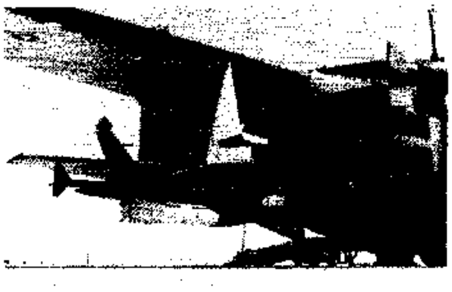
1818.311
MODEL 234 (BGM-34A/B) GROUND ATTACK DRONES

DESCRIPTION:

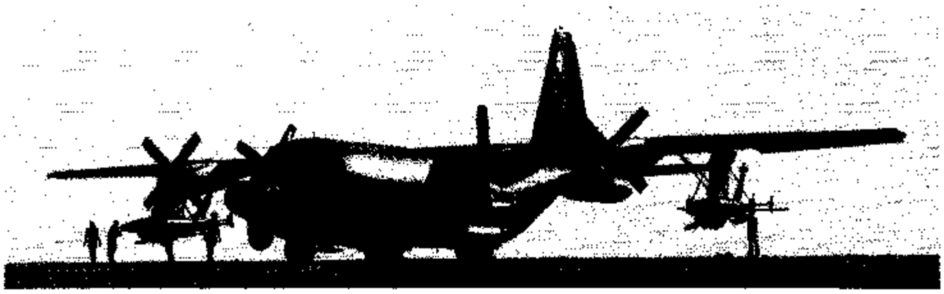
The designations BGM-34A and BGM-34B have been allocated to two more versions of the prolific Teledyne Ryan Firebee family of drones and RPVs, in this case specially adapted for the evaluation of the capability for the delivery of missiles and bombs in the ground defence suppression role. As can be seen from the table of Teledyne Ryan drones, the BGM-34B is longer and almost 200 kg heavier than the BGM-34A.

A batch of eight of the latter type were delivered to the USAF in the 1972-3 period, these being equipped with a nose-mounted TV camera, the video from which was telemetered back to the remote pilot in the DC-130 parent aircraft via the UPQ-3 microwave link which is standard for many of the Model 147 reconnaissance drones and RPVs. Maverick (**1098.311**), Shrike (**1102.311**), and HOBO electro-optically guided bombs (**1597.311**) were carried and launched in a series of tests directed at the study of RPVs for daylight defence suppression operations. In one mode of operation, the drone camera is used by the operator to locate and identify the target, whereupon this information is used to direct the camera of the Maverick's homing system onto the target for lock-on. Another technique for use against radar targets is for the radiation homing head of the Shrike to perform target identification and designation for the Maverick camera. The

BGM-34A RPV beneath wing of DC-130-E launch and control aircraft. RPV has Shrike anti-radar missile under right wing and Mk IV retarded bomb under left wing



BGM-34A RPV in USAF defence suppression evaluation trials has Maverick TV-homing missile on wing pylon



USAF DC-130E launch aircraft ready for BGM-34A test mission in defence suppression evaluation programme. RPVs have Shrike missiles and Mk IV bombs on board

Shrike could then be launched but if it failed to hit the target (through shut-down of the radar, for example), the Maverick could be launched to seek the same target by electro-optical homing.

The BGM-34B version was introduced in February 1973 and apparently exists in several versions. It is intended to extend the test and evaluation work initiated with the BGM-34A aircraft which preceded it. One important addition to the missions studied was that of night operations and laser target designation, or marking facilities. Two BGM-34Bs have been fitted with a smaller, lightened version of the Philco-Ford Pave Knife low-light level TV/laser target marker system, in this case being installed in the nose of the drone instead of the original pod housing. The laser target marker would permit the direction of laser-homing bombs carried either by the marker RPV or by stand-off aircraft or other drones. To provide the necessary additional data link capacity for multiple vehicle operation which is implicit in this concept, Sperry Univac has carried out modifications to the existing UPQ-3 link system as well as work on alternative systems, and RCA and other electronics concerns are also active in the area of multiple RPV control.

BGM-34B RPV for strike weapons delivery was rolled out by Teledyne Ryan on February 9, 1973

DC-130 RPV launch aircraft carrying BGM-34 loaded with HOBO and Mk IV bomb

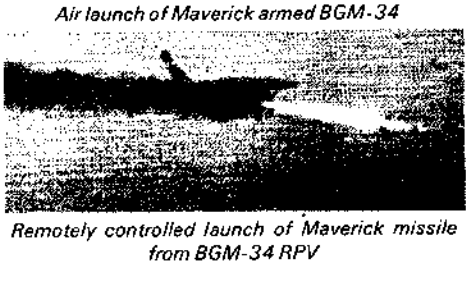
Air launch of Maverick armed BGM-34



Remotely controlled launch of Maverick missile from BGM-34 RPV

Loading HOBO electro-optically guided bomb onto wing of BGM-34A RPV for tests

Other sensors and other weapons are likely to be tried in the course of the BGM-34 studies which are expected to run for a considerable period as this important development is carefully assessed in greater depth than was always possible before American disengagement from Vietnam.

MODEL 235 (YQM-98A) COMPASS COPE R DRONE

DESCRIPTION:

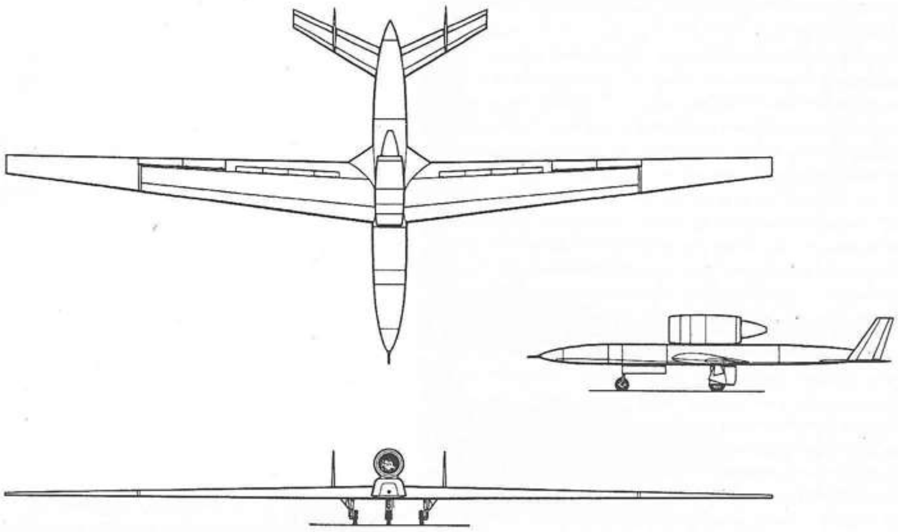
The Model 235 is the Teledyne Ryan entry in response to the USAF call for two prototypes of a new high-altitude, long endurance RPV under the Compass Cope reconnaissance programme (**1504.351**). The 'R' in the designation Compass Cope R denotes Ryan to distinguish between the competing model produced by Boeing as Compass Cope B (YQM-94A) (**1817.351**).

The configuration of the Model 235 is shown in the adjacent illustrations and the main characteristics are as follows.

LEADING PARTICULARS:

Power Plant: One Garrett AiResearch ATF-3 (XF104-GA-100) turbofan of 1833 kg st
Length: 11.4 metres
Span: 24.75 metres
Diameter: 0.82 metre
Max T/O Weight: 6,486 kg
Mission Payload: 317 kg
Cruising Speed: Subsonic

Operationally, the Compass Cope programme is intended as a follow-on and an extension of the



General arrangement drawing of Teledyne Ryan Model 235 (YQM-98A) Compass Cope R drone

One of the two YQM-98A Compass Cope R prototypes nearing completion

Over-fuselage mounting for Garrett AiResearch ATF-3 turbofan engine is seen in this view of Compass Cope R drone

Roll out ceremony for both Compass Cope R prototypes in January 1974 earlier Compass Dawn monitoring and surveillance programme carried out in SE Asia. Where the latter was principally concerned with Sigint and Comint operations, the roles envisaged for Compass Cope vehicles includes these functions and others such as battlefield reconnaissance, TOA/DME (Time-of-Arrival/Distance Measuring Equipment) missions, communications relay, ocean surveillance, atmospheric sampling, and photo-reconnaissance. Operating altitudes of up to 23,000 metres have been mentioned and mission durations of as much as 30 hours. These, and other, considerations have led to a different form of launch and recovery procedure from the normal air launch and recovery techniques employed in Model 147 operations, and it is planned to have the Compass Cope drones operate from runways like a conventional aircraft.

DEVELOPMENT:

The Teledyne Ryan Model 235 was developed under a cost-plus-fixed-fee USAF contract awarded on June 13, 1972, and in its design experience gained with the Model 154 was applied. Both the two prototypes called for under the contract were completed by December 1973 and were formally rolled out on January 4, 1974. They could have been ready to start flight tests in the following month but Congressional cuts in Compass Cope funds imposed a delay.

STATUS:

The entire Compass Cope programme is the subject of some uncertainty, partially as a result of there being no US arm able or willing to commit itself to a firm procurement requirement for the production version, but this is expected to be reflected only as variations in the pace of the project rather than outright cancellation.

MANUFACTURER:

Teledyne Ryan Aeronautical, San Diego, California 92112, USA.

1817.351

COMPASS COPE B DRONE (YQM-94-A)

DESCRIPTION:

The YQM-94A, with the competing Teledyne Ryan YQM-98A (**1816.351**), is under consideration as the high-altitude, long endurance vehicle required for the Compass Cope reconnaissance and surveillance project. To differentiate between the two models they are referred to as Compass Cope R and B, respectively to denote Ryan and Boeing, the manufacturers concerned. Similar contracts were awarded to both companies, (that to Boeing having been placed about a year before Teledyne Ryan's) and called for the production of two prototypes. The main characteristics of the Boeing YQM-94A are given below.

LEADING PARTICULARS:

Power Plant: One General Electric J97-GE-100 turbojet rated at 2,390 kg st. Other power plants have been considered
Length: 12.8 metres
Span: 24.43 metres
Max T/O Weight: 5,897 kg (approx)
Mission Payload: 317 kg
Cruising Speed: Mach 0.5 to 0.6 at 15,000 to 21,000 m

A retractable tricycle landing gear is fitted and conventional runway take-off and landing techniques will be used instead of the air launch and recovery system which is normal for most current drone operations. Details of envisaged operational roles are given in the entry for the YQM-94A (**1816.351**, above) and in that for Compass Programmes (**1504.351**) in the following section of this volume.

DEVELOPMENT:

Design studies were started by Boeing in late 1970, followed by the award of a USAF prototype contract in July 1971. First of the two prototypes ordered was rolled out in late November 1972. This was delivered to the USAF in February 1973, and it was planned that flight tests should be carried out by the USAF 6510th Test Squadron at Edwards AFB, California. However a crash which occurred on August 4th destroyed the prototype YQM-94A.

STATUS:

The entire Compass Cope programme is the subject of some uncertainty, partially as a result of there being no branch of the US Forces able or willing to commit itself to a firm production and procurement programme, and also due to reductions in funding. However, complete abandonment is unlikely.

MANUFACTURER:

Boeing Aerospace Company, Seattle, Washington 98124, USA.

1538.351

L450F XQM-93A RECONNAISSANCE DRONE

DESCRIPTION:

The L450F is a single-engine turboprop aircraft developed and equipped for medium altitude, long range strategic reconnaissance missions. It also may be used for certain tactical functions. The main characteristics of the aircraft are: wingspan 17.37 m, length 8.84 m, gross weight 2,086 kg, payload 320 kg, endurance 24.30 hours, cruise speed 165 km/hr.

Two L450F aircraft were funded by the USAF for flight trials and evaluation, and in April 1972 it was reported that one of them had successfully met USAF endurance and altitude requirements. The possibility that a batch of 12 L450Fs might be purchased for use by the USAF in the Compass Dwell signals intelligence gathering programme was mentioned late in 1971. In the event, neither the L450 nor the competing Martin Marietta Model 845A was put into production.

MANUFACTURER:

LTV Electrosystems, Inc., Greenville, Texas, USA.

1539.351

BEECH QU-22A/B BONANZA DRONE

DESCRIPTION:

The QU-22 is a modified version of the Beech Bonanza light aircraft, equipped for pilotless operation in a variety of battle area roles. A total of six aircraft were converted to QU-22A standard and 27 to QU-22B standard. Additional equipment includes electrical generating facilities with increased capacity to power sensor equipment, drone stabilisation and control systems, command equipment, transponders, data relay, and navigation sub-systems. The QU-22 was used in the Pave Eagle Programme (Entry No. **1533.311**) as a relay aircraft for data gathered by Igloo White (Entry No. **1397.151**) ground censors. A number of QU-22Bs were modified for use as remote controlled Forward Air Control (FAC) aircraft. After losses in SE Asia, the remaining aircraft of this type were withdrawn from service and put into storage.

2638.391

GYRODYNE QH-50D DRONE HELICOPTER

DESCRIPTION:

The QH-50D is the final production version of a series of drone helicopters that Gyrodyne produced while working on a US Navy contract, placed in 1958, for development of a specialised drone helicopter as the airline component of the DASH (Drone Anti-Submarine Helicopter) weapon system.

The QH-50D drone is powered by a Boeing T50-BO-12 shaft-turbine and is capable of carrying a weapon load of either two Mk 44 torpedoes or one Mk 46 torpedo.

Max speed: About 150 kmh

Speed for max range: About 150 kmh
Speed for max endurance: 100 kmh
Max rate of climb: 856 metres/min at S/L
Vertical rate of climb: 700 metres/min at S/L
Service ceiling: 4,875 metres
Max range, 10% fuel reserve: 227 km
Max endurance, 10% fuel reserve: 1 hr 43 min
Combat radius: 87 km

STATUS:

The QH-50D was considered for possible use in a number of Advanced Research Projects Agency programmes, including Night Gazelle, Night Panther, and Blow Low. The USAF has also investigated a number of armed roles for this platform. Evaluation trials have involved the inclusion of laser target designators, radar, and low light level TV in the payload. The DASH programme is no longer active.

MANUFACTURER:

Gyrodyne Company of America Inc., St. James, Long Island, N.Y.

2732.391
NORTHROP NV-105 CHUKAR

DESCRIPTION:

The Chukar is a lightweight target drone designed for anti-aircraft gunnery, surface-to-air missile and air-to-air missile training and weapon systems evaluation. Radio-controlled it is turbojet powered and is recoverable.

LEADING PARTICULARS:

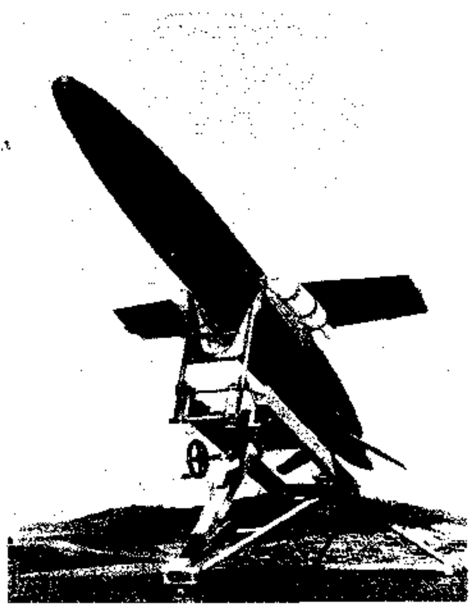
Power Plant: Williams Research Corporation WR24-6 turbojet, 2 JATO rockets for launching
Guidance: Radio control, automatic stabilisation and altitude hold
Launch: Rocket-assisted from zero-length launcher
Recovery: Parachute system operating on ground command or automatically on loss of power or system failure
Max level speed: 760 kmh at S/L; 815 kmh at 6,000 metres
Econ. cruising speed: 390 kmh at S/L
Rate of climb: 2,000 metres/min at S/L
Range: 300-450 km according to speed and height

STATUS:

The supply of a number of Chukar drones to Israel for non-target uses was reported in 1971.

MANUFACTURER:

Northrop Corporation, Ventura Division, Newbury Park, California 91320, USA.



MQM-74A Chukar gunnery target drone

1822.391
NORTHROP NV-123 VSTT (VARIABLE SPEED TRAINING TARGET)

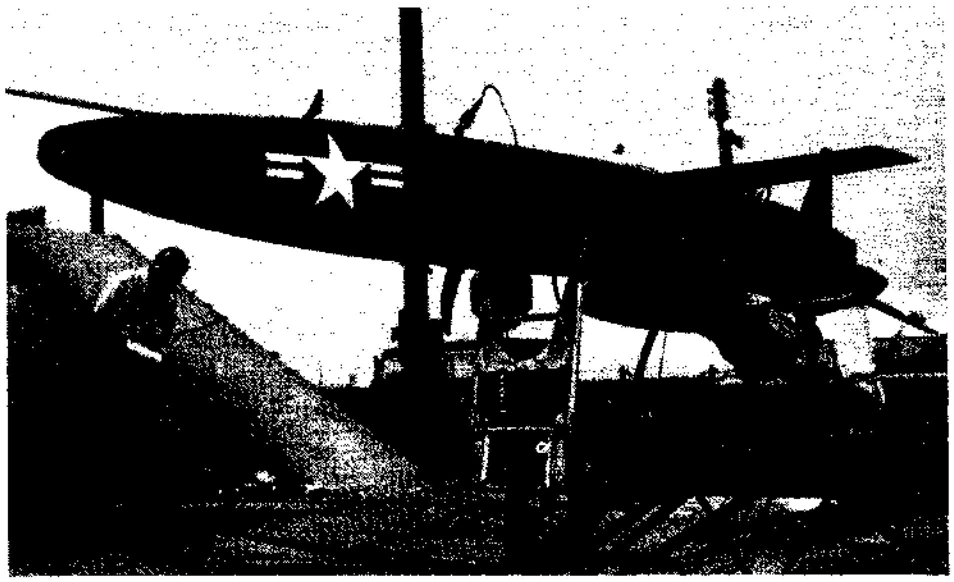
DESCRIPTION:

The NV-123 is Northrop's entry in the competition to provide the Variable Speed Training Target drone in response to the US Army requirement for training the crews of weapon systems such as Hawk, Redeye, and Chaparral in engaging high-performance air targets. The competing vehicle is one by Beech, described in Entry No. **1814.391**, which also gives more information about the operational requirement.

The Northrop NV-123 bears a close resemblance to the MQM-74C Chukar II target drone (**2732.391**).

LEADING CHARACTERISTICS:

Power Plant: Williams Research Corporation WR24-17 turbojet engine rated at 90 kg st. Single solid-propellant rocket booster motor for launch
Launch: Rocket assisted from zero-length ground launcher
Recovery: Parachute
Length: 3.8 metres
Diameter: 0.36 metres
Span: 1.7 metres
Launch Weight: 175 to 235 kg, depending on payload
Sea Level Speed: 450 to 1,050 km/h, variable
Altitude: 100 to 13,000 m
Duration: 2-3 hours



Bendix LAST (Low-Altitude Supersonic Target) prior to test launch at White Sands Missile Range

STATUS:

First flight of the NV-123 was made in early 1974 and a decision on which of the competing VSTT vehicles is to be put into production was due to be taken later in 1974 following test and evaluation flights.

MANUFACTURER:

Northrop Corporation, Ventura Division, Newbury Park, California 91320, USA.

1819.391
PQM-102 TARGET DRONE

DESCRIPTION:

In March 1974 it was announced that the USAF was about to make its first purchase of 22 F-102 Delta Dagger interceptor aircraft converted for use as unmanned target drones, in which form they bear the designation PQM-102. One of the main functions of this new class of target drone is for the testing and evaluation under realistic conditions of the latest types of air-to-air weapons and the new generation of fighter aircraft. There are already F-102s which have been withdrawn from front-line service and by 1975-6 it is planned to withdraw the remainder from USAF service; the PQM-102 inventory will be established from this source.

The USAF plans to build up a force of up to 132 of these drones at an annual rate of 22. Although classified as drones, the PQM-102 qualifies for the USAF RPV definition. A pilot sitting in a van at the end of the runway will carry out the preflight checks remotely and then 'fly' the aircraft off the ground and clear of the airfield area for handing over to the range radar mission controllers. If the drone survives the mission, the procedure will be carried out in reverse to recover the target vehicle.

DEVELOPMENT:

Sperry was awarded a $5.5-million contract in Spring 1973 for the conversion of an initial batch of six Convair F-102 aircraft for the target drone mission. Of the six, two retained the manual pilot facilities, these two models being designated QF-102; the other four were configured for full unmanned operation.

1820.351
RPAODS (REMOTELY-PILOTED AERIAL OBSERVATION/DESIGNATION SYSTEM)

DESCRIPTION:

This is a joint US Army/ARPA (Advanced Research Projects Agency) programme which has been in progress since 1972-73 with the objective of developing lightweight, low cost tactical RPV systems with day and night surveillance sensors and laser target designation capabilities. It is expected to result in vehicles that weigh in the region of 16 kg, cost less than $10,000 in quantity and have the capability of acquiring tactical information at ranges up to 80 km from their launch point.

In the interests of cost limitation the prospect of using vehicles similar to model radio-controlled aircraft is receiving a high proportion of the total effort but more exotic elaborations on this theme also are under examination. Many of the leading US defence contractors have made their own studies, proposals, and/or experimental prototypes, some of which have been the subject of US Army and USAF trials.

A new mini-RPV (miniature Remotely Piloted Vehicle) of advanced design was delivered to the US Army Electronics Command by Philco-Ford Corporation in May 1974, and is now undergoing flight tests at Fort Huachuca in Southern Arizona. These flights are being made in conjunction with tests of other RPV configurations as a preliminary step in development of the RPAODS programme.

The new Philco-Ford RPV, known as Praeire II is a glass-fibre aircraft measuring only 2.89 m in length, with a 3.66 m wing span, and weighing less than 40 kg. It is a pusher design, with the engine mounted in a streamlined pod above and behind the wing. Its payload is a unique target designation system fitted inside the fuselage nose section. The system employs a TV camera and laser for visual acquisition, tracking, identification and designation of ground targets for precision attack by laser guided projectiles and bombs.

The Praeire II is the newest in a series of mini-RPVs developed by Philco-Ford's Aeronutronic Division at Newport Beach, Calif. The original Praeire I vehicle (from the Latin, "leading soldier") was developed for the Defence Department's Advanced Research Projects Agency (ARPA) under a contract with the US Air Force Aeronautical Systems Division. Like the current Praeire II, the Praeire I system employed a stabilized sighting system with TV and laser for target designation. The Air Force, at Eglin Air Force Base, Fla., conducted a series of highly successful Praeire I RPV flight tests with actual drops of guided weapons against simulated combat targets.

Other versions of this new RPV series include night-time designation systems called "Calere I and II", employing miniaturized FLIR (Forward Looking Infra-Red) sensors in place of the daytime TV sensor.

Primary emphasis by Philco-Ford and the military in the design and development of mini-RPVs has been on extremely lightweight and low cost sensor packages and aircraft systems.

It is expected that the test and engineering phase will continue for at least another year before the stage of placing production contracts is likely to be reached. The Fiscal Year 1975 Defence Budget called for a sum of $5.5-million for continuation of the RPAODS programme.

1821.391
KAMAN RPV AND DRONE PROGRAMMES

DESCRIPTION:

The feasibility of using an unmanned, tethered, rotary-wing, aerial platform for battlefield surveillance and target acquisition will be investigated by Kaman Aerospace Corporation. A Kaman subsidiary, under a $52,000 study contract awarded in early 1974 by the Eustis Directorate, US Army Air Mobility Research and Development Laboratory, Fort Eustis, Virginia.

The study will consider various concepts providing a stable, elevated platform capable of housing sensing devices for search, detection and observation while hovering for lengthy periods at prescribed altitude.

A wide variety of rotary-wing configurations will be analyzed to determine their suitability for use as manned, tethered vehicles, together with their respective ground support requirements. From this analysis, an optimum concept will be selected for further design and study in the context of various mission requirements which may be imposed.

One concept advanced by Kaman envisions a tethered, rotary-wing drone launched and retrieved from a 2½-ton cargo truck. A command and control truck and a fuel truck are included in the system, which has mobility, flexibility and self-sufficiency.

Kaman Aerospace has been active in the design and development of tethered and free-flying, remotely piloted, rotary-wing vehicles for the US Army, Air Force and Navy for more than 20 years. The company currently is under contract to the Navy's Office of Naval Research for development and experimental flight test of a Ship-Tethered Aerial Lifting Platform (STAPL) concept. Two autogyro-type vehicles are being prepared for testing.

Under the contract, Kaman will design, fabricate, flight test and evaluate two unmanned autogyro aircraft equipped with automatic flight control systems and data recording equipment. The self-contained automatic flight control system engineered by Kaman will provide three-axis stabilization and automatic flight path control and contain the necessary redundancy for mission reliability.

Kaman performed concept analysis, feasibility studies and preliminary design planning on STAPL under an initial $78,000 ONR contract several years ago. The tethered system has potential for several applications requiring an elevated platform.

Additionally, Kaman is conducting independent design studies and mission analyses of rotary wing RPVs aimed at the US Army's remotely piloted aerial observation and designation system (RPAODS) real-time target designating requirements (see Entry **1820.391**, above).

Kaman has pioneered in the development of drone helicopters and rotorchutes, producing the world's first remotely-controlled free flying helicopter in 1953 and world's first electrically powered tethered helicopter in 1957. The Kaman QH-43G, a drone version of the HH-43 Huskie helicopter, accumulated several hundred flight hours as a shipboard-based tethered drone, raising a 10,000-foot VLF antenna vertically from a communication ship while underway at sea.

Kaman remotely-piloted drone helicopter under test

Kaman also has designed and developed numerous remote control and automatic control systems for helicopters and other vehicles, including target boats and armoured tanks.

MANUFACTURER:

Kaman Aerospace Corporation, Old Windsor Road, Bloomfield, Connecticut 06002, USA.

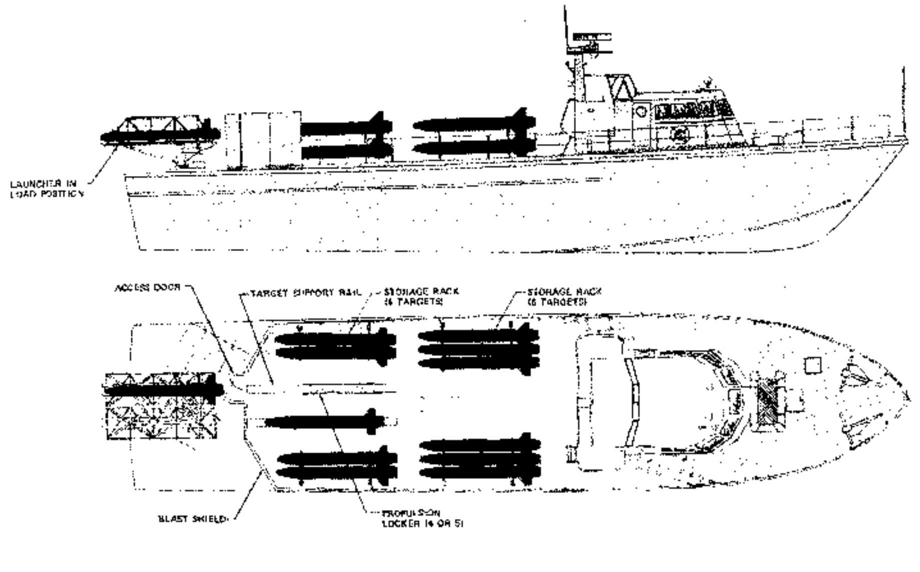
1540.391
SPT-B SELECTABLE PERFORMANCE TARGET-BALLISTIC (BATS)

DESCRIPTION:

Also known as Ballistic Aerial Target Systems (BATS) the SPT-B has been designed as a safe, reliable, and low-cost system principally for troop training with low-altitude air-defence systems. It consists of three major subsystems: Target, Launcher, and Fire Control.

A Naval Ballistic Aerial Target System has been designed to provide low cost, high performance targets for ships at sea and at over water ranges where a sea launch is required.

The system consists of the Improved Ballistic Aerial Target (SPT-B2A), a twin stabilized launcher, and a utility boat mounting the launcher, storage racks and a propulsion storage locker. The target has the same performance and augmenta-



Target Utility Vessel – General Arrangement tion capabilities as the land launched version.

The system is designed to be installed on an 85 ft utility work boat and operated by a crew of 6 men. This configuration has the capability of providing up to 20 targets without resupply. The system can be installed on other customer furnished boats of similar size and construction.

The target airframe is a monocoque structure with an all-metal exterior for radar enhancement and ease of handling. The centre section is a thin rolled metal skin, reinforced with ring frames and polyurethane foam. The nose, aft body and fins are aluminium. Propulsive thrust for the BATS is provided by two to five standard 2.75-inch Low-spin Folding Fin Aircraft Rockets (LSFFAR) for boost and by a sustainer motor using two MXU-4A/A jet engine starter cartridges. The 2.75-inch LSFFAR motors are internally mounted in the aft body and canted so that the thrust vector passes through the target's centre of gravity to provide the minimum safety area requirements. During flight the target is spin stabilized. Spin is induced by the cant of the fins, the cant of the sustainer motor nozzles, and the scarfing of the 2.75-inch LSFFAR nozzles. Three levels of thrust nozzles are available to provide varying flight profiles.

IR, radar, and visual augmentation have been used with the BATS target as well as two types of scoring devices. Visual and IR augmentation may be either nose or tail mounted depending on the weapon and engagement profile used. Radar augmentation is provided by replacing the aluminium nose cone with a plastic cone containing a passive reflector.

Two types of scoring devices are available. An externally mounted miss distance indicator for use with missiles has been successfully used which provides a miss distance in feet. The second, a much less expensive hit indicator, is mounted internally in the nose cone and provides a visual indication of hit by guns or a near hit by a supersonic missile.

Launch control of the targets is provided by the Fire Control Master Unit, the Fire Control Slave Unit, and associated transmission lines and power supplies. The Fire Control Master Unit provides the versatility of selecting any or all of six targets for firing.

The BATS provides the user with a wide selection of flight parameters:

Velocities from 275 to 550 knots, in 75-knot increments

Range to 7,300 metres

Altitude to 6,700 feet (2,042 m)

Flight times to 43 seconds

All parameters are selectable at the launch site with no system modification required. The desired flight performance is achieved by the selection of from two to five booster motors; low, medium, or high thrust sustainer nozzles; and the launch angle.

OPERATION:

A crew of three is required for efficient operation of each BATS launcher installation. Training for total system operation requires less than eight hours. All system components are transportable on a standard US Army 2.5-ton, 6-by-6 truck and are light enough to be man loaded.

STATUS:

Orders to date exceed 24,000 units for delivery to the US Army, US Navy, United Kingdom and Australia.

MANUFACTURER:

Teledyne Brown Engineering, Research Park, Huntsville, Alabama 35807, USA.

2798.391
ROADRUNNER

DESCRIPTION:

Roadrunner is a low-altitude supersonic target drone made by Rockwell International for the US Army. Ramjet-powered and rocket-launched, it is designed to fly at speeds in the region of Mach 1 and at altitudes from 90 to 4,500 metres. It is being used for missile research and development and for training Hawk missile crews.

LEADING CHARACTERISTICS:

Power Plant: Marquardt MA-74 ramjet

Guidance: Radio command. Automatic altitude hold system which can be overriden by ground controller

Launch: From Little John rocket launcher. Boosted by Rocketdyne jettisonable solid-propellant booster rocket

Recovery: Parachute system. Automatic recovery on fuel exhaustion or system failure. Command recovery on ground initiative. Retro-rocket slows missile just before final touchdown

Speed range: Mach 0.9 to 1.4

Altitude range: 90-4,500 metres

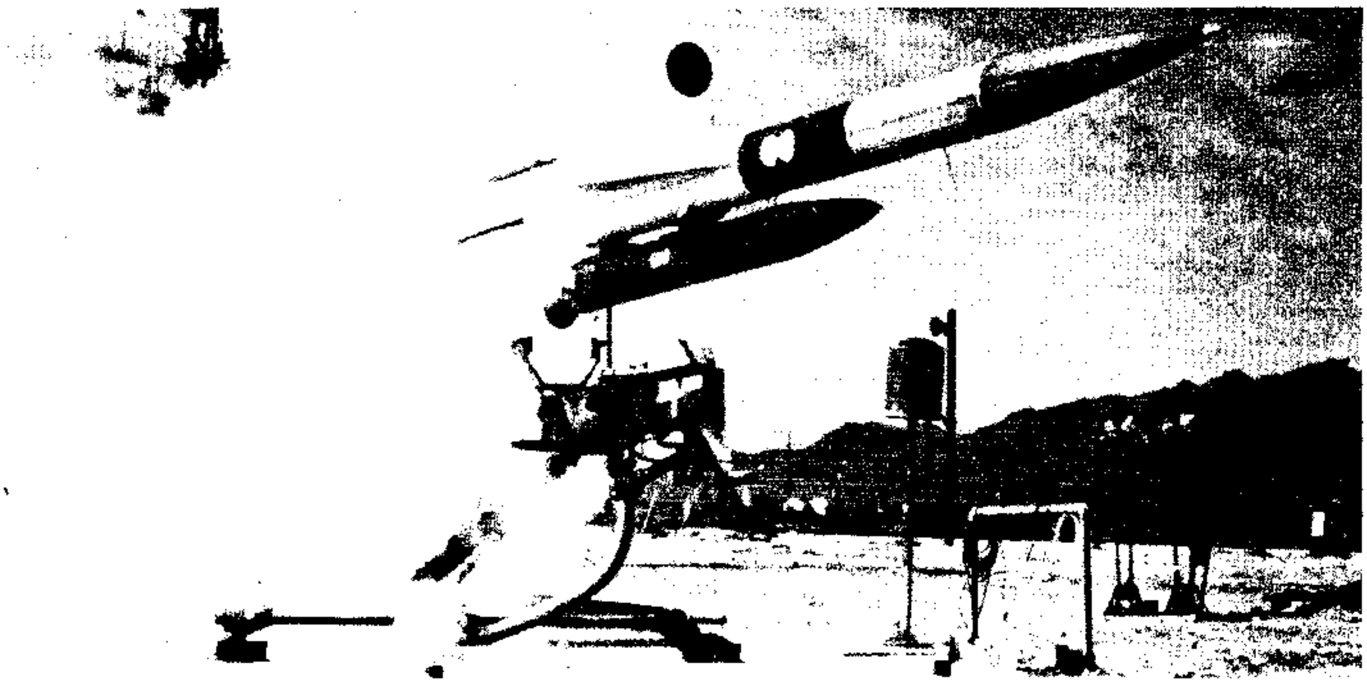
Endurance: 60-90 km

REDHEAD

The Redhead/Roadrunner is a target drone similar to the Roadrunner but has a different Marquardt ramjet, has a speed range from Mach 0.9 to Mach 2.0, an altitude range from 90-18,000 metres and an endurance of some 400 km.

MANUFACTURER:

Rockwell International, Missile Systems Division, Columbus, Ohio, USA.



Redhead/Roadrunner launched at White Sands Missile Range

RECONNAISSANCE SYSTEMS

1504.351
COMPASS RECONNAISSANCE PROGRAMMES

DESCRIPTION:

A number of USAF aerial reconnaissance programmes initiated in response to SE Asia Operational Requirements are known under designations which start with the word 'Compass', e.g. Compass Dawn. The second word is changed to denote differing functions or elements of systems within the overall programme. Although the disengagement of US Forces from Vietnam will have brought many of these programmes to an end, the 'Compass' designation is retained for certain current and planned reconnaissance programmes and projects.

Compass Arrow was a drone reconnaissance programme covering areas of China, and now suspended. Ryan AQM-91A drones were used to carry varying payloads for photo, infra-red and Elint missions.

Compass Bin was a low-altitude photo-reconnaissance drone programme in SE Asia, using AQM-34L drones. The experience gained and some of the hardware and technology are being applied to successor programmes.

Compass Bright is the name of a passive intelligence project which includes the development of an airborne system for automatic direction finding and ranging on a passive basis from both manned and unmanned aircraft. The Compass Cope high altitude drone and the U-2 reconnaissance aircraft are probable vehicles. Funding for Compass Bright is provided under Programme Element 31011F – Cryptologic Activities, and of the several projects under this heading Compass Bright is Project 1148. In January 1974 it was revealed that E-Systems, Inc had been selected to provide the direction finding and ranging system.

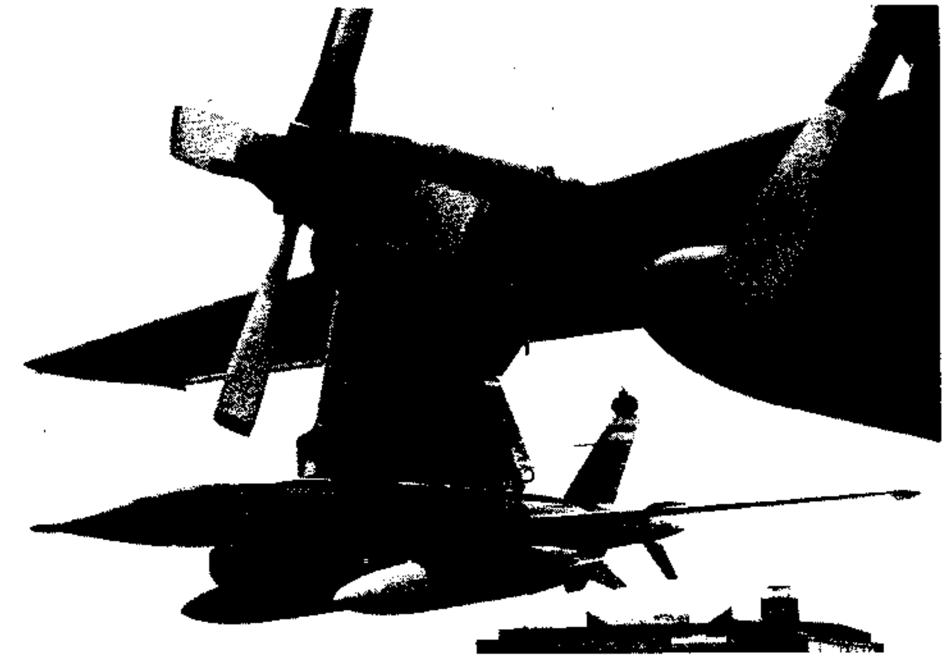
Compass Cope is a programme for the development of high-altitude, long endurance (up to 36 hr), multi-purpose, unmanned, reconnaissance aircraft. These vehicles will accommodate a variety of payloads such as cameras, side-looking radar, time-of-arrival (Elint) receivers, communications relays or Sigint receivers. Unlike current reconnaissance drones, Compass Cope aircraft will be launched and recovered on a runway, instead of air launch and recovery by DC-130 aircraft. Competing designs have been produced by Boeing and Teledyne Ryan.

The initial test flying, preparatory to competitive evaluation, began in Summer 1974. It is funded under Programme Element 64732F which is concerned with reconnaissance and electronic warfare drones and RPVs.

Compass Counter is a USAF project with the objective of pin-pointing a large number of hostile emitters (radar and radio) on a near real-time basis, by means of time-of-arrival techniques. Several aircraft would be used and data would be relayed to ground processors. Seven RB-57 aircraft will be assigned to the test programme, if it is sanctioned.

Compass Dart was developed in 1968-9 for use in Vietnam. HF direction finding techniques were used against specific enemy communications transmissions to determine the positions of targets for air strikes. The major contractor was Sanders Associates.

Compass Dawn superseded Compass Dart although the general principle remains similar. Higher frequencies and coverage of a larger portion of the spectrum were important differences, and the system was intended for the accurate location of enemy radiating sites to provide target designation for a counter air strike. This programme was cancelled, and replaced by TEREC (Tactical Electronic Reconnaissance). This programme, itself, is part of the wider Tactical Information Processing and Interpretation (TIPI) project, funded under Programme Element 64701F, for which $13,400,000 was requested in the FY 1973 budget. There are four functional segments of TIPI.



A Teledyne Ryan Aeronautical Model 147 drone beneath the wing of a launch and recovery DC-130A aircraft. Drones of this category are used for Elint operations of the Compass Dwell programme. Note antennae at fin-top and nose

(1) Image Processing – This is being performed by existing equipment.

(2) Image Interpretation – Development is completed and evaluation started in December 1972, with production following in 1974.

(3) Display and Control / Storage and Retrieval – A four-year prototype development programme was initiated in September, 1971, when Systems Development Corporation was awarded an $11.25 million contract for software, with RCA as major sub-contractor for hardware integration. The Sperry Rand Univac AN/UYK-7 digital computer was selected.

The data storage and retrieval elements of TIPI, constructed and integrated by RCA's Government Communications & Automated Systems Division, were shipped to Langley AFB in July 1974 for Category 2 testing following successful demonstration at RCA's Burlington, Mass, facility. The data segment, called Display and Control / Storage and Retrieval, is housed in 18 integrated shelters, 11 of which will be used by the USAF and seven by the USMC. Hardware development and integration were carried out by RCA under a $12-million contract from SDC.

(4) Tactical Electronic Reconnaissance Processing and Evaluation – A prototype of this segment is to be developed during FY 1973, and TEREC is the sensor element of this segment, and will include sophisticated receivers for the detection and location of radars tracking friendly aircraft. These receivers will be installed in RF-4C aircraft. Litton received a $3-million contract for the TEREC monitoring system in August, 1971.

Compass Dwell designates a programme under which photographic and Elint reconnaissance missions of long duration are performed by Teledyne Ryan 147 drones flying at high altitude. A major objective is the accurate location of hostile radar sites.

Compass Ghost was the name assigned to a programme originated in 1971-72 to investigate and develop electro-optical counter-measures systems and equipment for USAF tactical aircraft. Contractors involved were Systems Research, Electro-Optical Systems, and Holobeam.

Compass Home is the designation given to another method of locating hostile ground radars. Development was undertaken by Westinghouse, and the technique entails the use of an F-4 aircraft's A1 radar which is locked onto the transmissions from the ground radar.

Compass Link is the code name allocated to a secure data link for the relaying of reconnaissance information from Vietnam to Washington via the Initial Defence Communications Satellite System. Because of the distance between the terminals, data was sent in two 'hops', with a relay facility at Hawaii where there were also facilities for readout of the information.

Film returned from a reconnaissance flight is scanned by a laser system and the analogue signals are converted into digital format before encrypting. The encrypted form is used for multiple frequency shift keying of the RF carrier.

The system was developed by Philco-Ford under a $4.6 million USAF contract, and went into operation in December 1968.

Compass Matrix, although associated with reconnaissance programmes, is essentially an Electronic Warfare project. It entails the development of a sophisticated and comprehensive system of management for aircraft ECM equipment in response to the nature of the threats detected and encountered. In March 1974 the USAF Avionics Laboratory selected companies to undertake studies of methods of making more efficient use of available jamming energy, while conducting with Westinghouse studies of power management techniques for the ALQ-119 jamming pods carried by F-4 fighter-bomber aircraft. In June 1974 it was announced that a fly-off evaluation of competitive power management concepts proposed by Loral and Itek was being planned by the USAF.

Compass Quick is also connected with electronic warfare and is the code-name of an updating programme for the Elint systems and equipment of EC-135 aircraft.

Compass Robin is a little-known sensor system for the collection of Elint on certain threat systems, and employs a so-called "implant" type of sensor. The USAF sponsored a $1.5-million development effort during FY 1973.

Compass Sight is a system by means of which infra-red reconnaissance information gathered by RF-4C aircraft is sent via data link to a ground station. The video data link is produced by the Cubic Corporation and probably operates at C-band frequencies. The system also has provision for relaying data via a second, higher aircraft as an alternative to direct air-to-ground transmission. The system was developed in response to SE Asia Operational Requirement 45, and three RF-4Cs are believed to have been equipped with sensors, and two B-57Es with relay equipment.

Compass Strike is a system of locating radars from two or more aircraft by means of time-of-arrival techniques. The broad principle employed is that two aircraft, a precisely defined distance apart, measure the difference in respective times of arrival at each of a pulse from the radar to be located. Lines of constant time difference are parabolas, and the initial measurement will locate the emitter on one of these. A second measurement taken after the other will produce another parabola, which, where it cuts the first one, defines the position of the emitter in two co-ordinates.

While simple in principle, this technique clearly calls for considerable equipment sophistication, when it is considered that the measuring platforms are moving at high speed and need to know their relative and absolute positions with considerable accuracy. Other problems are the provision of synchronisation facilities to provide an accurate timing reference and a means of ensuring that the same transmitter signal is timed. This is further complicated by the high data rate presented by the target radar and what this means in terms of ambiguity. To resolve these problems calls for powerful data processing and computational facilities, and digital processors are employed.

The original Compass Strike project began as QRC-334 and was fitted to F-4 aircraft. These had to fly close to each other because of the need to resolve the ambiguity problem just mentioned. The later programme, QRC-385, incorporated techniques evolved by IBM which removed this requirement and the use of larger aircraft, such as the EC-135, at greater separations is a possibility.

1397.151
IGLOO WHITE SURVEILLANCE SYSTEM

DESCRIPTION:

Igloo White is the code name given to an ingenious concept for the remote detection of transport vehicles and other military traffic from the air with the objective of initiating and directing air strikes against such traffic. It was employed by American forces in South Vietnam and the results obtained have led to similar systems being contemplated for other theatres, such as Western Europe. For this reason the following description of the SE Asian system is retained although it is now almost certainly completely dismantled.

The three principal elements of the system are: (1) air-dropped sensors, (2) a loitering aircraft that monitors the outputs of these sensors, and (3) an Infiltration Surveillance Centre (ISC) to which data is relayed by the aircraft. The information thus obtained is used to direct strike aircraft, either immediately against the moving traffic flow, or later at an area containing a computed concentration of vehicles.

Four types of sensor are employed, two based on acoustic principles and two relying upon seismic effects. The first two are based on sonobuoy technology, but with modifications appropriate to use on land, in particular the replacement of the underwater sonar transducers by microphones. One type, the Spikebuoy, is dropped from the aircraft, and aided by a pointed nose, penetrates the ground to the extent that only the radio antenna is left above the surface. The other acoustic sensor is the Acoubuoy, which is parachuted from the aircraft and is designed to suspend itself amongst the foliage of trees.

The most widely employed sensor is the ADSID (Air Delivered Seismic Detection Sensor), which is deployed in a similar fashion to the Spikebuoy but incorporates a seismic detector in place of the microphone. This sensor is stated to be capable of presetting to activate the associated radio transmitter only when vibrations of specific amplitudes and characteristics have been detected.

The fourth type of sensor, Acousid, combines seismic detection with a microphone which can be remotely activated to provide either confirmatory acoustic information, or additional data that can be provided by a microphone after initial detection by seismic means.

A further type of sensor, which has not been identified positively with Igloo White but which is likely to be associated with it is EDET. This is an air-dropped remote sensor for the detection of internal combustion engine ignition systems. It was added to the US inventory in Fiscal Year 1971.

The emplacement of sensors is planned in accordance with other intelligence information such as aerial photographs, observation flights, battle reports, etc.

The relay aircraft employed originally was a version of the Lockheed EC-121R. This aircraft, a military variant of the four-engined Constellation, is large and relatively costly to operate, and it was later joined in this role by other types.

One of these was a special version of the Beech Debonaire, a single-engined commercial aircraft, and another was the Beech Bonanza, these being equipped under the programme code-named Pave Eagle. The smaller capacity of these machines limited their use to that of a relay platform only, whereas the EC-121R can carry the crew and equipment necessary to permit analysis of sensor data and possibly the direction of air strikes. The Beech Bonanza aircraft were converted for a form of drone operation, though in fact carrying crew, and were designated QU-22B aircraft. In operation they had an unfortunate safety record which led to changes in their use.

The Infiltration Surveillance Centre is equipped with communications and control systems for the collection of relayed sensor data and the direction of relay aircraft and strike forces. It also has extensive computer and data processing facilities for the analysis, display, and interpretation of results. In support of this complex, a Deployable Automatic Relay Terminal (DART) facility has been developed. This is air transportable, but is less sophisticated than the ISC proper, and relies upon human interpretation of data as it is received.

A more sophisticated version of this, with computer facilities and capable of integration with the Tactical Air Control System was under development in mid-1971.

DEVELOPMENT:

Development was directed by the US Defence Communications Planning Group, and the concept originated within the Institute of Defence Analysis. The system became operational in Vietnam in December 1967. Total cost of Igloo White to mid-1971 was $725 million.

STATUS:

Following the US withdrawal from Vietnam, Igloo White is assumed to have been dismantled, but plans to evolve a similar system or systems for possible deployment in Europe have been initiated. This is known as REMBASS (Remotely Monitored Battlefield Sensor System) and is based on use of sensors used in SE Asia, modified for use in Europe. In advanced development by early 1974, REMBASS may enter full-scale development in 1975, depending upon a decision by the end of 1974. A sum of about $10.6 million would be required.

1899.351
PAVE STRIKE PROGRAMMES

DESCRIPTION:

Pave Strike consists of eleven distinct projects which have been selected for special and co-ordinated treatment to improve the USAF tactical all-weather strike, defence suppression and night attack capabilities. Each of the eleven systems is part of the composite group of capabilities needed for effective night and all-weather strike capability. The Fiscal Year 1975 plan envisaged a total expenditure of $40-million on the eleven programs, which are (with their Programme Element and Project Numbers, where known):

(1) Modular Guided Glide Bomb II (PE 63741F, Project 1901)
(2) EO Glide Bomb – EOGB II (PE 64733, Project 2076)
(3) DME Guided SUU-54 Dispenser, Pave Storm Cluster Bomb (Project 5974)
(4) Precision Emitter Location and Strike System – PELSS (PE 64742F)
(5) Deployable Data Base (Project 2106)
(6) Airborne Locator and Strike System – ALSS (Project 1949)
(7) EF-111A Manned Support Jammer Aircraft (PE 64220F)
(8) Advanced Development of Imaging Infra-Red Guidance (PE 64709F Project 2144)
(9) Laser-guided Maverick (PE 64608F)
(10) Pave Tack Pod (FLIR and laser target designator pod for F-4 and F-111) (PE 64709E Project 2056)
(11) Multi-mission RPV (PE 64732F Project 2107)

Five of the eleven projects are concerned with target detection and acquisition, items (4), (5), (6), (10) and (11) above.

The Deployable Data Base is a photogrammetric target data base which incorporates a facility for putting DME co-ordinates onto photographs to provide precision target location information. On this data base, with computer processed information, it will be possible to overlay a variety of reference grids and to rapidly convert co-ordinates from one reference frame to another to suit the strike system to be employed.

The airborne Locator and Strike System (ALSS – also officially translated in US Government publications as Advanced Location and Strike System) has been under test since October 1972 and has involved the use of DME guidance for a variety of air-to-surface munitions. Although limited in frequency and capacity, ALSS has located emitters (eg radars) at ranges of 150 miles. Employing DME guidance, weapons have been delivered to simulated enemy emitters at stand-off ranges.

The more advanced PELSS will provide a capability for precision location of emitters by Time-Of-Arrival and Distance Measuring (TOA/DME) techniques. Compared with ALSS, this system will have enhanced capabilities for the location of targets (probably in the face of ECM or ECCM) and for the direction of a wider range of munitions.

The Pave Tack pod is a combined Forward Looking Infra Red (FLIR)/laser ranging/target designator pod to provide a night search and track capability for laser-guided, Imaging I/R-guided, and free-fall weapons delivery.

The Multi-Mission RPV programme provides for the modification of the BGM-34C drone, by modularising the nose section to allow for either a Reconnaissance Module or an Electronic Warfare Module to be carried, in conjunction with a variety of wing and fuselage store stations for the deployment of air-to-surface weapons appropriate to the category of target to be attacked.

1898.351
US NAVY OCEAN SURVEILLANCE PROGRAMME

General:

US Navy programme directed toward effective global ocean surveillance embraces four main lines of research and development:

(1) EPX, which is a very high altitude surveillance and reconnaissance aircraft
(2) An ocean surveillance satellite system, using available technology
(3) An advanced satellite sensor system
(4) A geostationary satellite system to relay reconnaissance and surveillance data to ships of the Fleet directly.

In these programmes there is co-operation with the USAF, but the precise extent of this collaboration is not known. Most of the USN activity in the area of ocean surveillance is funded under one or other of the following Programme Elements, for which the Fiscal Years 1974 and 1975 allocations are indicated ($ millions, FY 1975 figures in brackets):

63516 N	Radar surveillance equipt	2.5	(7.3)
63522 N	Advanced sub surveillance equipt	4.7	(4.9)
63763 N	Aerospace ocean surveillance	25.8	(24.1)
63717 N	Integrated ocean surveillance information	5.7	(4.5)
64508 N	Radar surveillance equipt	8.3	(10.9)
64515 N	Sub surveillance equipt	8.4	(9.4)

Related Programme Elements which may provide funding for some part or associated facility for ocean surveillance are:

63519 N	Advanced command data system	3.9	(5.1)
28010 N	Joint tactical communications	1.8	(15.2)
33109 N	Satellite communications	41.5	(27.3)
33401 N	Communication security	3.3	(4.3)
63520 N	Advanced communications	2.6	(2.2)
35111 N	Project W37X3: Satellite Data Processing System.		

In the context of the total USN space programme, the surveillance aspects have been officially outlined as follows:

The Navy Space Programme will provide better and more rapid ways of gathering information over broad areas of the Earth by satellite; the information will be correlated and evaluated, then transmitted via satellite to the commander at sea for consideration in his decision-taking process. Orders to subordinates arising from this will be transmitted to them by satellite. The objective is to provide near real-time surface ocean surveillance to task force commanders world-wide. Neither local assets (aircraft) nor wide coverage assets (satellites) can meet all requirements all the time in a cost-effective manner. Space sensors which provide broad area coverage at reasonable re-visit intervals are appropriate in times of increasing tension. Airborne sensors providing greater accuracy and more frequent contact are needed closer to a task force during heightened tension or actual conflict. A concept of complementary air and space-borne sensors to accomplish this is in advanced development. The space segment, formerly Programme 749 has been combined with very high altitude aircraft sensor experiments under the new and comprehensive Aerospace Ocean Surveillance programme element (63763 N).

The programme will provide the necessary air and space sensors which will be integrated with data processing and display systems to present required data in near real-time. These systems will also be interfaced with the National Command Authority to provide information as desired. Information derived from the space and airborne sensors will be combined with complementary data on an all-source basis available from the automated intelligence data base. This will remove most of the burden of analysis from field commanders and provide filtered information to permit rapid combat or action decisions.

As part of the programme of sensor evaluation, the USN for a period of about two or three years has been obtaining USAF reconnaissance satellite data. It has been suggested that the USAF data is used for comparison with and evaluation of data obtained from experimental USN satellites which are thought to include a variety of thermal imaging and infra-red sensor packages. Radar is another form of sensor which is known to be under examination for the ocean surveillance satellite.

The airborne sensor development part of the programme began in 1974 with a $3.4 million contract for the modification of a high-altitude U-2 aircraft by Lockheed, into an advanced version of the EPX surveillance aircraft. This followed successful flights of an experimental ocean surveillance aircraft (based on a U-2 loaned by the USAF) during 1973.

The new EPX aircraft is planned to begin trials off the Southern California coast early in 1975. Among the sensors selected is a dual electro-optical surveillance system comprising an infra-red imaging sensor and a low-light-level television camera, which is being developed by Xerox. These sensors will be mounted on a common stabilised platform contained in a 20-inch (51 cm) diameter sphere in the nose of the U-2. The EPX will also carry an Elint receiver (which had not been selected at the time of going to print) and an ASV radar, which will probably be the APS-116 which is standard on the USN P-3C Orion maritime aircraft. The earlier test vehicle employed a modified RCA commercial weather radar for this function.

In July 1974 it was reported that conflicts of schedules were creating difficulties for the Navy in maintaining the pace of flight programmes connected with the EPX project and it was suggested that the options available were changing to an alternative type of aircraft (if a suitable type could be found) or re-starting the U-2 production line.

Although no details apart from those given above have been obtained, some indication of the scope is given by the titles of specific projects contained within the Programme Elements listed above. Some of these are given below:

33401 N	Communication Security:	
	Project X3291	Clarinet Vallor
	Project X3299	Clarinet Plato
63763 N	Aerospace Ocean Surveillance:	
	Project W3518	Aircraft Systems
	Project W3519	Space Systems
	Project W3520	Advanced space systems
	Project W3521	Space systems applications

1624.351
AMERICAN SATELLITE PROGRAMME

General:

American military satellite launches identified for the year 1973, as summarised in the adjacent table, show an impressive consistency in comparison with the programme for 1972, which year was notable for the contrast in numbers of satellites required to fulfil the US requirement compared with the much higher numbers needed in earlier years. This feature of the American satellite programme and the historical background to the various development projects were discussed at some length in Jane's Weapon Systems 1973-74. The following paragraphs are intended to summarise the present position and outline future developments.

The USAF is concerned with four satellite programmes for current operational requirements, these being concerned with communications, missile launch early warning, reconnaissance, and meteorological data collection. A fifth area which involves collaboration between the USN and USAF is that of satellite navigation systems.

Meteorological Satellites:

The Defence Meteorological Satellite Programme is managed and operated by the USAF. Two satellites are required on-orbit to continuously collect visual and infra-red data on weather conditions around the world. The data is processed by the Air Force Global Weather Central for distribution to both military and civil users. Two generations of Satellite are current, those of later design having a longer orbital life than their predecessors.

Built by the Lockheed Missiles and Space Company for the USAF, the Agena space vehicle has been the carrier of numerous classified Earth orbiting missions

Infra-Red Missile Warning Satellites:

The infra-red early warning satellite series is a principal component of the US deterrent complex. Appropriately sited geostationary satellites ensure that no long-range missile can be launched from any part of the Earth without the event being signalled to the US military authorities. The system also provides an element of impact prediction.

Reconnaissance Satellites:

Short duration photo-reconnaissance satellites have virtually disappeared from the American launch tabulations, having been replaced by the Big Bird series which have typical durations of two or four months, and others which are assumed to be for reconnaissance purposes and which have a life of four or five weeks. Either or both types may include an Elint capability.

Communications Satellites:

The DOD has two basic and independent types of satellite communication system included as elements of WWMCCS (World-Wide Military Command and Control System). One type provides long-distance, point-to-point, high data rate traffic using large ground and shipboard terminals. This system, in general, carries 'strategic' command global traffic, as well as intelligence data, high priority warning, and special communications. The second type provides the essential command and control communications needed for the employment of forces to carry out the Single Integrated Operating Plan (SIOP). Because of the requirement to support many mobile users equipped with smaller terminals, such as aircraft and dispersed naval units, this type of communication system provides low data rate traffic at a very low bit-error rate. The Defence Satellite Communication System (DSCS) provides the first type of service. The Air Force Satellite Communication (AFSATCOM) system and the Navy Fleet Satellite Communication (FLTSATCOM) System provide the second type. The DSCS is managed by and is under the operational control of the Defence Communications Agency, and the USAF is responsible for acquisition and orbital servicing of the space element of DSCS. The system consists of four satellites which between them provide a global capability. The planned orbital life of these satellites is three years.

The AFSATCOM system is managed and operated by the USAF and consists of: the Satellite Data System (SDS); the Air Force portion of FLTSATCOM; and the user terminal equipment and backup transponders which are placed in orbit as pickaback payloads on other host satellites orbited by the DOD.

The FLTSATCOM is managed and funded by the US Navy, but the USAF is responsible for procurement of the spacecraft.

The original procurement of DSCS satellites was for six Phase II models, and the first two were launched in November 1971. These developed trouble in orbit and eventually failed. The remaining four satellites were modified to correct all the deficiencies detected in the first two, and the second two spacecraft were launched in December 1973. Results were reported as satisfactory and the remaining two are planned to be sent up in the first half of 1975.

NAVIGATION SATELLITES:

For several years past both the USN and USAF have been studying alternative satellite navigation systems to meet future multiple user requirements, and for a longer period the USN has maintained an operational system variously known as Transit or Navsat. Although the desirability of combining the USN and USAF efforts into a single system has long been acknowledged, this objective has not been easy to attain. But a fresh programme has been presented for approval, which offers reduced cost and a solution which is apparently compatible with both USAF and USN needs.

The new programme is designated the Global Positioning System, but has already attracted the alternative popular name of Navstar. It is intended to enable various types of user, such as ships, aircraft, land vehicles, or soldiers, to obtain high-accuracy, three-dimensional fixes, reportedly within about 10 metres. Velocity measurements would also be possible.

A night picture of the Eastern States of the USA, the Great Lakes and part of Canada taken by moonlight from the USAF Defence Meteorological Satellite. The sensors and ground processing equipment which produced this picture were developed by Westinghouse Systems Development Division

The DoD has given approval for the first phase of the programme which will run until 1978 at an estimated cost of $150-million. This includes design and development of user equipment, the production of a cluster of satellites, their launch, and extensive test and evaluation programmes.

US MILITARY SATELLITE LAUNCHES IN 1973

Designation	Launch Date	Launcher	Inclination (deg)	Perigee/ Apogee (km)	
1973-13	6.3.73	Titan IIIC	0	33533/35901	Integrated Missile Early Warning Satellite
1973-14	9.3.73	Titan IIID	96	152/270	Big Bird reconnaissance satellite 71-day duration
1973-28	16.5.73	Titan IIIB – Agena D	110	135/352	Photo-reconnaissance 5-week duration
1973-40	12.6.73	Titan IIIC	0	35570/35890	Integrated Missile Early Warning Satellite
1973-46	13.7.73	Titan IIID	96	156/269	Big Bird reconnaissance satellite 91-day duration
1973-54	17.8.73	Thor-Burner II	99	813/851	USAF meteorological satellite
1973-56	21.8.73	Titan IIIB – Agena D	63	460/39330	
1973-68	27.9.73	Titan IIIB – Agena D	110	131/385	Reconnaissance satellite 32-day duration
1973-81	30.10.73	Scout	90	893/1150	US Navy navigation satellite
1973-88	10.11.73	Titan IIID	97 96	146/275 486/509	Reconnaissance satellite 4-month duration Unidentified pickaback payload
1973-100	14.12.73	Titan IIIC	2	35340/36290	Defence Communications Satellite(s)

1625.351
COSMOS SERIES SOVIET SATELLITES
GENERAL:

Soviet Cosmos satellite launches in 1973 were appreciably more numerous than in 1972: 85 as compared with 72 in the preceding year. Of this total no less than 35 were of the now familiar (ie in terms of orbital characteristics) reconnaissance series with a general orbital duration of about 15 days. The comparable number of launches for this category in 1972 was 29, and the general pattern of distribution between the various orbital inclinations employed is very similar for both years. The one exception is the significantly increased use of the 73 degree slot in 1973 when launches were more than twice as numerous as in the preceding year – thirteen compared with five. Although there is little doubt that the Middle East conflict of 1973 accounted for some of the increased Soviet reconnaissance satellite activity (in October there were launches on the 3rd, 6th, 10th, 15th, 16th, 20th and 27th) this period accounts for only half the additional 73 degree satellites.

No official information whatsoever is published by the Soviet authorities concerning military satellite activities and the information that can be assembled is the result of analysis of the satellite orbital data tabulations published by various official and semi-official bodies in the West. A comprehensive review of this information, and of the surveys carried out by a number of authoritative observers, was published in the last edition of Jane's Weapon Systems, and readers are referred to this and preceding editions for the historical and statistical record of the complete Cosmos programme.

LAND BASED AIR DEFENCE SYSTEMS

2177.181
INTRODUCTION

In this section are described some of the surveillance and control systems that are either installed or being developed or on offer for installation in several countries. Not all existing or proposed air defence systems are described; partly because information on some is not available and partly because others consist of standard equipment, purchased from major supplier countries, which is already described elsewhere in this book. Because of this some well-known systems have been omitted and some systems that are known or believed to be impending are at so early a stage that virtually nothing useful can be said about them.

Inevitably the section covers systems of a wide range of sizes and complexities but the main purpose of all is the same – the acquisition of information concerning potentially hostile aircraft, missiles or other objects in space and the organisation of that information in a way that will enable positive action to be taken if necessary.

AUSTRALIA

2016.181
HUB CAP

DESCRIPTION:

Hub Cap is a sophisticated mobile control and reporting unit (CRU) for air defence designed by Plessey and based on a specification written in close collaboration with a team of Royal Australian Air Force officers. It is currently deployed in Australia.

The system provides three-dimensional airspace surveillance and control of supersonic fighters to intercept hostile targets over a wide area from fully mobile air conditioned shelters designed for deployment by C-130 aircraft.

The use of digital computing permits automatic tracking of targets from the primary radar while plot extraction from the secondary radar returns is used to reinforce the primary radar auto-tracking. For the RAAF requirements, the computer is programmed to take account of the Mirage III characteristics, performs an assessment of an interception situation when supplied with the relevant data on weapon availability, and provides a number of alternative intercept solutions for selection by a controller. The computer can be reprogrammed to enable the system to operate equally effectively with other types of fighter. Comprehensive communication facilities are provided with Hub Cap enabling operational personnel to communicate with each other, with aircraft under control, and with units external to the system.

SYSTEM ELEMENTS:

Major elements of the system are:-

1. A Westinghouse TPS-43 (**2517.153**) 3-D primary radar with comprehensive anti-jamming and clutter rejection facilities.
2. IFF secondary radar.
3. A digital computer system, with redundancy, using two Marconi "Myriad" digital data processors, together with Plessey digital interface equipment, bulk data storage and programming.
4. An operations room complex using Plessey TDS Mk V data handling equipment with labelled plan and tabular displays.
5. UHF, VHF, HF and telephone communications equipment controlled by Plessey "Minicom" communications control equipment.
6. Diesel primary power generators.
7. Microwave link for data transmission between radar and operations sites.

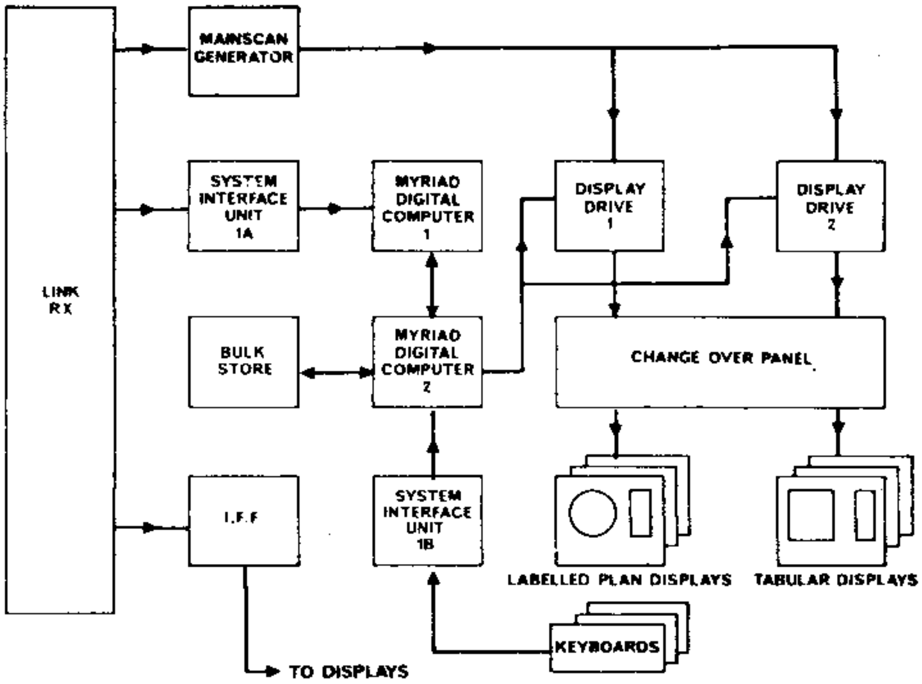
SYSTEM FACILITIES:

The operational organisation, upon which the capabilities of the system depend, has in overall command the air battle commander. Under him the organisation divides into two groups:-

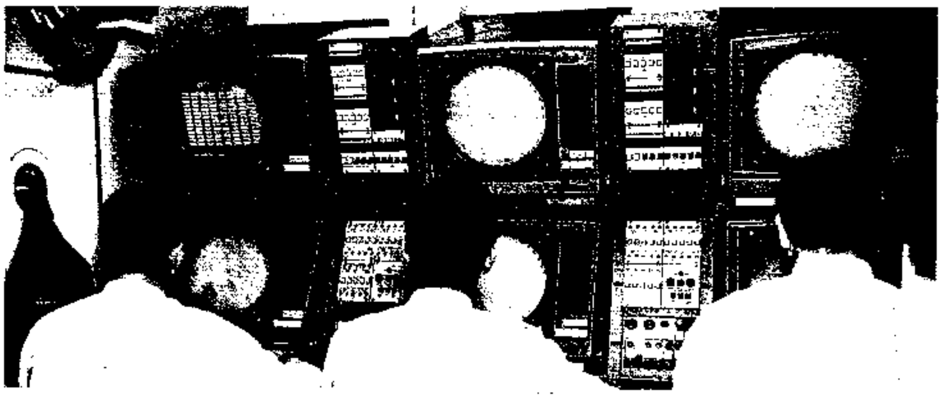
The tracking group: comprising a tracking supervisor and identification and tracking operators.

The weapon control group: comprising a weapons assignment officer in charge of fighter controllers, surface-to-air missile and anti-aircraft fire controllers.

With the exception of the trackers and the weapon assignment operators who require only labelled plan displays and tabular displays respectively, all other positions in the display complex are provided with identical consoles each comprising:



Schematic of the Hub Cap display and data processing equipment



Hub Cap displays

Plessey TDS Mk V labelled plan display
Plessey TDS Mk V tabular display
Rolling ball symbol position control
Tabular keyboard for symbol selection
Tabular keyboard (general purpose) for insertion of alpha-numeric data to computer, and for call-down of data from the computer.
Plessey 'Minicom communications control.

Thus flexibility in operating positions is maintained, allowing for changes in operational philosophy and graceful degradation in the event of equipment failure. The provision of data input and output facilities and communications facilities at each operational position, together with solutions to each concurrent interception computed at every phase of the fighter's profile, permits instant assessment of a tactical situation. This provides accurate figher control of each interception with minimum delay.

The system is capable of controlling engagements by surface-to-air missiles and air-to-air weapons to the point of firing.

Under normal conditions each tracker will handle several targets simultaneously using the automatic tracking facilities of the computer, his task being to monitor the performance of the automatic tracking with reference to targets allocated to him. However, the facility is retained for a tracker, under adverse conditions, to revert to manual initiation and rate-aided manual tracking in which his task is to initiate tracks and to correct these tracks as target manoeuvres occur.

MOBILITY:

All Hub Cap equipment, with the exception of the radar and the primary power generators, is housed in fully air-conditioned cabins with running gear suitable for second-class roads. The cabins all have a standard width, being suitable for storage aboard C-130 aircraft, and are tailored in length to accept their requisite equipment with a minimum of redundant space, yet retaining excellent access to the equipment for maintenance purposes. Two cabins containing communications, data link and workshop, are located at the radar site.

Five cabins containing communications, tracking control, data processing, command and workshop are located at the operations site.

The workshops need not form an integral part of the system and may be deployed separately depending on transport priorities.

The primary radar is housed, complete with the necessary transmitters, receivers and IFF equipment in an inflatable radome; while the primary power supplies are free-standing in the open with their own covers.

DEVELOPMENT HISTORY:

As already noted this system had its origins in a RAAF requirement and the first design study was carried out in 1965. The equipment went into service with the RAAF in 1969. No other immediate customers are known for Hub Cap as such, but the basic system principle is capable of being realised in a variety of different ways.

MANUFACTURERS:

Prime contractor: Plessey Radar Ltd., Addlestone, Surrey.

BRAZIL

2166.181
DACTA ATC AND AIR DEFENCE SYSTEM

DESCRIPTION:

In October 1972 a $70 million contract was concluded between the Brazilian Ministry of Aeronautics and Thomson-CSF, France. The agreement related to the construction of an air traffic control/air defence radar system in Brazil.

Details of the agreement are not known; but it is understood that a substantial element of licensed manufacture in Brazil was included – thus committing the French company to building up a substantial electronics manufacturing industry in the customer country.

Another agreement signed in 1972 involved the French and German joint developers of the Roland I missile system (**2218.131**) with the Brazilian Army's Central Missile Commission. Here again manufacture under licence was involved: in this instance, however, it is understood that the licence related to final assembly only.

It is evident that the Brazilian authorities are intent on strengthening the country's capabilities in the manufacture of arms and other defence equipment. Brazilian capabilities in the naval and aviation fields are well-known as also are some of their activities in the development of weapons for their land forces. Developments in electronics have been less prominent, but in addition to those mentioned above it is understood that there will shortly be an announcement of a joint-venture programme of computer manufacture.

CHILE

2167.181
AIR DEFENCE SYSTEM – CHILE

DESCRIPTION:

Late news as we go to press is that the Chilean Government is considering the desirability of setting up an air defence system incorporating radars that can survey the air space above and adjacent to the country's northern territory. Chile's right to this territory has been disputed ever since it was taken from Peru a century ago; and the Chilean authorities are worried by the increasing strength, in aircraft and weapons, of the Peruvian armed forces.

It appears that, if the authorities decide to proceed with the project, the system would probably be formed by integrating five existing civil ATC radar stations, believed to be equipped with Texas Instruments surveillance radars under a single co-ordinated command and control system.

STATUS:

Government consideration

CHINA (PEOPLE'S REPUBLIC)

2052.181
CHINESE AIR DEFENCES

No detailed information on Chinese air defences is available, but there are some known statistics on their magnitude.

Until comparatively recently the Chinese were reported to have in service about fifty surface-to-air missile sites and some 4,500 anti-aircraft guns of various types. Associated with all of these were about 1,500 air defence radars, but to what extent and in what way these are organised in air defence systems was not known. More recent information, while still leaving much open to question, suggests that the country's defences are being substantially modernised: new radars, it seems, have been designed and improved versions of the SA-2 Guideline missiles (**2942.131**) which the Chinese originally acquired from the Russians are being produced.

It should also be noted that at least one very large phased-array radar aerial has been constructed in Western China, presumably as part of a missile warning system. No details are available.

FRANCE

2106.151
MIDAS AIR DEFENCE SYSTEM

DESCRIPTION:

This code-name is used by the manufacturers for a mobile air-defence centre which can be associated with Matador (**2012.153**) or a similar radar.

The MIDAS operations centre comprises a single cabin, transportable by road, rail or cargo aircraft, in which are assembled the display processing equipment, the computer and its peripherals, telecommunications equipment, and four operator positions.

Three of these positions have display consoles, each equipped with:

a PPI display for the presentation of raw video, synthetic video, tracks, electronic map, vectors (aid to navigation), etc.,

two microtabular displays for the presentation of interception data provided by the computer and the operator,

a designation device (rolling-ball unit),

an order keyboard,

a radio control panel.

The fourth position is for a telecommunications operator who assigns radio devices to the other operators and manages a teleprinter. This position includes a telephone exchange.

OPERATION:

The three consoles, which may have any assignment, are in principle distributed as follows:

1 master controller position,
1 tracking controller position,
1 interception controller position,

The master controller supervises the whole station and is particularly in charge of identification, of the threat evaluation, of the decision to initiate an interception, and of the choice of weapons. In case of need he can also control a maximum of two interceptions.

The tracking controller is in charge of establishing the general air situation. In particular, he has to initiate manually designated tracks, which then are followed automatically by the computer; he assists the computer when tracks cross or run into clutter or interference. He can also assist the master controller in his task of identification (especially when the master controller has to control interceptions).

The interception controller can control two simultaneous interceptions.

The system can also be supplied in a five-console configuration thus –

1 chief controller position
2 tracker positions
2 intercept controller positions

CAPACITY:

Automatic following of 20 tracks,
4 simultaneous interceptions,
Remoting of tracks (2400 bauds),
Remoting of 200 primary or secondary plots (2400 bauds).

TRAINING:

The computer incorporates a simulation programme capable of creating a synthetic air situation which can be superimposed on the real situation to permit the training of operators with real aircraft.

STATUS:

The system is in production

MANUFACTURERS:

Thomson-CSF, Division Radars de Surface, 1, rue des Mathurins, 92222 Bagneux (France)

Thomson Visualisation Traitement, 40, rue de la Grange Dame Rose 92360 Meudon (France)

2115.151
MINISTRIDA AIR DEFENCE SYSTEM

DESCRIPTION:

MINISTRIDA is the name given by the manufacturers to a dual-purpose computerised air defence/ATC system of medium capacity conceptually derived from the French national air defence system STRIDA.

Inputs to the system can be taken from a variety of primary radars provided height is included in the input data. Typically suitable radars, bearing in mind the mobility of the system, are Matador (**2102.153**), TPS-32 (**2516.153**) or TPS-43 (**2517.153**) 3-D radars or any of a number of 2-D radars in conjunction with a mobile nodding height-finder – the latter combination being appropriate when the main object is the automation of an existing system. IFF/SSR inputs are also required: these can come from either independent or on-mounted sources.

A vital feature of the system is the elaborate computer programme which consists of a common trunk and two branches. The common trunk has a bias towards military requirements but the branches are specifically military and civil in their objectives. Information processed by the two branches can be either separately displayed or brought together on a common display or displays. This flexibility could, of course, be useful if circumstances required an increased concentration of effort on military rather than civil operations.

The system can be built as a mobile station or installed in a fixed ground centre. It can be installed as original equipment in Air Defence or Air Traffic Control Systems or introduced later for improving the capabilities of an existing system.

MOBILE STATION:

The main functions of a mobile station are to present the air situation, to evaluate threats, select targets and weapons, taking account of resources, and to guide interceptors and provide for their recovery. The station can also alert threatened centres, provide close control and navigation aid for aircraft in operational flight, detect conflicts (anti-collision) and train controllers in interceptor guidance.

The basic version of the station provides for automatic processing of 50 tracks and 4 simultaneous intercept/recoveries. It comprises 8 air-ground voice transmission links (8 VHF or UHF transceivers). This mobile station can also be used for ATC functions with appropriate programmes.

The basic version of the station consists of 2 air-conditioned cabins; one cabin housing 4 operational positions, each of which provides display (labelled situation display and alpha-numeric screen) dialogue and communications facilities (radio communications, intercommunications and telephone links). The display equipment presents superimposed the raw radar video and the synthetic picture. An extended version of the system can incorporate 5 operational positions.

The second auxiliary or technical cabin contains data processing equipment (extractor, processing system) and radio transmitters. The cabin also contains positions for auxiliary functions e.g. technical testing, piloted aircraft simulation and data gathering.

The station also contains:

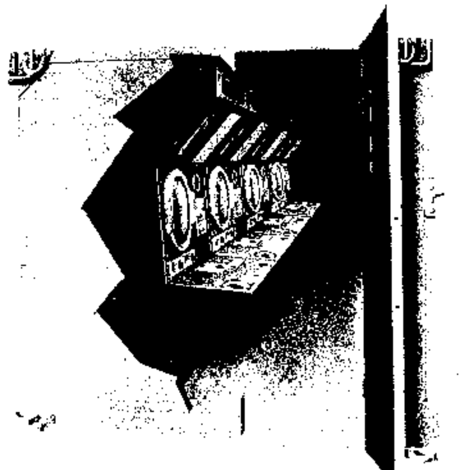
- a radio reception centre stowed in the technical cabin during transportation, an air conditioning unit for the 2 cabins, a CPU

The main characteristics of the cabins are:

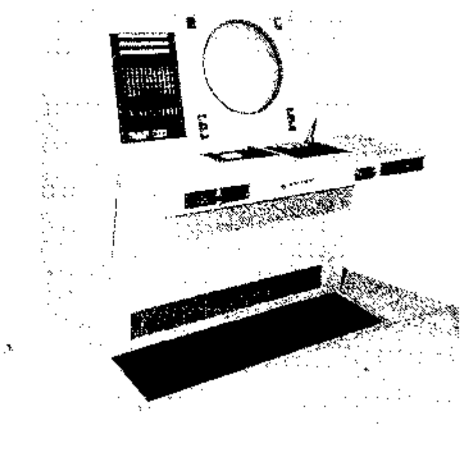
- overall dimensions: 4.1 × 2.5 × 2.1 m,
- weight 2,800 kg approximately,
- consumption: 15 kVA per cabin approximately.

The use of modern technology has made it possible not to sacrifice any of the power and flexibility of the processing and display equipment required. All the equipments are derived from those used in the most recent centres (VISU IV generation) of the French Air Defence Systems STRIDA:

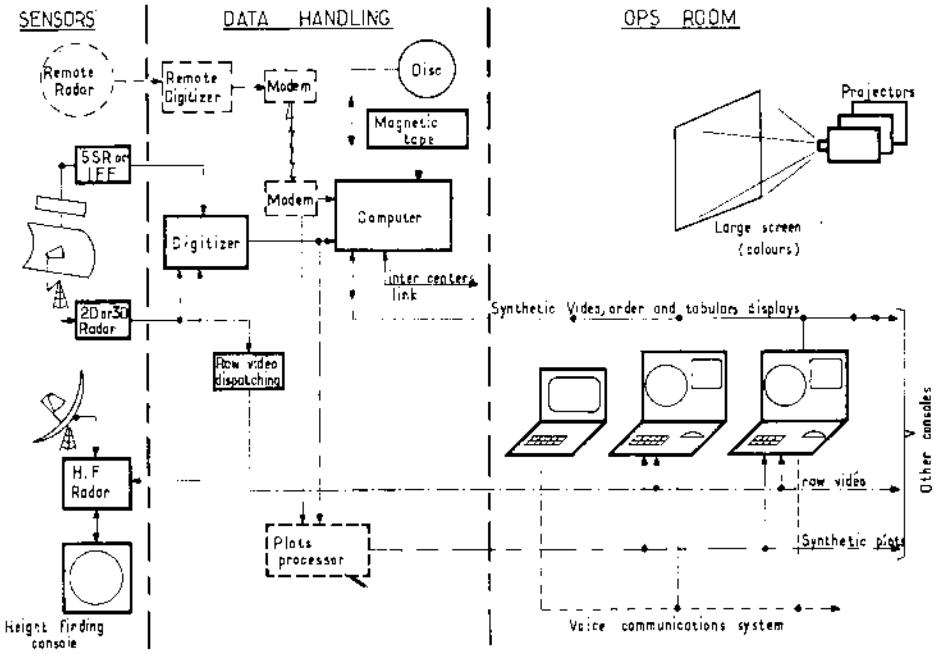
- medium power data processing system used in a bi-processor configuration and suitable for expansion (the memory capacity can reach 224 K bytes),
- comprehensive display system in which each position includes a PPI, Plan View Display screen, an alphanumeric screen, a complete set of keyboards (selection, order and alpha-numeric keyboards) and a rolling ball. The display system incorporates its own refresh memory providing a very large display capacity without overloading the processing system or the link between this system (located in the technical cabin) and the display equipment (in the operations cabin).



MINISTRIDA operations cabin



A MINISTRIDA display console



MINISTRIDA – schematic diagram

EXTENSIONS OF THE BASIC STATION

The possibilities of the basic station can be expanded in several ways:

- by increasing the processing capacity, principally by switching to 100-track processing,
- by increasing the number of controller positions from 4 to 5 positions in the cabin,
- by increasing the number of operational cabins: the station can include up to 3 operations cabins each housing 4 consoles.
- by extending the functions to permit interstation track transmission and to form networks (groups of interconnected stations)

Because of the modularity of the processing and display equipment and the programmes, all these extensions can be implemented without detracting from compatibility with the basic version in any way.

FIXED-POSITION GROUND CENTRES

The system can be built as fixed-position installations. The display facilities can be extended considerably and displays can be presented in colour on the consoles or on large screens.

The system can be built into a network of stations with Reporting Centres, Control and Reporting Centres and Combat Operations Centres. These systems use mainly the same elements as the mobile stations, but the elements are laid out differently.

DEVELOPMENT

The system has been developed by SINTRA on a French Government contract. The contract is administered by the Service Technique des Télécommunications de l'Air.

The system entered into operational evaluation by French Air Force in 1973.

MANUFACTURER:

SINTRA – 26, rue Malakoff 92600-Asnières France.

2161.181
STRIDA AIR DEFENCE SYSTEM

DESCRIPTION:

STRIDA is the French Air Defence Data Processing and Presentation System. The system consists of a network of stations covering French territory with the following main functions:

- detection and identification of aircraft moving in French air space,
- threat evaluation and transmission of alerts.
- In particular, the air situation is centralised and synthesised in the Operational Command of the Air Defence (CODA),
- weapon selection, engagement and intercept guidance. This function obviously implies updating of availabilities and interconnections with air bases.
- control of operational military flights and training flights,
- coordination with the Air Traffic Control system to ensure identification and spacing of operational military flights with respect to general air traffic.

HISTORY:

Studies for the STRIDA system began in 1956 under the responsibility of Service Technique des Télécommunications de l'Air (S.T.TA)

The first stations were fitted with specialised IBM/CAPAC computers and SINTRA VISU II and later VISU III consoles. They have been in operation since 1963. Beginning in 1965, the French Air Force carried out experiments on a new gene ration of stations fitted out with standard IBM Series 360 and later 370 computers and a SINTRA VISU IV display system. These stations are currently in series production phase.

DEPLOYMENT:

The STRIDA system consists of a group of stations in which the control functions (weapon selection, intercept guidance, flight tracking) are decentralised. The interconnection of the centres is carried out in such a way that the automated network is immediately reconfigured in the event of any one of the stations failing.

The system exploits signals from 2 D (23 cm), 3 D (Palmier) and height finding radar (nodding beam or SATRAPE type electronic scan radar) manufactured by TH-CSF.

The Detection Centres are either separated from the Control Centres or incorporated in them. The most complete "CDCS" centres combine detection, control and sector command functions. The CDCS transmit their data to a single Air Defence Operational Command which collects all information on air defence at national level and sends it to the Command (presentation on large AGEC screen).

The STRIDA network is connected to the NADGE network (**1181.181**) to the 412 L (**2533.181**) and to the LINESMAN (**2443.181**) to provide total coverage of Western Europe. It is also connected to the ATC CAUTRA system to permit coordination between military and civil control.

COMPOSITION OF A STATION:

The processing and presentation equipment of a CDCS station mainly consists of:

- an EMIR radar data extractor using a programmed extraction concept,
- a high power processing system using series 370 computers in the stations produced currently,
- a display and control system incorporating from 20 to 30 operational positions (see below).

In some centres, special equipment is found:

- in the Air Defence Operational Command, there is a large AGEC display screen,
- In a centre for controller training, there is a piloted moving aircraft simulator (SAC-HA) delivering a video signal incorporating simulated echoes corresponding to piloted moving aircraft.

OPERATIONAL POSITIONS:

Each operational position or console designed for one controller and his assistant comprises:

- a plan view display screen for presenting raw video (local radar raw video) and data generated by the processing system (synthetic video). This screen presents a synthetic view of the air situation (mainly tracks). A 16-inch diameter screen is used,
- one or several monochrome or polychrome screens measuring diagonally from 5 to 14 inches (up to 4,000 characters displayed) for presenting detailed information on certain subjects (tracks, intercepts) or data received in alphanumeric form (operational availabilities, flight schedules),
- keyboards and a rolling ball (or a joystick) for compiling orders, entering data, selecting the data presented,
- control keyboards or units for communications (radio, telephone, interphone) and for presenting secondary radar data.

MANUFACTURERS:

The system was designed and built for the French Air Force under the direction of the Service Techniques des Télécommunications de l'Air. The main manufacturers who participated in the design and production are:

- IBM France – Division des Systèmes Spéciaux et Militaires – 36, Avenue Raymond Poincaré – 75116 – Paris: extractor, data processing system, programming.
- SINTRA 26, Rue Malakoff - 92600 – Asnières display, operational positions, large screen display, simulator.

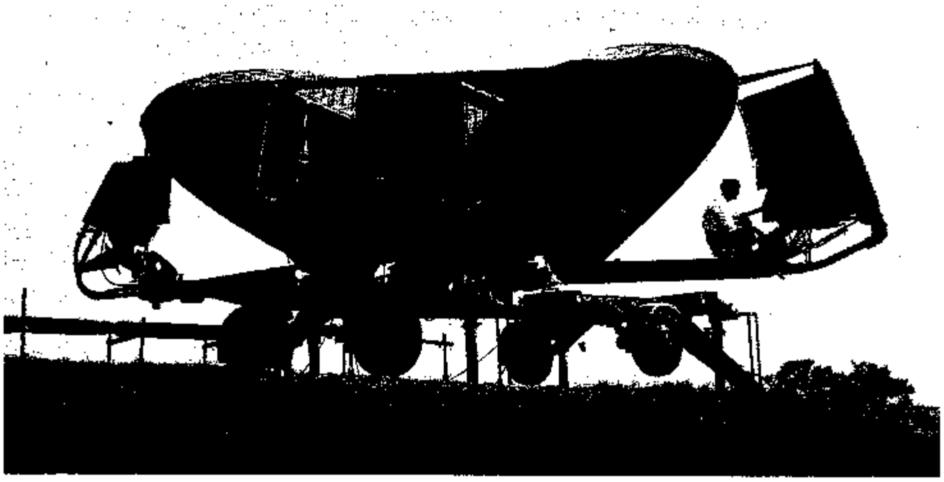
IRAN



Marconi mobile tactical surveillance radar of the type believed to have been specified by Iran

2199.181
AIR DEFENCE SYSTEM
DESCRIPTION:

A substantial radar network is being constructed as part of a United States Military Assistance programme. When complete the Iranian radar network will provide coverage to the North and West and over the Persian Gulf. It is believed that the network includes Westinghouse AN/TPS-43 transportable S-band 3-D radars (**2517.153**). Prior to the commencement of this programme, the Iranian early warning system consisted mainly of AN/FPS-88 surveillance radars (**2512.153**) supplied under CENTO auspices some years previously as part of LORIDS (Long-Range Iranian Detection System) and located around Tehran, Mashad and Tabriz.

It is expected that the next step will be the installation of an integrated command and control system that will bring this radar and communications network and the expanded Iranian ground and airborne defence forces all together in a comprehensive air defence system. Included in this system, it is assumed, will be equipment supplied against a large order for radars, displays and computers which was placed with Marconi Radar Systems in mid 1970.

This order covered the supply of complete mobile systems including power generators, workshop vehicles, spares vehicles and personnel carriers as well as the operational data acquisitions data processing and communications equipment. The primary radars are believed to be the high-power S-330 surveillance and S-404 heightfinder radars originally developed to meet a British Army requirement: the computers were Myriad is as used in the Australian Hub Cap system (**2016.181** and see also **1437.063**).

The programme for the integration of all the radars into a semi-automated air defence system bears the designation **Peace Crown** but it is not known that definite arrangements have been made for its implementation – though there is little doubt that they will be. Late in 1972 a prediction of $30 million of potential business in this area was made by an official of Hughes Aircraft.

It is understood that when the programme is complete it will link up most, if not all, of the increasingly extensive anti-aircraft missile forces with the radars and, by tying into the Imperial Iranian Air Force's **Peace Sceptre** communications system – which covers all the IIAF's air defence sites – form a most comprehensive countrywide system.

ISRAEL

2226.181
AIR DEFENCE SYSTEM

A computer-controlled air defence system has been installed in Israel. It comprises a main control centre and a number of control and reporting centres. No details of the equipment are available, and it is believed that no public statement regarding the existence of the system has been made by either the Israeli authorities or the prime contractor, but it appears to be generally accepted that Hughes Aircraft Company were awarded the contract after completing a study for the new system and it is also understood that the system is based on the TPS-43 Westinghouse radars (**2517.153**) already purchased by the Israeli authorities. It is believed that the data-processing system used is substantially similar to, and uses the same language as other Hughes systems – such as NADGE (**1181.181**) and Florida (**2373.181**). The system is believed to be operational.

ITALY

2250.131
SPADA SHORT/MEDIUM RANGE AIR DEFENCE SYSTEM

DESCRIPTION:

Spada is an all-weather, short reaction time point/area missile system designed to defend relatively small strategic areas (airports, harbours, factories, bridges, rail junctions etc) from low and very low altitude attacking aircraft flying singly, in close formation or sequentially. The system is designed to inflict severe losses on such aircraft even when they are taking advantage of terrain masking and making use of sophisticated ECM devices.

Designed to employ semi-active homing missiles, and particularly the Aspide IA (**1656.331**) missile now in advanced development under an Italian Government contract, the system is modular in concept and its configuration can be adapted to optimize its deployment according to the nature of the surrounding terrain of the targets and of the threat.

SYSTEM DESCRIPTION:

The Spada system comprises the following principal sub-systems:

an Operational Control Centre (OCC), including automatic data processor and display sub-system;

a number of Detection Centres (DC), each including a low coverage search radar, IFF equipment and associated data processor;

a number of Firing Sections, each including a tracking/illuminating radar, a number of missile launchers and semi-active homing missiles.

The number and deployment of these units will depend on the threat density and characteristics. The types of possible configurations range from the maximum deployment, including the Control Centre, Detection Centres and Firing Sections, down to the simplest configuration making use of a single Firing Section.

OPERATION:

The Detection Centre performs the detection, local identification and target data updating, and is connected via a two-way data link to the Operational Control Centre whose tasks include data correlation, local/ADC, identification acknowledge, threat evaluation, target allocation and designation and fire control. The Operational Control Centre is connected via two-way data links to Air Defence Centres (ADC) and to the Firing Sections. The Firing Section performs target acquisition, tracking and illumination, computes the missiles pre-launch data, launches the missiles and carries out the kill evaluation.

When the target area configuration allows for the use of a single DC, this centre is connected directly to the Firing Sections and ADCs and performs the OCC functions in addition to its own.

Isolated Firing Sections are able to perform autonomous search and fire control in addition to their normal functions. This same capability can also be used as a reversionary mode in case of failure of the data link to the OCC.

The system is designed for easy transportability (road, rail or air transport) and for quick deployment.

DEVELOPMENT:

Feasibility studies, as well as system design and computerized simulations have been carried out under an Italian government contract. A prototype is under development and will be delivered to the Italian Armed Forces for evaluation in 1974.

MANUFACTURERS:

Systems and Ground Equipment:

Selenia, Industrie Associate SpA, Via Tiburtina Km 12,400 Rome, Italy.

Missile:

Selenia, Rome; SNIA Viscosa, Rome; Microtecnica, Turin; Elsag, Genoa; Nuova Saca, Brindisi.

JAPAN

2253.181
BADGE – AIR DEFENCE SYSTEM
DESCRIPTION:

BADGE – Base Air Defence Ground Environment – is a computerised air defence system designed to provide the information gathering data processing and display functions required for umbrella protection against aerial attack on Japan. The system comprises radars that will automatically detect, track and identify airborne targets over Japan and a large area of the surrounding ocean; computers to process the radar data and evaluate threats; and other computers to process and furnish data on weapon availability, intercept geometry and related measures, all of which is displayed, together with the processed radar data on complex displays to the appropriate interceptor or missile controllers.

This $56 million system was largely built in Japan for the Japanese Self Defence Force. The prime contractor was the Hughes Aircraft Company of the USA and they supplied much of the equipment of the first installation as well as being responsible for system and equipment design. Most of the subsequent manufacture, however, was carried out by Japanese manufacturers.

BADGE is similar in many respects to ADGE (**2211.181**) and Florida (**2373.181**) and reference may be made to the latter for more detailed information.

MANUFACTURERS:
Prime Contractor: Hughes Aircraft Co, Fullerton, California USA
Japanese Manufacturers: Nippon Aviotronics, Nippon Electric.

2256.181
SECOND GENERATION AIR DEFENCE SYSTEM

DESCRIPTION:
Some time ago it was reported that the Japanese authorities were considering an extension to the BADGE system (**2253.181**) which would both increase its coverage and provide for the integration of the Japanese Hawk and Nike Hercules surface to air missile batteries with the existing defence system.

It was then understood that there were likely to be five phases to this operation although the precise order was not known. The phases were:-
(a) Updating and expanding BADGE to improve coverage of the main Japanese islands.
(b) Linking BADGE to the Nike/Hawk batteries via the JAN/TSQ 51B distribution systems then being built by Nippon Electric under licence from Hughes.
(c) Developing an airborne early warning system.
(d) Further extending BADGE to cover other key areas such as Okinawa.
(e) Introducing improved (three-dimensional) radars for BADGE to replace the FPS 20 surveillance radar (**2528.153**) and FPS-6 heightfinders (see **2523.153**) then used.

STATUS:
We first reported this programme in the 1972/73 edition of this book, and late in 1972 an official of Hughes Aircraft estimated that there was a potential of $20 million of business in computerised air defence radar systems for Okinawa. Since then nothing definite has been heard of this project - which could in any case proceed to some extent on a piecemeal basis.

NATO

1181.181
NADGE - NATO AIR DEFENCE GROUND ENVIRONMENT
DESCRIPTION:
This is a multi-national programme involving 14 NATO countries (so far as funding and contracts are concerned) in the updating and co-ordination of the air defence systems of nine European members of NATO. They are Norway, Denmark, W. Germany, The Netherlands, Belgium, France, Italy, Greece and Turkey. The British air defence network interfaces with NADGE. French participation is limited to use of, and contribution to the reporting and control functions, and that country's defence forces will not be directed against hostile targets by NATO.

NADGE, which is now fully operational, was conceived not as an entirely new air defence installation, but rather as an overall plan for the improvement of some existing hardware and the provision of new equipment in certain areas either to fill gaps in the pre-existing systems or to improve their performance. NADGE represents, in scale, about 20 per cent of the existing NATO investment in European air defence. The cost of the operation has been approximately £120 million.

Funding of the project was based upon a balance of payments system aimed at providing work for the industry of each participating country in accordance with its contribution to the total programme cost.

Estimated contributions are as follows:-

USA	31.83%	Netherlands	3.74%
W. Germany	19.5%	Denmark	2.45%
France	11.7%	Norway	2.31%
UK	11.24%	Turkey	1.07%
Italy	5.82%	Greece	.65%
Canada	5.12%	Portugal	.27%
Belgium	4.13%	Luxembourg	.17%

Precise details of the equipment included in the project have not been revealed, but it is understood that the following equipments form part of the system.

US 412L System Units (AWCS, QUICK-DRAW) (GE). Updated FPS-88 3-D radars (ex Marshall Aid) (GE) Strida II units.

ADGE/IPG units (see below)

Thomson CSF TH.D 1955 3-D radars (**2155.153**).

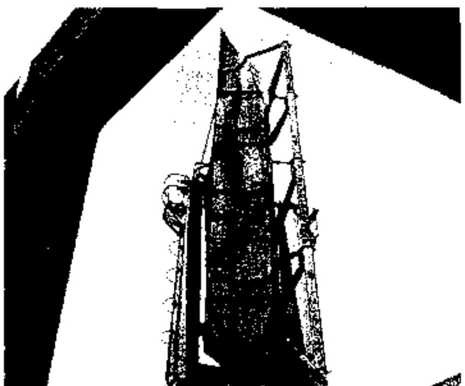
Marconi nodding height finders and 2-D surveillance radars (type unknown).

In addition the system contains considerable amounts of new data-processing, display and data communications equipment. Improvements to existing radars include the addition, where necessary, of video extractors; and there has been considerable emphasis on ECCM equipment.

Taken as a whole, the system is designed for air

Artist's impression of the radar coverage provided by NADGE

An Anglo-Dutch gap filler search radar under test by Marconi Radar Systems in Britain. The aerial and turning gear are made by N.V. Hollandse Signaalapparaten and the associated electronics equipment is by Marconi. This radar is located at two NADGE sites



A Marconi S269 heightfinder radar undergoing test at the Marconi test site. 14 of these radars are installed in NADGE defence against aircraft flying at heights up to 100,000 ft (30,480 m). There is no provision for the detection and countering of missiles or low-level, sub-radar threats. Against air threats, NADGE is to be used for the control of interceptor aircraft and surface-to-air missiles.

Equipment is arranged in five basic configurations. Every installation contains the equipment necessary for functioning as a Sector Operations Centre (SOC). By the addition of further standard sets of equipment any installation has been expanded where appropriate to operate as one of the following: Reporting Post (RP), Command Reporting Post (CRP), Command Reporting Centre (CRC), or combined CRP and CRC. Each installation is provided with the means of exchange of data from one site to another.

The complete NADGE system comprises 84 sites of which 37 contain data processing complexes. The latter contain multiple general-purpose digital computers for the real-time processing, analysis and distribution of target information from its own sensors, and the correlation of data from other stations received by data links and conventional communications channels.

Advanced data display equipment serves the functions of data gathering (detection, tracking, height-finding, target identification, and target-size analysis); and data utilisation (threat analysis, weapon assignment, and weapon control). Once a target is acquired by radar, the information is transmitted by data link to the Command Reporting Centre, where it first appears on a display console as a conventional target 'blip'. The data is simultaneously transmitted to a video processor which determines whether the blip is a genuine target, enemy jamming, or simply video clutter.

The information is next passed to a correlator, or computer memory unit, the function of which is to generate target tracks for genuine radar returns. These are returned to the original display as synthetic tracks in the form of digitised track symbology. This is superimposed upon the raw radar, providing the operator with two means of tracking the target. Target identification can be accomplished by IFF, voice identification, or by computer comparison of target characteristics. Potential target co-ordinates are transmitted automatically to surface-to-air missiles batteries, and this information is also available at interceptor airfields.

DEVELOPMENT:

Agreement was reached within NATO in the early 1960s that automation and integration of the member countries' air defence systems was necessary to meet the increasing scale and sophistication of the threat, and operation requirements were eventually drawn up. It was decided that the work should be performed by an international consortium of electronics concerns, and calls for bids went out on this basis. None of the proposals which resulted was capable of meeting the requirements within the stipulated costs, and a protracted period of re-bidding and adjustment of the requirement followed. In the final stages there were three consortia contesting the contract. Once more the target cost could not be met, and it was ultimately decided to eliminate some of the more advanced facilities called for in the original specification. The winner of this competition in June 1966, was the Hughes-headed group which subsequently formed itself into an international company called Nadgeco, with headquarters in London.

During the prolonged competition three countries, W. Germany, Belgium and The Netherlands, decided that they were unable to await the completion of NADGE before providing improved facilities for the air defence forces they were already operating, and concluded an agreement with Hughes for the provision of a system – successfully known as TAWCS (Tactical Air Weapons Control System), IPG (Interim Planning Group), and ADGE (Air Defence Ground Environment), which is now integrated into NADGE.

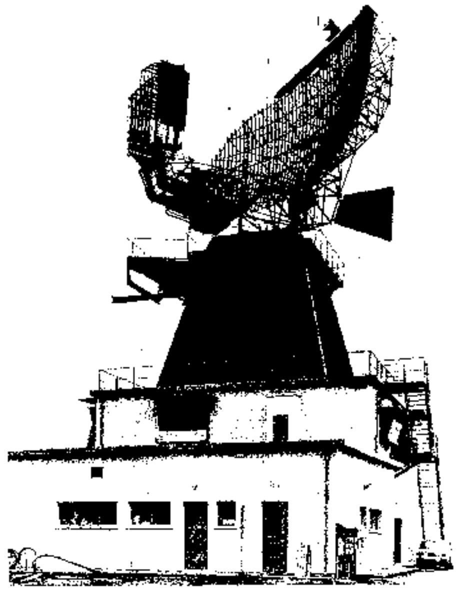
Nadgeco was formed in January 1967 and planning started. This involved the definition of hardware specifications, work schedules, and contractual negotiations with about 140 equipment suppliers, 70 customer authorities, and a similar number of contractors and material suppliers.

STATUS:

Although the system, as first conceived, is complete, except for a large number of administrative and other tidying-up processes which will probably keep Nadgeco busy to the end of 1974, it is generally agreed that there is a need for further extensions. Desirable additions include extension of cover – by the addition of new sites in Italy, Greece and Turkey – to the NATO naval forces in the Mediterranean, addition of low-level coverage, improved links with the UK Linesman system and further updating of some of the older equipments in the system.

Some of this work has already been put in hand. Hughes Aircraft Systems International (HASI) and Advanced Electronic Systems International (AESI), both Hughes subsidiaries, are engaged in a coverage extension programme involving the construction of four new sites and the modification of three existing NADGE sites in Greece. HASI also is upgrading three national air defence centres in Turkey to NADGE standards. Selenia is upgrading parts of the Italian system with HASI as sub-contractor.

Nadgeco as such, however, will be wound up on completion of the end-processes mentioned above. The consortium countries have set up a new organisation called Eutronics, which is based in Brussels, and this will be competing with other potential suppliers both for further NADGE business and for similar business elsewhere.



The first ARES long-distance radar for NADGE in Italy. The radar is manufactured by Thomson-CSF and is among the most powerful in the world

MANUFACTURERS:

The members of the six-nation consortium and their main equipment contributions to NADGE are listed below. There are also numerous other sub-contractors from the other participating countries which are receiving orders in relation to their own country's contribution to the funding of the project.

Hughes Aircraft Company, Fullerton, California, USA: Computers and specialised software.

GEC-Marconi Electronics, Chelmsford, Essex, England: Height-finder radars, improvements to existing radars, height-strength measuring consoles, manual tracking posts and reporting posts.

AEG-Telefunken, Ulm, West Germany: Video link equipment for Norway, Denmark and Turkey, part of the medium-power radars under sub-contract from Thomson-CSF.

Thomson-CSF, Paris, France: Medium-power radars.

Selenia, SpA, Rome, Italy: Data displays and video link equipment for Italy.

NV Hollandse Signaalapparaten, Hengelo, The Netherlands: Gap-filler radars, two-dimensional extractors, display system modifications.

SOUTH AFRICA

2321.181
SOUTH AFRICAN AIR DEFENCES

DESCRIPTION:

Details of South Africa's air defence system are not available. It is known, however, that there is a modern early-warning radar network supplied by Marconi, England, and covering the north-eastern and north-western approaches to the Republic and that this system has its headquarters at Devon in the Eastern Transvaal.

This system is linked to the South African Air Force Strike Command base at Waterklorf near Pretoria at which are located the Command's Mirage IIICZ interceptor and Mirage IIIRZ reconnaissance squadrons. Also located at this base are the Mk 50 Buccaneer squadron when they are not being employed in support of the maritime forces.

The batteries of the Cactus surface-to-air missile system (**2341.131**) which is now in service with the Air Force are also linked to the early-warning system and are assumed to be charged primarily with the defence of Air Force installations.

All these measures are aimed at countering what is to South Africa the obvious major threat of an attack by relatively short-range aircraft based on airfields in the African continent. There appears to be no land-based air defence system designed to deal with an attack from aircraft carriers off the southern coast: presumably the intention is to rely, for the time being at least, on early warning by maritime patrol aircraft and shipborne radar.

SPAIN

2322.181
COMBAT GRANDE AIR DEFENCE SYSTEM

DESCRIPTION:

Combat Grande is the name which has long been associated with a proposed automation of the Spanish air defence system which is now in process of being implemented. The system is being processed by the US Air Force for the Spanish Government and is to be supplied by a jointly owned Spanish-American company registered in California.

The new system will absorb the earlier Spanish manual air defence system and create an automated system of modern design to provide early warning of air attacks and control Spain's interceptor aircraft and Hawk missiles. Operations involved in the programmes include:

(a) development of a combat operations centre and a sector operations centre
(b) an improvement and modernisation programme for seven long-range radars and associated communications equipment
(c) extension of existing microwave link facilities.

It is expected that the modernisation techniques will resemble those applied to some of the older systems which were updated during the NADGE development programme (**1181.181**); and although, so far as is known, there is no definite intention to link the Combat Grande system with NADGE at present, it is a near-certainty that the new system will be so designed as to make such a linking-up operation a simple matter if and when the need is established.

STATUS:

Development.

MANUFACTURERS:

Prime contractor is COMCO Electronics Corporation, a company jointly owned by Hughes Aircraft and the Compañia de Electronica y Communicaciones SA (CECSA). Each of the two parent companies has a 50% holding in COMCO.

Hughes will build the computers and design the communications equipment for the new system. CECSA will manufacture the communications sub-systems and manage the civil engineering construction.

SWEDEN

2350.181
AVISTA AIRCRAFT TRACKING AND DATA-REPORTING SYSTEM

DESCRIPTION:

Avista is the name given to a system for providing radar warning systems with a back-up system based on visual observation.

The idea behind the development of this system is the vulnerability of radar systems to ECM and other interference. While the contribution that can be made by direct visual observation is necessarily limited by darkness or bad weather, the same conditions also impose limitations – albeit less severe – on the capabilities of intruding aircraft. This is a changing situation, and aircraft attack – particularly at low level – in conditions of bad visibility will become progressively more probable as the installation of more sophisticated airborne equipment progresses; for some time to come, however, there will be a significant contribution that can be made by an organised visual detection and data reporting system.

The essential characteristics of such a system are that it be capable of covering a wide area of territory – because visual ranges are short – and that it be capable of reporting accurately and rapidly to the control centres that otherwise are served by radar. Since many observation posts will be required to satisfy the first requirement the system, to be a practical proposition, must employ low-cost equipment; satisfaction of the second requirement calls for an effective and accurate telemetering system coupled with terminal equipment that can rapidly translate the multiplicity of reports into a readily intelligible form.

In the Avista system observation posts, spaced up to 20 km apart, are equipped with data transmitters by which information on the bearing of observed aircraft is transmitted rapidly by telephone or by radio transceivers to SOC's. In the SOC the information is presented on a map by means of lamp displays in such a way that the observed aircraft gives rise to a lighted track. When telephone network transmission is used, three observation posts can share one telephone line without mutual interference. Normally, the aircraft is displayed on the map 5 to 10 seconds after the observation is made.

MANUFACTURER:

AGA Aerotronics AB, S-181 81 Lidingö, Sweden.

2358.181
STRIL 60 AIR DEFENCE SYSTEM

DESCRIPTION:

STRIL-60 is a fully automatic air surveillance and operations control system operated by the Swedish Air Force.

Inputs to the system come mainly from radars – both air surveillance and coastal radars – but a back-up visual reporting service is included to supplement the radar data and to replace it if the radar input is blocked.

Information from all these sources is fed into a central data store; whence it is extracted for selective presentation to controllers having specific functional responsibilities and/or specific territorial assignments.

OPERATION:

When a threat is detected the STRIL-60 controllers, who also have available to them state-of-readiness information on available forces and weapons, decide with what kind of available weapon the threat can best be countered and assign that weapon to the task. In appropriate cases – for example, surface-to-air missiles – they will also control the operation. Currently the forces controlled by the system are the SAAB Draken interceptors (to be replaced from 1978 by the JA37 Viggen) and six squadrons of Bloodhound 2 surface-to-air missiles (**2406.131**).

The STRIL-60 centre is also linked up to the civil defence organisation, and can both alert them and warn industry or the civilian population.

If the threat cannot be countered by the forces under the control of one centre but can be countered by those of another centre, the system provides both voice and video transmission links for giving information to other centres.

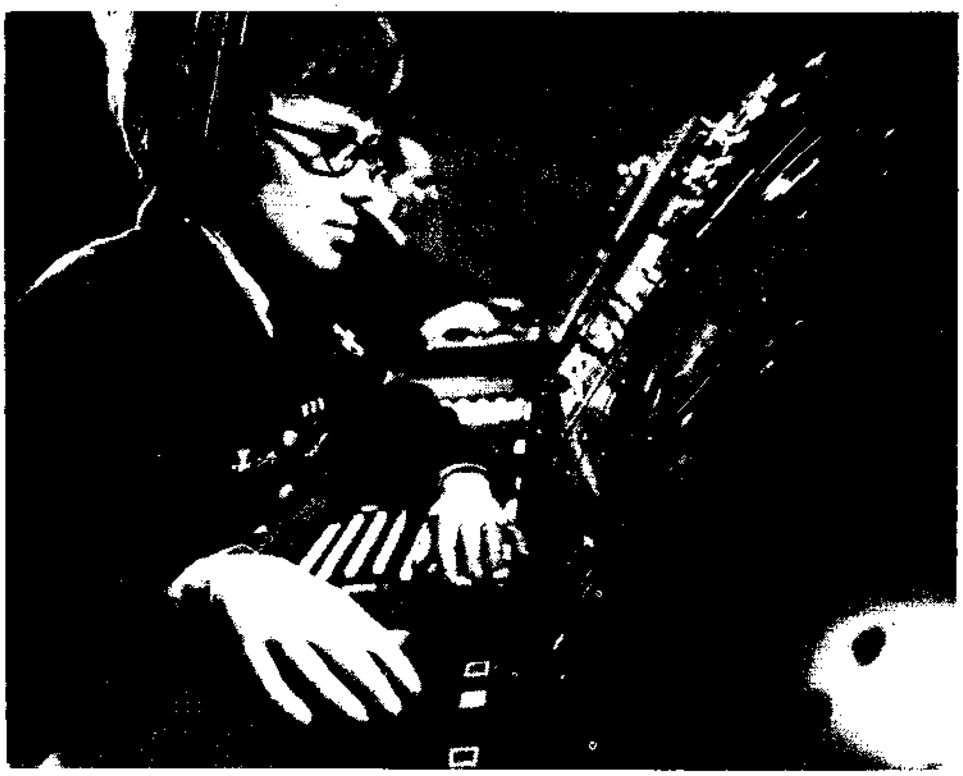
Although primarily an air defence system STRIL-60 is linked to coastal as well as to anti-aircraft artillery.

STATUS:

STRIL-60 is currently an operational system. It is expected, however, that in the near future a major overhaul and updating programme will be put in hand – probably by the newly formed ITT Telekommunicatione – a company jointly owned by ITT, SAAB and the Swedish Government.

MANUFACTURERS:

Prime contractor for the system was Standard Radio & Telefon AB, (SRT), Bromma, Sweden. SRT were also responsible for the creation of a similar system in Denmark.



Operators at work with Standard Radio and Telefon displays at a Swedish air defence centre

SWITZERLAND

2373.181
FLORIDA AIR DEFENCE COMMAND CONTROL SYSTEM

DESCRIPTION:

FLORIDA is the name given to a computerised air defence command and control system that was accepted and declared operational by the Swiss military authorities in April 1970. General contractor for the system was the Hughes Aircraft Company.

DESCRIPTION:

The system consists of several military radar stations with 3D radar and air defence direction centres, including computers, display consoles and associated equipment. Information from the radar station is fed into conversion equipment in underground Air Defence Direction Centres and processed in turn by a high-speed Hughes general-purpose computer.

This computer automatically establishes speed, heading and altitude of an unidentified intruder. Display consoles present a constantly updated picture of the aircraft's flight track as well as information on the various weapons available, their launch ranges, velocities, armament, restrictions and time-to-k .

Should the target be identified as an immediate threat, the air defence commander can electronically request all-weather interceptor aircraft or surface-to-air missiles to intercept and destroy, and can a ert the c vil defence organisation.

SYSTEM COMPONENTS:

The radar used is a long-range three dimensional radar, with a planar array aerial using the Hughes elevation frequency scanning technique. This provides simultaneous range, bearing and altitude data. An FF system s associated with the radar.

The system includes video extractors that analyse radar returns, with the help of a real-time computer, and extract actual aircraft tracks from spurious returns such as clouds and ground returns. Track acquisition and updating is automatic.

This processed information is fed to Air Defence Direction Centres where it is accepted by a computer. This takes in information from the missile sites, airfields and other military installations and stores it for use in se ecting defensive measures.

It can also simulate air battle situations for training and instruction, and can be used as a general purpose data processing centre.

The computer may be required to provide information on weapons available, their launch ranges, velocities, armament, restrictions and time-to-ki... Numerals and symbols are used to provide this intelligence to the contro er and to depict the battle area, the threat and the defences, the problems and their solutions. The computer, the Hughes H-3324 is of the same type as those associated with the radars but has a much larger storage capacity. Typically it might be called upon to execute between 50,000 and 550,000 instructions in a second.

In the Direction Centre the display consoles are arranged to display only that information which is pertinent to the tasks of the operator concerned. The principal functions are:

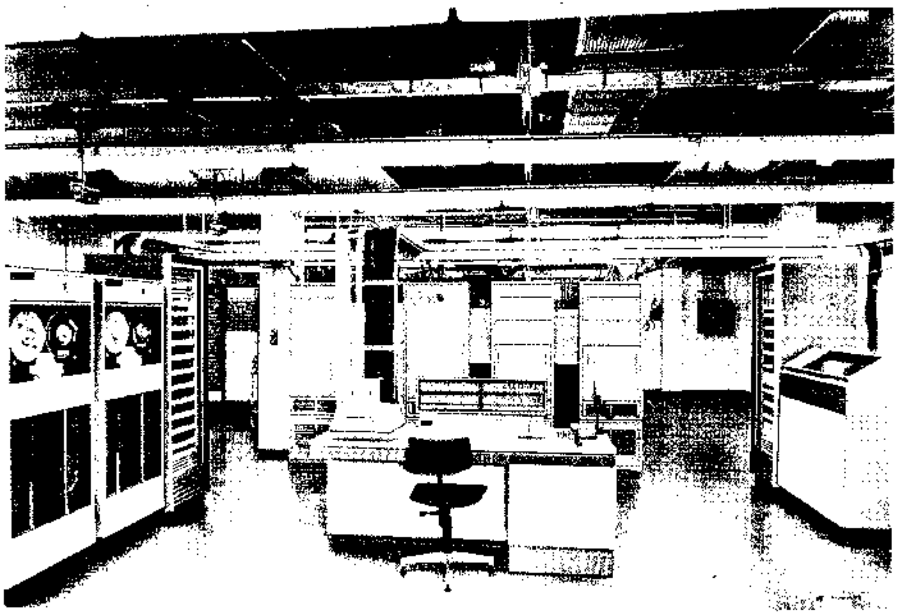
Identification officer responsible for designating radar tracks as friendly or hostile aircraft.

Interceptor director – interested in his own controlled interceptor and the assigned hostile aircraft. To him, specific data about this intercept is presented including attack geometry, altitude, speed, time to intercept, etc.

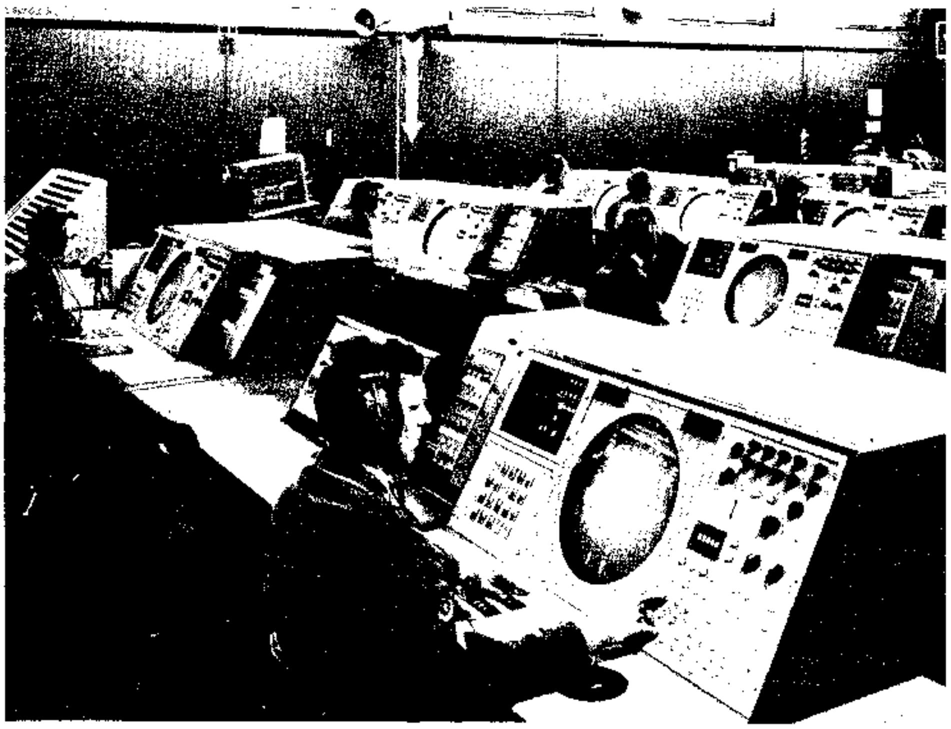
Air traffic coordinator – concerned with military aircraft requesting clearance to cross civilian airways.

Missile officer – (surface to air) in close contact with the missile batteries and assigns targets to the appropriate site.

Chief of air defence concentrates on deployment and the threat. Total composite air situation and threat boundaries are important to him.



Computing and data handling centre for the Florida system



The display console used in the Air Defence Direction Centre

Aircraft and missile forces currently under control are two Mirage III S interceptor squadrons and two Bloodhound 2 surface-to-air missile battalions (**2406.131**). There are also 45 batteries armed with Oerlikon twin 35 mm cannon.

DEVELOPMENT:

The contract for Florida was let to the Hughes Aircraft Company in January 1966 following preliminary negotiations in the previous year. The contract required Hughes to design, build, install and test a semi-automatic air surveillance and guidance control system for military aircraft. System acceptance by the Swiss authorities was to take place after Florida had been integrated into the Swiss air defence system and verified by a lengthy test process. It is this process that had been completed when the system was declared operational in April 1970.

HUB CAP DEVELOPMENTS

Hub Cap is a sophisticated mobile control and reporting unit (CRU) for air defence designed by Plessey and based on a specification written in close collaboration with a team of Royal Australian Air Force officers. It is currently deployed in Australia and is described in entry **2016.181**.

NEW DEVELOPMENT:

Technological advances have enabled considerable reductions in size and weight to be made on such systems as Hub Cap, while still retaining the capacity and facilities of the latter.

A modular display and data handling system has been evolved by Plessey which can be deployed to meet a variety of operational requirements. It may be used in a static or mobile role and is designed in modular form to allow the facilities to be readily expanded.

Modules are built into transportable cabins, each of which weighs less than 1,800 kg and occupies approximately 10 cubic metres. The system is designed for transport by helicopter (slung) or freight carrying aircraft (such as C130), and can be transported by road vehicle, road mobiliser or train.

From a single module two or three manual interceptions can be performed with the assistance of manually initiated automatic tracking or rate aiding facilities. Track information is presented as a prediction vector on the controller's display, along with digital read-out of height and identity. This intercept capacity can be increased by adding a second display module and/or automatic data processing module to give, for example, computer aided interceptions, 100 tracks, and other facilities such as strike, flight following, etc.

Initial mobility trials have already been carried out, and the time into action of a typical system is estimated as less than one hour.

To enable the operational capability to be matched to the particular air defence need and to the available transport, the system has been arranged so that a phased build-up capability or system re-configuration can be readily implemented in the field.

The accompanying block schematic diagram shows a typical mobile tactical data-handling system.

LINESMAN AIR DEFENCE SYSTEM

DESCRIPTION:

Linesman is the code name given to the military part of the joint civil/military complex of radar data-processing and display equipment known as Linesman/Mediator. Until recently it was the principal focus of the British air defence system.

Linesman was originally conceived as an anti-bomber defence supplementing the anti-missile defence – such as it was – provided by BMEWS (**2525.181**) and the United States' capacity for 'massive retaliation' at the time when the NATO strategy was based on the 'tripwire' concept. Before the system came into operation, however, both the NATO policy and the nature of the threat changed; as a result there has been a gradual evolution in system thinking while the people and equipment of the system have been more concerned – in practical terms at least – with anti-reconnaissance and anti-ECM operations than with preparing to intercept what appeared to be an unlikely medium-level or high-level bomber offensive.

Broadly speaking, the main elements of the system and of its associated systems are, first, a set of radars peculiar to Linesman and intended for use as main data input devices; secondly, a further set of early warning and data handling devices – the Standby Local Early Warning and Control (SLEWC) Centres – whose function was to supplement the primary air defence system and at the same time offer the possibility of independent operation in the event of a system failure; thirdly, other radars in the joint military/civil complex whose outputs were processed by both parts of the combined systems; fourthly, inputs from the NATO long-range radars and the NADGE network (**1181.181**). The UK network is not in fact a part of NADGE but there are close links between the two systems.

Processed data from all these inputs was supplied – in appropriate form – to the RAF Strike Command HQ and to the joint civil/military control centre at West Drayton. It was at Strike Command that a decision was taken to intercept, for example, an unknown intruder into British airspace; but it was at the West Drayton control centre that the tactical controllers were located and it was these controllers who had the task of controlling the aircraft or missile formations engaged in any particular operation once it had been initiated by Strike Command.

As a result of internal evolution and external criticism of the system the whole Linesman concept can now be regarded as having been eliminated from the UK air defence system. It has been replaced by what is to all intents and purposes a new system (described below in entry **2444.181**) but since the name 'Linesman' is as yet far from obsolete as a general reference description for much of the equipment in the new system it seems advisable to retain a reference to it in the present volume.

2426.181
MARCONI TACTICAL AIR DEFENCE SYSTEMS

Based on the Marconi S600 Series of radars (**1168.153**) and associated equipment, a number of different tactical air defence control and reporting systems have been supplied or are on offer to a variety of customer countries.

A "building-block" approach has been adopted by the manufacturers who offer in particular a number of preferred configurations of equipment – although obviously variants lying outside these preferred configurations can be devised. In order of complexity the preferred configurations are:

(i) Early Warning Post

(ii) Track Reporting Station
(iii) Control and Reporting Station (single surveillance radar)
(iv) Control and Reporting Station (extended cover using two surveillance radars)
(v) Control and Reporting Station (expandable to computer control)
(vi) Area Control Station (full computer control)

Apart from physical limitations due to earth curvature, the absolute range performance of each station is limited by the aerial dimensions and transmitted power available in a transportable system. To offset these limitations it is recommended that a tactical defence system be obtained by integrating a number of elements, each capable of local autonomous control of a limited number of weapons as well as early warning and reporting into a central area control station. The use of several stations has a number of advantages including

(a) wider spread of frequencies to combat ECM
(b) better low cover
(c) greater reliability by overlapping cover thus allowing for the loss of one element at any time
(d) maintenance of overall cover during redeployment of individual stations
(e) smaller stations are inherently easier to redeploy
(f) standardisation of modules eases spares and training requirements

TRACK REPORTING AND EARLY WARNING STATIONS

Track reporting stations, suitable for tactical use in forward battle areas to provide low cover surveillance or for use in a gap-filling role in more extensive systems, can be provided by the smallest configurations. Within the limitations imposed by siting conditions, the radar cover provided by such stations ensures detection of small fighter/bomber aircraft out to ranges in excess of 120 miles and larger medium bomber aircraft to ranges of 160 miles. To obtain optimum performance and minimise problems caused by weather conditions, frequency allocations and geographical features, variants of the S600 range are available for operation on S-band or L-band.

In the basic station the radar responses are displayed on a single 406 mm PPI display unit housed within the transmitter cabin. Track reporting from this position is carried out manually by voice communication over a VHF radio communications link. The PPI incorporates range expansion and off-centring facilities for detailed examination of areas of importance, range markers at 5 or 10 mile intervals and a range/bearing cursor line.

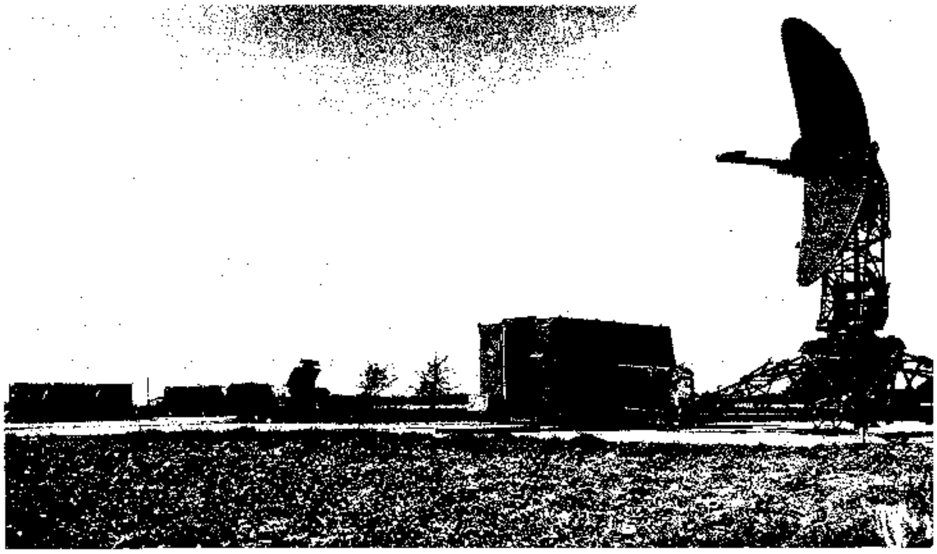
OPERATIONS CABIN

A station of greater capacity can be provided by the addition of an operations cabin type S5013 to the basic track reporting station. This contains three operational displays similar to that in the track reporting station but incorporating semi-automatic track reporting by digital data link. Track positions are precisely marked by electronic markers superimposed on the radar responses, the markers being controlled by rolling ball on the operators' desks. Each operator can maintain up to four tracks simultaneously, giving a total capacity of twelve tracks to the cabin. IFF facilities for identification of aircraft responses may be fitted to any of the variants depending upon the requirement.

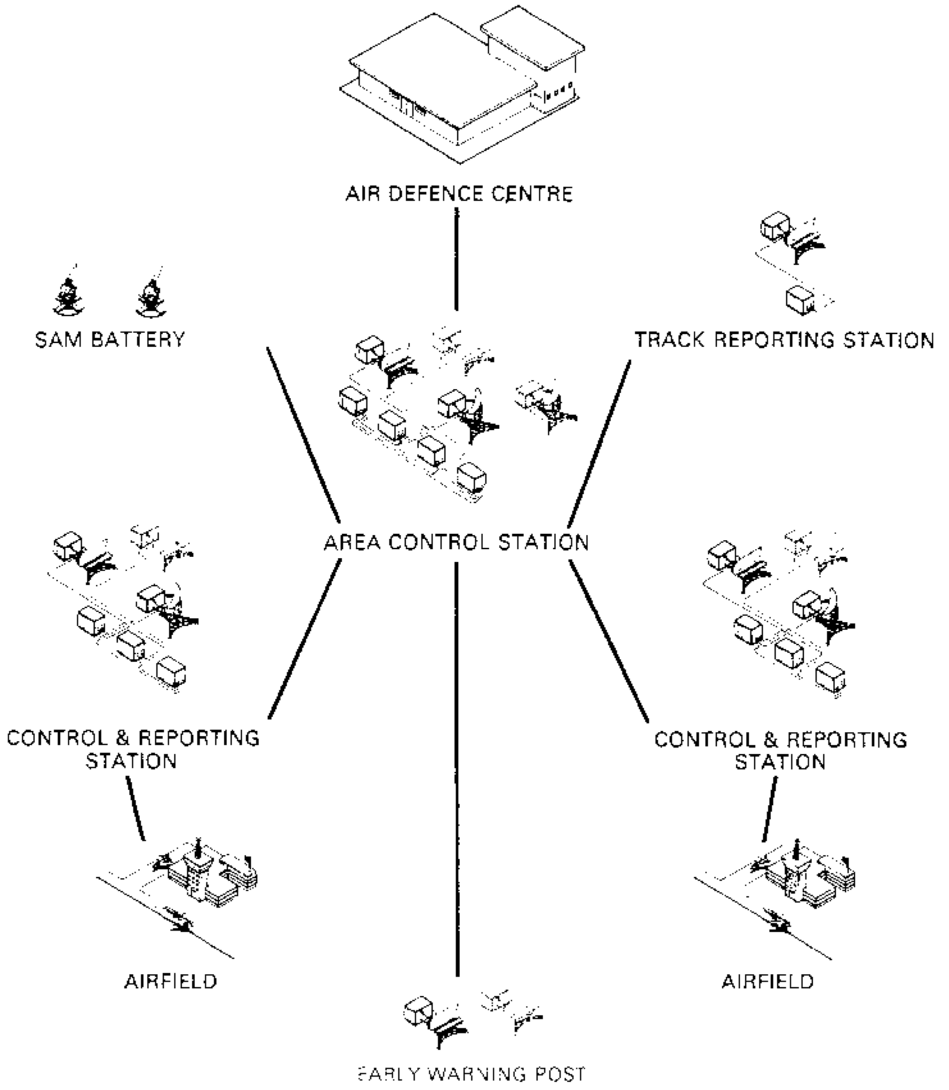
CONTROL AND REPORTING STATIONS

A control and reporting station for ground control of interceptor aircraft and close support strike aircraft in a tactical situation is provided by combining a height finding radar with one or two surveillance radars. Detection of small fighter/bomber aircraft out to ranges of 120 miles and medium bomber aircraft up to ranges of 160 miles is then supplemented by height information of high accuracy. The performance of the height finding radar is matched to that of the surveillance radars. Furthermore the height finding radar has a useful capability in a volumetric scanning role to maintain radar cover in the event of surveillance radar malfunction.

With these radars, one or two operations cabins may be deployed. If it is assumed that the threat



Units of the Marconi tactical air defence systems. Heightfinder in the foreground; surveillance radar with on-mounted IFF aerial in the background



Typical layout of an integrated tactical control system

only justifies deployment of a single operations cabin, then the operational functions may be used in any of the following roles

(a) Primarily in a reporting role, manned by a master tracker and two trackers, increasing under periods of peak activity to three trackers
(b) As an early warning unit with a capability of handling two manual interceptions from one position with track reporting from the two remaining positions
(c) As an early warning unit with a capability of handling four manual interceptions from two positions with "broad brush" reporting from the remaining position
(d) Solely as a control unit capable of handling six manual interceptions from three positions and no raid reporting.

AUTOMATIC DATA PROCESSING

Where a control and reporting station is to be part of a major tactical air defence network, the introduction of automatic data processing techni-

ques is a major factor in reducing reaction time and improving operational effectiveness. For this purpose the type of operations cabin described above may be exchanged for a different type (S5014) in which the 406 mm displays are accompanied by 300 mm tabular displays which operate in conjunction with light-pen modules to give a programme dissected entry panel for communication with a computer. Organisation of the displayed data and interpretation of the light-pen entries from the operators' desks are effected by a smaller processor contained within the cabin. This small processor also gives this kind of system considerable added capacity as an autonomous unit, as well as making it compatible with a central computer. Functions that can be performed include:
(a) Control of the heightfinder.
(b) Inter-console marking.
(c) Track storage for up to 20 tracks.
(d) Transmission of track data to remote sites via digital data link.
(e) Display of relative range and bearing.
(f) Labelled radar display.
(g) Rate aided manual tracking with track smoothing, hopping strobe and automatic sequencing.
(h) Generation of area gate strobe for active SIF code on selected targets; validation of decoded returns and display of code information.

INTEGRATED TACTICAL AIR CONTROL SYSTEM:
For over all cover of a forward battle area an entire air support control complex is necessary. The air defence centre represents the section of field headquarters responsible for over-all command of the air battle. This centre must be in constant communication with the area control station from which executive control of all aircraft is exercised and whose functions include:
(a) Co-ordination of the individual air support control elements within the system.
(b) Assembly, correlation and distribution of data relating to aircraft movements, status of air defence elements and tactical allocations.
(c) Assessment of hostile air activity and allocation of defence elements.
(d) Control of aircraft on interception and strike missions.
(e) Integration of manned interceptors and surface-to-air weapons defence systems.
(f) Feedback of information to the air defence centre.

The control and reporting stations extend the radar cover over wider areas, and in addition to feeding information back to the main centre provide a facility for local control of limited forces engaged in interception and strike functions. If situated adjacent to airhead support bases, the control and reporting stations can also perform a military air traffic control role for all arriving and departing aircraft.

The track reporting stations are the smallest surveillance configurations; these are deployed in forward areas, charged with detection of enemy movements and passing this information up the chain of command for action.

AREA CONTROL STATIONS:
This configuration incorporates extensive facilities, including computer assistance, for full control of the air battle in a tactical situation. A complete air defence system in transportable form becomes available by adopting the S600 Series of Data Processing cabins which are designed to operate in conjunction with the S600 Series radars and operations cabins.

In its fullest configuration the Area Control Station employs:
(a) Two surveillance radars, typically one S-band and one L-band with suitable aerials to give both high cover and long-range low cover.
(b) Two height finding radars giving a data rate of 40 heights/minute.
(c) Four operations cabins providing twelve display positions.
(d) One data processing cabin.
(e) Up to six digital data link terminals for the automatic transfer of data.
(f) Ground-to-air and ground-to-ground communications equipment.

To make greatest use of the available hardware the computer operates with an adaptive programme and the universal display positions allow changes in operational functions to meet differing requirements in a tactical situation. The following data processing services are available in a typical system to meet the demands for tactical air control:
(a) Tracking capacity of sixty tracks, using manual initiation with subsequent automatic track following on data from a plot extractor. All tracks are presented on marked radar displays.
(b) Automation correlation of secondary radar data with tracks for identification purposes.
(c) Flight plan storage for information received from movement control centres.
(d) Display of stored flight plans.
(e) Control of height finder sequence and correlation of extracted heights with track stores.
(f) Threat assessment and weapon assignment for allocation of interceptors and for missiles.
(g) Trial intercept calculations and control of fighter aircraft for up to sixteen simultaneous engagements.
(h) Calculations for recovery of up to twelve aircraft simultaneously.
(i) Calculations for planning and controlling aircraft on strike missions.
(j) Simulation of target and fighter tracks for training exercises.
(k) Data recording for assessment of operational efficiency.
(l) Video indication of selected airfields and beacons.

Each display position may be programmed to perform any of the designated operational functions and the system may be re-structured by programme change to overcome the loss of service from any position. Intercommunication equipment is provided to link all positions for voice contact. Also, each position is connected by an electronic pointer facility for hand-over of positional data observed on the p.p.i. displays. Ground-to-air and ground-to-ground communications connections are available in each cabin and can be selected by operators and controllers as required.

STATUS:
Available. Various systems have been supplied to customers outside the UK but details are not available for publication.

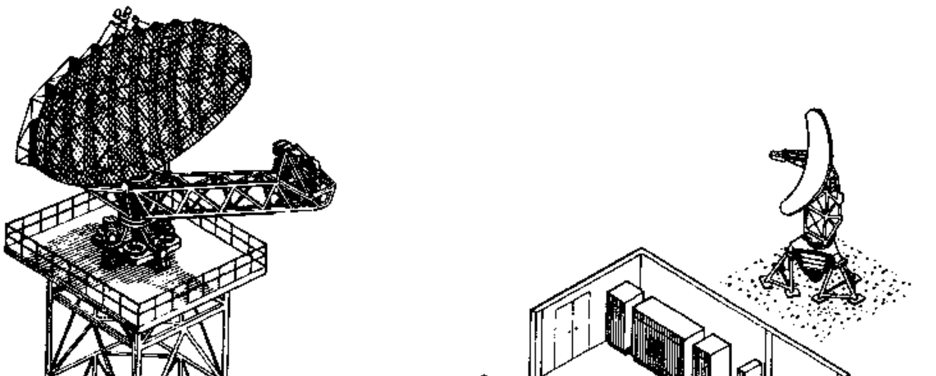
MANUFACTURER:
Marconi Radar Systems Ltd, Chelmsford, England.

2429.181
MARCONI STATIC AIR DEFENCE SYSTEMS

DESCRIPTION:
Static air defence systems manufactured by Marconi are based on the same general principles, and the company offers equipment reflecting the same modular approach to the problem as in their tactical systems (**2426.181**). Indeed, for the simpler types of installation the basic equipments used may well be the same; in which case the differences are likely to reside only in the substitution of permanent structures for mobile supports, cabins, cableways and the like.

For more sophisticated systems, however, the designers of a static system can take advantage of the wider range of equipment that becomes available when the mobility requirement is dropped. As examples of such complexes there are considered below: a limited capacity control and reporting station, an area control station and an air defence operations centre.

Control and Reporting Station – limited capacity
A control and reporting station for ground control of interceptors could be provided by combining an S637 heightfinding radar with one or two S600 series surveillance radars. For example, using an S654 L-band 2mW dual-beam surveillance radar with the 1mW heightfinder it should be possible to detect small bombers out to 150 nm and medium bombers out to 200 nm and to determine their heights with an operationally sensible degree of accuracy. The suggested combination uses two radars that are well matched in performance so that heights should be obtainable on all aircraft detected; furthermore the



Arrangement of a control and reporting station heightfinder can be used for volumetric scanning if the surveillance radar is out of action.

A high ECCM capability is achieved by the use of two frequency bands (L and C), by the low side-lobe level of the two aerials and by the use of anti-jamming receivers and signal processing.

This configuration is adequate where the threat is limited. In this situation it is capable of a stand-alone role and for this purpose is equipped with two three-display console suites. General situation assessment is achieved by plotting on a vertical edge lit perspex general situation map from track data supplied by two trackers, with the third position on the console suite allocated to a master tracker who is also responsible for the identification of tracks.

The other three-display suite is manned by a chief controller and two interception controllers who direct the interception and recovery of the fighters to base through u.h.f. or v.h.f. ground-to-air radio links. A communication system also links the operator positions to each other and to fighter bases and other remote units of the defence organisation.

All positions obtain height data through demands made by a tracker ball control which actuates the automatic height extraction equipment. The same marking system is also used to obtain relative range and bearing information and to 'point' between operational positions.

Area control station

In situations where it is desirable to exploit the full long range high cover capability of large static aerial systems and in order to provide a pivot for a complex air defence system extending over a large geographical area, a more complex configuration of equipment is appropriate.

Alternative primary radar systems are available to satisfy this requirement.

1. 2D fan-beam surveillance radars, with single or back-to-back dual frequency aerial systems in conjunction with one or more nodding heightfinder radars.
2. 3D multi-beam volumetric radars. The choice between these alternatives is made by consideration of the operational requirements of the air defence organisation. Each has advantages and disadvantages which influence the choice in a particular situation, but, broadly speaking, the 3D volumetric system is considered appropriate where high traffic densities occur.

The processed signals from the surveillance radar system are fed into primary and secondary radar plot extractors, whereby all valid plots are expressed as digital quantities and correlated with secondary plots from the same target. Secondary radar signals are decoded at this stage.

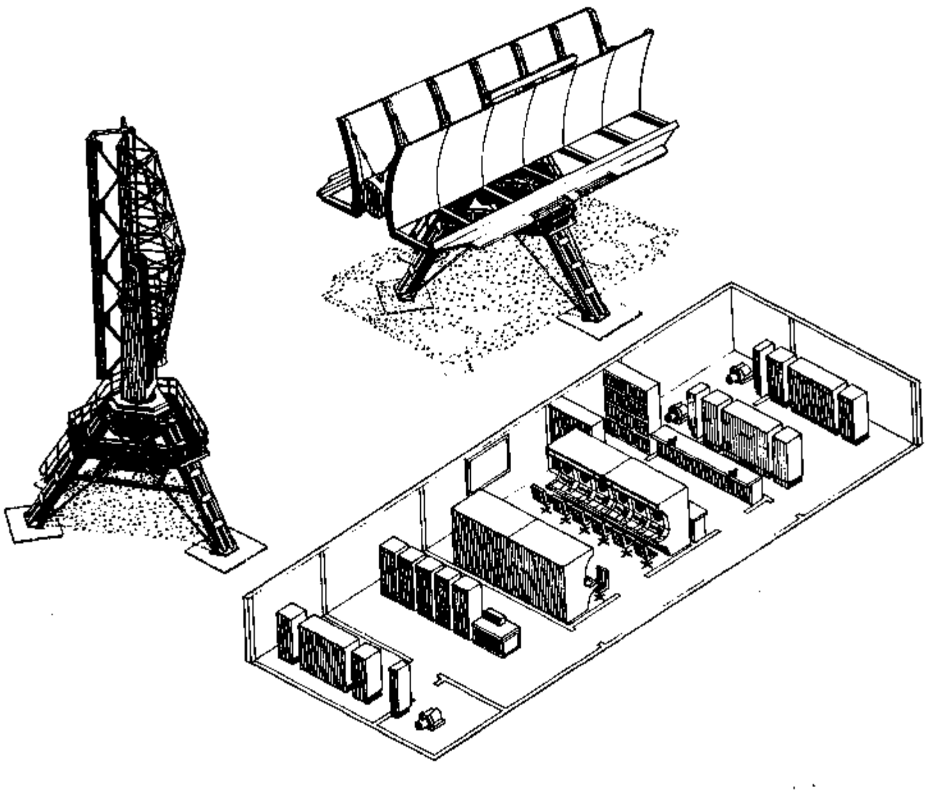
The heightfinder radars respond to demands from the display and data processing system and the signals received from the selected targets are analysed in the automatic plot extraction equipment and the height values computed.

As control signals to the radar aerial equipment and the data therefrom can be expressed in a form suitable for transmission over narrow bandwidth data links, it is possible to locate the aerials for optimum radar cover at sites remote from the display and data processing systems.

Air Defence Operation Centre (ADOC)

Up-to-date information on the deployment of forces, availability of resources and the extent of engagement is an essential ingredient of an efficient operational centre. The following description assumes the provision of data processing and display equipment from the Marconi range.

In an air defence operations centre, a Myriad computer, with specialised peripheral equipment, accepts data entering from a number of remote control centres via narrow band digital data links. The data link messages are reassembled and checked for parity errors as the information is collected together in the data store. Where messages are received from a number of remote stations, co-ordinate conversion is carried out to allow the positional information to be referred to a common reference for presentation purposes. A large-screen projector or rapid processing photographic machine provides conference facilities. In addition, individual user's displays from the S3000 range provide information in both graphical and tabular form allowing the higher command staff to call down further information on any aspect of the defence situation. Extension of the system is possible to embrace such matters as availability of transport, logistics data on maintenance, reserves and effects of force re-configuration. Gathering of data and exercising the system under practice conditions is an important feature and these systems may be programmed for simulation studies to establish effective co-ordination of the entire defence organisation.



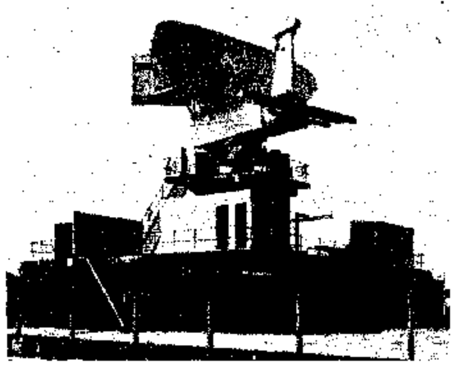
Arrangement of a static area control station

Display and data processing system

Utilisation of the radar data occurs in the underground operations centre where a computerised display and data handling system speeds the transfer of data, filters out extraneous signals, calculates the threat and advises the operating personnel on the best defensive measures. The extent of the equipment in the centre is determined by the assessment of the threat in terms of tracks to be handled and the extent of the defensive structure in terms of hostile engagements.

The computer complex is based on the Myriad III. Display requirements are met by adopting a modular approach; six displays (three plan-position indicators and three tabulars) are served by a local processor which acts as a display controller. In this way, the display refresh rate is kept at 25 Hz to avoid flicker. Up-dating of tracker ball control information, display format control, category selection and interpretation of light-pen data entries are also carried out with minimum load on the central processor.

The displays themselves employ digital techniques throughout to improve stability and minimise setting-up procedures. All display positions use identical equipment, their operational role being determined by the computer programme, which selects the relevant portion of its adaptive routine to meet the desired role. Operational organisations may be altered with minimum disturbance when new facilities are required.



40-series volumetric radar for static air defence systems

The total display content for a particular system is provided by assembling the appropriate quota of display modules. For example, a display system having eighteen operational displays is met by use of six modules. This design philosophy ensures that malfunction in a module affects a limited part of the system and realises a high level of operational reliability.

The computer complex automatically services digital data links feeding data to adjacent sector operations centres, surface-to-air missile sites and air defence headquarters. Similarly, incoming data is accepted from digital data links, checked for transmission errors and entered into the display read-out routines where required.

Without the restrictions imposed by considerations of transportability, the system can be extended to meet virtually any level in capacity, but the operational facilities available are generally as for the S600 Series transportable Area Control Stations. The computer programmes incorporate the same software packages, so that operational procedures can be similar throughout defence organisations where static and mobile installations co-exist.

MANUFACTURER:

Marconi Radar Systems Ltd, Chelmsford, England.

2421.181
NOMAD

DESCRIPTION:

NOMAD is a fully air-portable data handling system designed to operate in conjunction with either 3D radars or 2D plan radars supported by heightfinding radars which, with ground-to-air plus ground to ground communications facilities and secondary radar, provide a complete tactical air control system.

On site, the equipment comprises two main sections – the operations centre, which contains displays and display drive and back-up equipment, and the computer complex. Both sections are housed in inflatable shelters.

Digital computing is used to process the input data from primary radars thus permitting the semi-automatic tracking of targets. Simultaneous control of multiple fighter interceptions and surface-to-air missile engagements is possible, the SAM launch control post being fully integrated into the system by digital data links.

OPERATION:

The operational organisation of the Nomad system can be divided into groups under the Air Defence Commander, who is in overall command:

Executive group – comprising the Chief Fighter Controller, the Chief SAM Controller, and various liaison executives, for other services.

Operational group – comprising Fighter Controllers, SAM Controllers, trackers and heightfinder operators.

The system provides semi-automatic tracking of targets, with track storage, and simultaneous control of a number of fighter interceptions and surface-to-air missile engagements. Identification of aircraft is assisted by the use of secondary radar (IFF).

Fighter interceptions are dependent on the characteristics of a particular aircraft, such as its performance in climb, cruise, acceleration, turn, etc. The characteristics of up to four fighter types can be held in the computer as stored data. The Nomad system can accommodate new or revised types of fighter characteristics by means of a small programme change. To effect an interception, the fighter controller must supply the computer with the following data via his keyboard:

Target track number
Fighter/weapon combination.
Fighter bases available.

The computer will calculate an interception profile for the selected fighter from this data together with the stored fighter performance data and will indicate to the controller on his tabular display:

if an interception is possible;
predicted kill point;
recovery probability;
command instructions to direct the fighter on the optimum flight path.

The tabular display will also indicate

Fighter/weapon choice;
Selected fighter/weapon base.

Should the interception be shown to be impossible or recovery to be marginal the fighter controller may immediately select a different fighter/weapon combination or fighter base and read the information on the re-calculated situation. Throughout the interception a continuous calculation is made of the amount of fuel which the fighter will retain for recovery to a given airfield after the interception.

When effecting surface-to-air missile engagements, the SAM controller is presented with a threat priority list of SAM targets. He decides from this in which order to engage the targets: the range, bearing, elevation and range-rate of the target is automatically fed to the selected SAM site via the digital data link for use by the target illumination radar (TIR) in locking on to the target. After lock-on is achieved, a check reply is sent back to the SAM controller who may then, after verification of target identity, order the firing of the missile salvo.

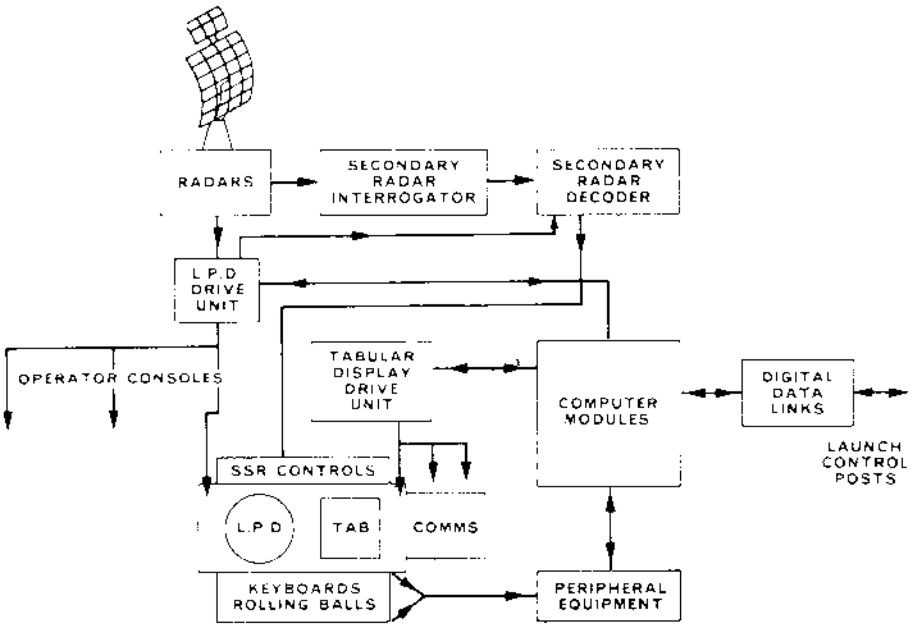
The display equipment used by all controller/tracker pairs is identical, being built on a modular basis. This provides a continued though reduced operational capability in the event of a technical failure, since a chief controller can take over a controller tracker position with a loss to the system of the capacity of the position taken over. The controller/tracker pairs use dual consoles comprising:

Plessey TDS Mk 5 Labelled Plan display (LPD)
Plessey TDS Mk 7 Tabular display
Rolling ball symbol position control.
Two keyboards (general purpose) for insertion of alpha-numeric data to computer, and call-down of data from the computer.
Plessey 'Minicom' Communications Controls.
Secondary radar controls.

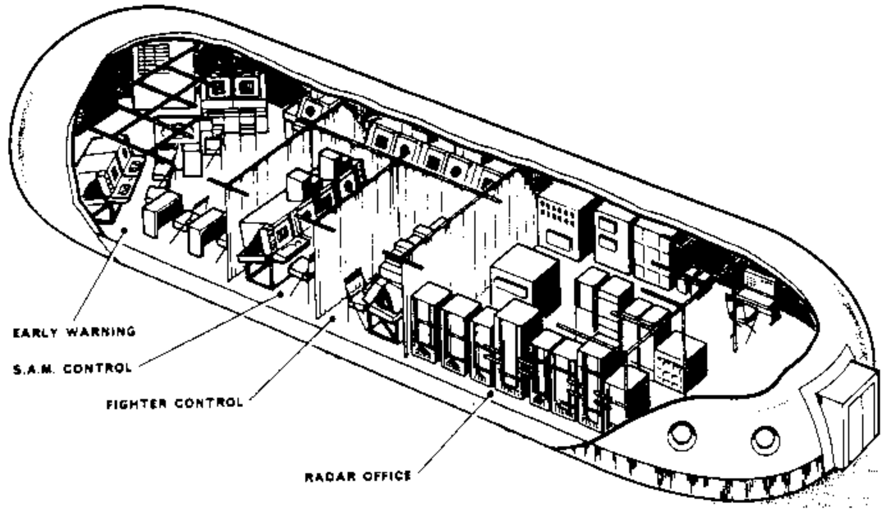
The air defence commander shares a display with the display controller and the control executive. This is a 53 cm conference labelled plan display, complete with rolling ball controls, keyboards, communications control and secondary radar controls.

SEMI AUTOMATIC TRACKING:

In a semi-automatic tracking system the operator participates in the track generation process to the extent that is necessary to select targets for tracking and to ensure that targets are not lost or confused; while the computer functions to reduce the operator's workload and produce a smooth track. Tracking is initiated by an LPD operator by marking with a moving electrical marker and setting the computer to work on this input data. The computer generates a track from this input and predicts the target's future position: its prediction is in turn connected by the operator whereupon the computer makes a further prediction, and so on. Height information – whether derived from 3D radar or a separate heightfinder – is also supplied to the computer to aid it in its track pre-

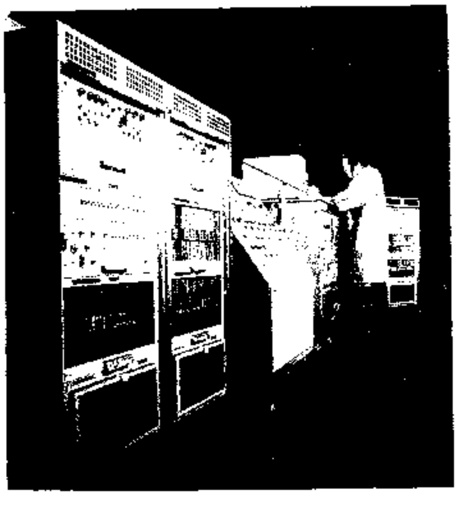


Schematic showing part of the Nomad system and its relationship with primary and secondary radars and SAM launch control posts



OPERATIONS ROOM SHELTER

Typical layout of Nomad operation room shelter



Marconi-Elliott computer equipment for Nomad in production diction. This technique makes it possible for one operator to track several targets simultaneously if required.

DEVELOPMENT HISTORY:

The command of air battles at continually changing forward locations presents a difficult task when using orthodox fixed-site control and reporting units. Flexible and effective control can only be obtained when using readily transportable and highly reliable control centres which can be deployed and made operational in a short space of time. The British Government required a number of such units and in 1965 awarded a contract to Plessey Radar to work with Elliott-Automation (now Marconi-Elliott Avionic Systems Ltd) in the design and manufacture of a number of systems. From this joint effort came the idea of developing a further system for commercial sale, and Nomad was the result.

The system has been specified as the central data processing and control complex of the British Aircraft Corporation's Thunderbird 22 system (**2461.131**) which they are offering for commercial sale.

MAJOR SYSTEM ELEMENTS AND SUPPLIERS:

i A digital computer system, with built-in redundancy, permitting further expansion, using Marconi-Elliott 920B computers, together with display/computer interface equipment.

ii Plessey TDS Mk 5 Labelled Plan radar displays.

iii Plessey TDS Mk 5 Height Finder radar displays.

iv Plessey TDS Mk 7 Tabular displays.

v Plessey Display Drive Distribution and Character Generation equipment.

vi Secondary Radar Decoding equipment produced by Elliott-Automation.

vii Solartron high resolution Video Map generators.

viii Plessey 'Minicom' Communications Control equipment.

MANUFACTURER:

Plessey Radar Ltd, Addlestone, Surrey, England.

2461.181
THUNDERBIRD 22

DESCRIPTION:

Thunderbird 22 is the name given by the British Aircraft Corporation to the comprehensive Air Defence System which includes basic Thunderbird 2 firing units.

Facilities provided by the complete system include detection and identification of friendly or hostile aircraft, threat evaluation, engagement of medium-level and high-level attacks by Thunderbird batteries and GCI control of fighter aircraft. The units of the system are linked by a comprehensive command communications network.

Operational centre of the system is the Nomad Missile and Fighter Control centre. This is a complex data-processing and data-display arrangement built round a high-capacity digital computer. Data inputs to the system come from a Tactical Control/Early Warning Radar and a Height-Finding Radar and from an associated secondary radar (IFF) interrogator responsor and decoder. This information is presented on displays that permit the semi-automatic tracking of targets; the resultant tracks for hostile targets are stored by the computer and processed to provide advisory information to enable the Air Defence Commander to decide how to meet the threat. In presenting this information the computer draws on other stored (and periodically updated) data such as weapon availability and state of readiness for interceptor performance and availability. When the engagement decision is taken, control of the engagement is assumed either by the surface-to-air Missile Control Centre or by the Fighter Control Centre as appropriate. Both centres are located in the Nomad complex and are served by the same radar and computer system; but in other respects their functions and procedures are similar to those of independent GCI or missile control centres – e.g. the Battery Command Post of Thunderbird 2 – except insofar as procedures prior to the engagement decision are concerned.

SYSTEM COMPONENTS:

Major components of the system (excluding aircraft) are listed below, together with the names of the manufacturers principally concerned with them. More detailed information can be found in the entries for the system components.

COMPLETE SYSTEM	British Aircraft Corporation Ltd.
MOBILE TACTICAL CONTROL AND EARLY WARNING RADAR	Marconi Radar Systems Ltd
MOBILE HEIGHT-FINDING RADAR	Marconi Radar Systems Ltd.
NOMAD MISSILE AND FIGHTER CONTROL CENTRE	Plessey Radar Ltd. Marconi Radar Systems Ltd. Marconi-Elliott Computer Systems Ltd.
THUNDERBIRD 2 SAM BATTERIES	British Aircraft Corporation Ltd. Ferranti Ltd.
RAPIER SAM BATTERIES	British Aircraft Corporation Ltd.
COMMAND COMMUNICATIONS SYSTEM	Marconi Radar Systems Ltd.

Launch of Thunderbird missile

2444.181
UK AIR DEFENCE SYSTEM

DESCRIPTION:

It was decided in 1972 that British air defence policy, which for some time had been based on a "trip-wire" concept of reaction to an air-launched nuclear attack coupled with anti-reconnaissance operations conducted by a small interceptor force, would be changed to include provision for defence against conventional attack. The implications of this policy change are summarised below.

Radar Coverage. Existing radar coverage was primarily to the North and East and primarily provided by three major radar stations. Coverage in other directions was provided to a lower standard by smaller military radars and, to some extent, by civil/military ATC surveillance radars.

To provide defence against conventional attack, which may come from any quarter, greater use of existing civil radars would have to be made. In addition a new military radar station was to be established on Benbecula in the Scottish Western Isles. Further coverage could be provided by airborne early warning radar (AEW), initially by converted Shackleton maritime patrol aircraft and subsequently by an AEW conversion of the Shackleton's successor Nimrod, for which a British AEW radar was to be developed.

Systems Survival. Once a conventional attack was contemplated the centralised Linesman (**2243.181**) control system was evidently excessively vulnerable. Instead, a "ring main" type of decentralised control would be used, for which techniques had been developed by the RAF. These techniques included the use of in-flight refuelling which, with adequate AEW cover, enabled interceptions to be made at distances up to 1,250 km from the coast.

Interceptors. Manned interceptor strength would be increased by retaining the existing Lightning aircraft in service instead of retiring them when the new Jaguars become operational. A significant number of the new MRCA, also, would be purchased for use in the air superiority role. What steps would be taken to provide improved surface-to-air missile coverage was less clear; but evidently the British Army's Rapier systems would be able to make a contribution and it was known that the British Government had been contemplating authorising the development of a medium-to-high altitude anti-aircraft missile.

The rearrangements described or implicit in this change of policy are not yet complete, but the description which follows is believed to be reasonably representative of the present situation.

The United Kingdom Air Defence Region is part of NATINA (NATO Integrated Air Defence) and the UK air defence system is coupled into the continental air defence systems by its links with six NADGE stations (**1181.181**). The UK data terminal for these links is the West Drayton complex which was originally intended as the heart of Linesman. Incoming data is relayed from West Drayton to the Air Defence Operations Centre (ADOC) at High Wycombe and thence to the Sector Operations Centres (SOC) at Buchan, Bulmer and Neatishead. These SOCs and the ADOC form the "ring main" described above.

Each SOC consists of a radar system and a control and reporting centre. The main types of radar used in the all-military elements of the system are the pre-Linesman Plessey (formerly Decca) Type 80 200 nm 2D L-band surveillance radar, the Linesman Types 84 and 85 (3D, entry **2457.153**) and the two mobile and transportable radars developed originally for the Thunderbird system (**2460.131**) the Type 88 S/L-band surveillance radar and the Type 89 C-band heightfinder (**2463.153**). Heightfinding facilities for the Types 80 and 84 surveillance radars are provided by Plessey HF200 height-finders (**1142.153**).

Inherited from the Linesman scheme is the possibility of requisitioning surveillance facilities from civil ATC radars such as the Plessey AR-5D installations (**2416.153**) at Burrington, N. Devon, and Clee Hill in Shropshire. Further back-up or early warning radar data is supplied to the system by Shackleton AEW aircraft carrying APS-20F radar.

THE UNITED STATES OF AMERICA

2533.181
AIR WEAPONS CONTROL SYSTEM 412L

DESCRIPTION:

Air Weapons Control System 412L is a very substantial defence complex which automatically performs the functions of air space surveillance, identification, and weapons control for air defence, strike, and reconnaissance missions with only nominal manual assistance. It is located in West Germany.

AWCS 412L integrates sensors, communications, processors, displays, and operators into a total air weapons control and management system. Many existing sensors and radio sets from the inventory were incorporated into the system, and additional automatic detection equipment processors, displays, switching centres, and peripherals were developed as necessary to provide the total system capability and integration required.

The system performs the functions of data acquisition, data processing and display, and communications in an operational environment which includes Reporting Posts, Control and Reporting Posts, Control and Reporting Centres, and a Combat Operations Centre. The Data Acquisition Subsystem, which serves as the sensor head for the system, is made up largely of existing radar and IFF equipment. General Electric developed a Radar Signal Processor Group for this subsystem that combines, processes, and distributes target video information, timing references, and gating signals. Data from this group is transferred to the Data Processing and Display Subsystem by equipment of the Communications Subsystem. The Data Processing and Display Subsystem provides automatic detection, tracking, storage, and display functions for data obtained from the Data Acquisition Subsystem, for cross-told data from other sites, and for manually inserted data. In addition this subsystem processes, correlates, and displays overall weapon and weather status information within the surveillance area. The collection, dissemination, and display of track data by AWCS 412L results in a threat evaluation. If an intercept is ordered or a surface-to-air missile (SAM) launch is commanded, AWCS 412L computes and transmits the necessary intercept data.

The Reporting Post is the lowest element in the AWCS 412L operational hierarchy. It provides the functions of automatic detection and tracking of targets within its designated surveillance area, passing the track data on to its parent Control and Reporting Post.

The Control and Reporting Post also acquires and tracks targets, and it has the additional function of target identification for its own tracks and those of subordinate RP's. This information is passed to the next higher echelon, the Control and Reporting Centre (CRC), and the CRP also has delegated weapons control facilities for its specific area of responsibility.

The CRC possesses all the capabilities of the CRP, including its own radars, but it has additional capabilities and facilities for surveillance, identification, situation display, weapons assignment and control, and jammer tracking.

The highest level of the AWCS 412L operational hierarchy is the Combat Operations Centre. Overall command of the air situation is exercised from this centre. Information inputs include processed data from the RP's, CRP's and CRC's, intelligence data, weapon status information, force deployment, and readiness data. AWCS 412L provides for the collection, processing, and display of this information and for communication to lateral or higher echelons and to other elements of the system.

DEVELOPMENT:

In providing the Systems Management and Integration Engineering Services for AWCS 412L, the General Electric Company integrated the equipment and services provided by other prime equipment contractors and provided interface equipment to ensure a compatible operational system. As an additional element of these services, the test programme to validate the system's operational capability was also formulated and implemented.

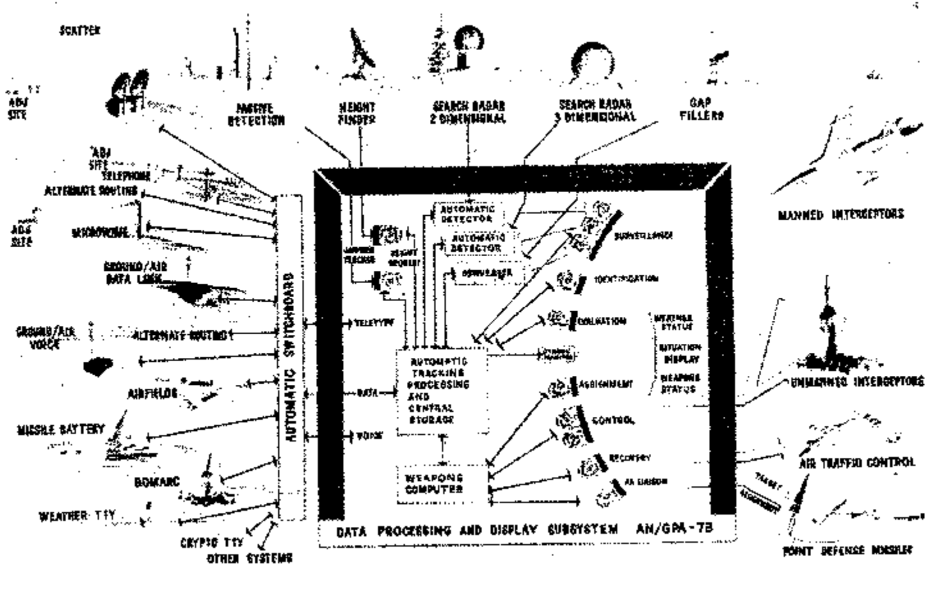
In its role as prime equipment contractor for the Data Processing and Display Subsystem of AWCS 412L, the General Electric Company designed, manufactured, and tested the AN/GPA-73 Radar Course Directing Group. This equipment provided real-time automatic detection, tracking, storage, correlation, data transfer, interrogation, evolution, control calculation, and display functions.

STATUS:

AWCS 412L is located in the Federal Republic of Germany and consists of seven sites digitally netted together to perform the functions of surveillance, identification, evaluation, weapon assignment, and weapon control. It is currently being used by NATO, the German Air Force, and the United States Air Force.

MANUFACTURER:

System Contractor: General Electric Company, Heavy Military Electronics Systems, Syracuse, New York, USA.



Air Weapons Control System 412L

Air Weapons Control System 412L Operations Room

2525.181
BALLISTIC MISSILE EARLY WARNING SYSTEM (BMEWS)

DESCRIPTION:

The BMEWS system comprises a small chain of very large radars for the detection of a ballistic missile attack on North America from the general direction of Russia. There are three operational sites – Site I in Thule, Greenland, Site II in Clear, Alaska, and Site III on Fylingdales Moor in England.

Three types of radar are used. At Sites I and II there are AN/FPS-50 radars (**2511.153**); these are described in Section 3 but it may briefly be noted here that they use large static arrays that are scanned by an organ-pipe scanner. At Sites I and III there are AN/FPS-49 radars (**2509.153**) which are large tracking radars with parabolic reflectors. At Site II there is an AN/FPS-92 which is similar to the FPS-49 but is a more modern version.

Information on BMEWS targets is transferred by a communications network to the North American Air Defence (NORAD) Combat Operations Centre.

STATUS:

Operational and likely to remain so although the suggestion has been made recently that when the early warning satellite network becomes fully operational – probably before the mid-1970s – the sites at Thule and Clear may be shut down. The

BMEWS Site III in England

development of satellite interception techniques, however, seems to make it unlikely that the US authorities would lightly dispense with the back-up warning system that BMEWS can provide – at least so far as trans-Arctic missiles are concerned.

Additional information on ground-launched ballistic missiles will be provided by the new forward-scatter, and forthcoming back-scatter, Over-the-Horizon (OTH) radars (**2750.181**) which will also probably supersede – at least in part – the DEW radars (**2567.181**). Information on submarine-launched missiles is already available from the now-operational System 474N radars (**2810.181**). The BMEWS system number is 474L.

MANUFACTURERS:

Main contractors for the BMEWS radar systems were RCA, General Electric and Western Electric.

2567.181
DISTANT EARLY WARNING SYSTEM (DEW LINE)

DESCRIPTION:

One of the earlier parts of the complex of radar systems designed to warn the US military authorities of the approach of enemy aircraft or missiles, the DEW Line, is an array of radars that stretches across the northern areas of North America from Alaska to Greenland.

Main radars of the line are the AN/FPS-19 and AN/FPS-30. The number of radars in the DEW Line has been reduced in recent years and is now 31. Information from these radars is conveyed by way of a communications network to the North American Air Defence (NORAD) Combat Operations Centre, together with data from the other warning networks described in this section.

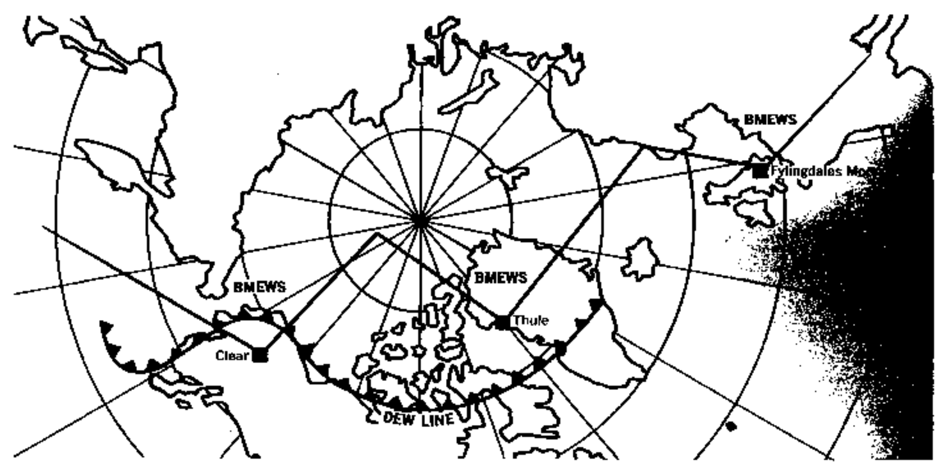
STATUS:

Operational, but likely to be progressively replaced operationally by more modern systems (see, however, **2750.181** below).

The system reference number of the chain is 413L.

MANUFACTURERS:

Many manufacturers were involved in the supply of equipment for and the construction of the radar chain. Prime system contractor was Western Electric. Radar main contractors were Raytheon, Budd and Sperry.



Deployment of Ballistic Missile Early Warning System (BMEWS) and the Distant Early Warning (DEW) Line

2750.181
OVER-THE-HORIZON (OTH) RADAR SYSTEMS

DESCRIPTION:

There are currently two programmes under the control of USAF Systems Command for the provision of extremely long-range radar data for air defence purposes. The more advanced of the two is system 440L for which hardware exists and which is a forward-scatter system: the other is a backscatter system.

Hardware development for the backscatter system has been proceeding. RCA have constructed an AN/FPS-95 OTH radar for the USAF for the purpose of gaining experience with backscatter HF systems. The FPS-95 uses a giant log-periodic antenna whose elements are several hundreds of metres long. Other experimental equipment has been produced by the ITT group (see below).

One of the problems to be explored has been the effect of ionisation in the auroral belt on backscatter systems. This is unimportant for the eastward and westward-looking OTH backscatter systems that are planned as the Conus-OTH-B system, but it is vitally important for the northward-looking NORAD-OTH-A system. However, preliminary investigations up to mid-1971 gave encouraging results and further experiments (see below) were put in hand.

The forward-scatter system is associated with BMEWS (**2525.181**) and is concerned with the detection of ballistic missile attack, including particularly attacks from directions other than over the North Pole and depressed trajectory and FOBS attack. The backscatter system is intended largely for the detection of airborne attack and is expected to replace most of the current DEW/SAGE/BUIC operations.

In May, 1972, it was announced that the US and Canadian defence departments would conduct a joint evaluation of OTH radar in the auroral belt of the Canadian Arctic, starting mid-1972.

Basis of the evaluation programme was the installation of a radar transmitter and two receivers, and the experiments and investigations are to cover both the operational performance of the equipment so far developed and the technical and logistical problems of installing and operating radars of the sort in these Arctic regions and particularly, of course, the auroral problem.

Starting in June, 1972, the USAF set about installing a transmitter and receiver at Hall Beach on the Melville Peninsula north of the Arctic Circle. The project name for this operation was Polar Cap III. At the same time a second receiver was installed by the Canadian Defence Research Board at Cambridge Bay on Victoria Island, some 900 km westwards from Hall Beach. The two receivers were closer to Thule than to Clear; nevertheless their coverage to some extent complemented that of BMEWS (**2525.181**) and it has been observed that the Hall Beach radar is ideally located for the observation of trans-Polar flights.

The purpose of the second, Canadian, receiver was said to be that of enhancing the probability of target detection by giving data from two directions instead of one. The Cambridge Bay receiver is also substantially closer to the North Magnetic Pole than is the equipment at Hall Beach. Experiments were expected to start in October 1972 and to continue until August 1973, and it was proposed that a number of remotely controlled beacons be set up at sites in high Arctic latitudes to simulate targets for the radar tests.

Total cost of the project is unknown but the Hall Beach operation was reported to be costing $8 million. Prime contractor for the Polar Cap III radar is the ITT subsidiary, Electronic Physics Laboratory.

STATUS:
In his annual report for FY 1975 the US Defence Secretary said that the US authorities propose to continue development of OTH-B ($12 million in the FY 1975 budget) and that three such radars would give adequate early warning of bomber attacks from all directions except the north. Mr Schlesinger went on to say that for the northern approach "we will have to retain the 31 DEW line radars until such time as we can perfect an OTH radar, or some other system, which can operate successfully in the presence of the intense electrical disturbances which characterise the northern auroral zone". From this it is evident that the northward-looking experiment was less successful than their preliminary investigations had led the scientists to expect.

2801.181
SAFOC SEMI-AUTOMATED FLIGHT OPERATIONS CENTRE

DESCRIPTION:
This is an automatic system which is being built by the Hughes Aircraft Company under a US Army contract. Its purpose is the automatic monitoring of the positions of all aircraft under its control.
Manual regulation of military air traffic is not only time-consuming, it is also subject to human error. The new system will provide a collision-avoidance capability, pin-point the location of distressed or downed aircraft, identify friendly aircraft, provide ground-to-ground co-ordination of aircraft movement, and disseminate air-warning information to pilots.
MANUFACTURER:
Hughes Aircraft Company, Fullerton, California.

2803.181
SAGE (SEMI-AUTOMATIC GROUND ENVIRONMENT) AIR DEFENCE SYSTEM

DESCRIPTION:
Developed and installed throughout the USA and in part of Canada during the 1950s, the SAGE system is the longest established element of the North American air defences. It is still operational but – at least so far as the main bulk of the system is concerned – it must now be regarded as obsolescent.
The design of the SAGE system was initiated by the Lincoln Laboratories of the Massachusetts Institute of Technology in conjunction with the Air Defence Command of the USAF. The underlying concept of the system is centralised data processing: the system receives surveillance data from a network of radars and controls air defence weapons over areas substantially greater than the coverage of a single long-range search radar. System inputs, however, go far beyond the simple provision of target data from two-dimensional surveillance radars. They include data from heightfinding radars and from airborne and shipborne early warning systems, meteorological data, weapon status information and flight plan data for military and civilian aircraft movements within the area of interest.
The organisation of SAGE and associated systems has been extensively revised in recent years. Currently the Continental United States and part of Canada is divided into six Air Defence Regions, each of which has one Region Control Centre. In addition there is one Air Defence Region in Canada and one in Alaska – the Canadian region also having a Region Control Centre backed up by a BUIC-III (Back-up Interceptor Control) centre plus a manual control centre in Labrador. The Alaskan region has a manual Regional Control Centre.
All SAGE Region Control Centres are tied directly into the North American Air Defence (NORAD) Combat Operation Centre and will range the air battle in the region as well as conducting the actual intercepts.
STATUS:
The programme number of the basic SAGE system is 416L. BUIC system number is 416M. Some other relevant programmes are SEED CLEAR for updating the AN/FPS-27 SAGE radars (which in turn replaced the FPS-10 radars phased out in 1963); system programme 416Q (Common Digitiser) – a data processing system to be employed at USAF, Canadian and USAF/FAA joint-radar sites to replace the AN/FST-2 data transmission system and provide primary and secondary radar data to SAGE/BUIC and FAA National Airspace Systems; system programme 425L for the NORAD Combat Operations Centre, improvements to which are still being made; system programme 427M for the NORAD Cheyenne Mountain Complex (CMC) to provide adequate capability up to 1980; and system programme 433L for the provision of meteorological data.
MANUFACTURERS:
The list of manufacturers for the whole SAGE/BUIC system is obviously very long. Principal contractors for 416L, however, were Western Electric, SDC and Burroughs. Radars for SAGE were provided by General Electric (FPS-7, FPS-24) Bendix (FPS-20, FPS-64, FPS-65, FPS-66, FPS-67) Avco (FPS-26) Westinghouse (FPS-27) Raytheon (FPS-28) and Sperry (FPS-35).

2810.181
SLBM DETECTION SYSTEM – SYSTEM 474N
DESCRIPTION:
This system, which became operational in 1971, is designed to detect missiles launched by submarines operating either in the Atlantic or in the Pacific Ocean. It consists of seven radars located three on each coast of the USA and one in Texas. The main radar used is the AN/FSS-7 (**2538.153**), which is made by Avco; in 1972, however, it was decided to supplement these radars with about 20 per cent of the surveillance capacity of the AN/FPS-85 radar (**2546.153**) which is otherwise assigned to the SPACETRACK programme (**2825.181**) and which can provide coverage over most of Central America and the Caribbean.
STATUS:
Operational with the AN/FSS-7 since 1971. Scheduled to be operational with the AN/FPS-85 by mid-1974.

2825.181
SPACETRACK
DESCRIPTION:
Spacetrack is the system code-name for System 496L, the USAF worldwide system for the detection, tracking and identification of all objects in space. It is composed of large radar optical and radio-metric sensors located around the globe and its control centre maintains a catalogue of all objects in space.
Main sensors of the system are the AN/FPS-85 radar (**2546.153**) and the AN/FSR-2 passive optical sensor. The FPS-85, of which the FPS-46 was the prototype, is an electronically steerable array radar (ESAR) operating in the UHF band and giving three-dimensional information on all satellites and similar objects passing over it. FSR-2 is a passive optical surveillance system.
SPACETRACK data forms part of the input to SPADATS – the NORAD space object detection system.
STATUS:
Operational.
MANUFACTURERS:
Numerous. Some of the principal ones have been Bendix, Cutler-Hammer, General Electric, Philco-Ford, RCA, SDC.

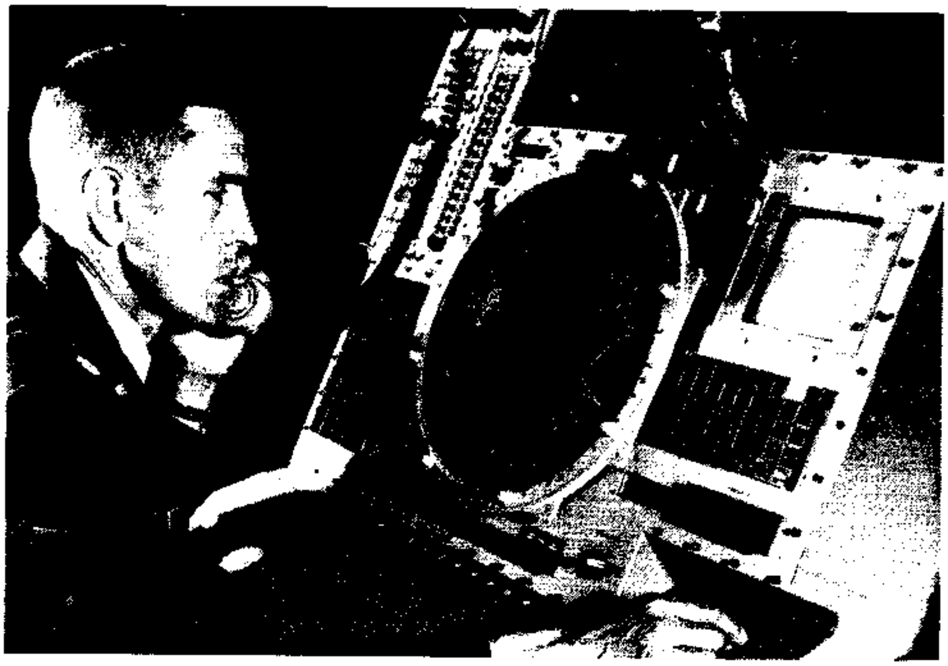
2824.181
TACTICAL AIR CONTROL SYSTEM – TACS
DESCRIPTION:
Designated as System 407L, TACS is a highly mobile communications and electronics system for command and control of tactical air operations. It is a modular system that can be deployed by transport aircraft, helicopters or land vehicles and can be adapted to suit particular military or environmental conditions.
The system will provide radar and communications facilities both for the support of land forces and for military air traffic control. Units of the system include radars, computers, displays and communications equipment.
Typical of the equipment being supplied for the system is the AN/TPS-44 radar (**2518.153**) which forms part of the Forward Air Control Post (FACP). Each of these radars comprises three main packages – an equipment shelter, a power pallet, and an antenna pallet. All three are easily transportable by truck, helicopter sling-lift, cargo aircraft, or wheeled transporters.
The equipment shelter houses radar display scopes, transmitter, receiver, and other electronic equipment. All electronic units are rack-mounted on slides so that they can be pulled out and tilted for convenient servicing. Extensive use of plug-in modules, monitoring of power circuits, and numerous accessible test points provide a high-degree of maintainability. A self-contained air conditioner and heater unit allows efficient operation of the equipment in both arctic and tropical climates.
The power pallet consists of two gas-turbine generator sets and connecting power cables. The third pallet contains the antenna-pedestal, collapsable tower support stand, and stabilisation outriggers.
The antenna reflector incorporates two removable wing tip sections, two hinged inner wing sections, and a centre section. Both the antenna reflector and feedhorn are mounted on a pedestal. Four separate stabilising jacks on the antenna pallet provide a firm platform for the pedestal without the use of guy wires or ground stakes even in winds up to fifty-two knots. The pedestal has a built-in levelling system to ensure proper alignment of the antenna.
A feature of the system that aids mobility and shortens time into action of the system is the use of inflatable shelters of a size great enough to accommodate a wide range of display and data processing equipment such as is required for sophisticated tactical air control operations.
Apart from the TPS-44 radar, with which are associated sophisticated lightweight display units, other major sub-systems of TACS are:

AN/MRC-107	Mobile communications centre for forward ATC
AN/TCC-30	Electronic switching centre
AN/TPN-19	Air transportable ground landing control

AN/TRC-97A	Air transportable tropospheric scatter communications terminal
AN/TSC-53	Transportable FACP communications centre.
AN/TSQ-47	(FOUR WHEELS) Air transportable ATC/communications system
AN/TSQ-61	Transportable FACP communications centre
AN/TSW-7	Transportable UHF/VHF ATC tower
AN/TVN-1	Air transportable airfield lighting system

STATUS:
Procurement and implementation. A follow-up system (485L) TACSI – TACS Improvements – is largely at the R & D stage.

MANUFACTURERS:
General Systems analysis and management is by the Mitre Corporation. TPS-44 radars are by Cardion Electronic, communications by RCA and General Dynamics, landing control equipment by LFE and Raytheon, display equipment and inflatable shelters by Hughes. This list is not, of course, exhaustive.



TACS display console by Hughes. These light-weight multi-purpose consoles can display both raw radar data and computer generated material for surveillance tracking and ATC

2835.181
TSQ-73 AIR DEFENCE SYSTEM
DESCRIPTION:
AN/TSQ-73 is an air defence missile control system that is being developed by Litton Industries to meet a US Army requirement. It is expected, however, that it will also be supplied to the land forces of other countries.

The AN/TSQ-73 will be deployed world-wide with army air defence units. The system performs area radar surveillance and co-ordinates the action of a number of Hawk and Nike missile batteries against enemy aircraft. The system is highly automated to permit rapid reaction to destroy enemy aircraft before they reach tactical positions.

Designed for tactical operations in any climate, the system is housed in small shelters which can be quickly moved by aircraft, helicopter or truck. Much of the equipment is also used by the US Army's TACFIRE artillery control system (**2827.163**) so that there will be considerable savings in testing, support and training, in addition to the lower procurement costs.

The system consists of high-speed digital computers, advanced tactical display consoles and digital communications terminal equipment.
STATUS:
Development (on a $8.5 million contract).
MANUFACTURER:
Litton Industries, Data Systems Division.

THE UNION OF SOVIET SOCIALIST REPUBLICS

2899.181
AIR DEFENCE SYSTEMS – GENERAL
The total air defence capability of the USSR is enormous – far in excess of that of any other country. Detailed information on the Russian air defence systems is in short supply – even more so than information on the missiles, guns and radars that go to make up these systems: it has been estimated, however, that the USSR has around 10,000 surface-to-air missile launchers and thousands of air defence radars to go with them. The entries that follow provide a little information on some specific systems.

The development and deployment of Russian ABM systems is of course vitally affected by the US-USSR ABM agreements. Exactly how the Russians will interpret these is of course unknown at present; but certainly with their existing scale of radar and missile development and deployment it seems unlikely that they will suffer hardship as a result of the treaty.

2945.181
MOSCOW AIR DEFENCES

Reports – mainly from US sources – indicate that there are two air defence systems deployed in the Moscow area. One of these, strictly an anti-aircraft system, is based on the Guild (**2944.131**) surface-to-air missile, also known by the US code SA-1; and it would appear to be more appropriate to a system of defence against mass bombing raids, such as those employed in the Second World War, than to modern low-level attacks for which the Goa (**2938.131**) missile is the best known to be available in the Soviet Union.

The other defence system is an anti-ballistic missile system based on the Galosh (**2932.131**) ABM missile. Unlike the US Safeguard (**2798.131**) system with its long-range and short-range missiles, the Moscow ABM system appears to be intended for use with only one kind of ABM missile but possibly with more than one variant of this missile. Associated with this missile are early warning acquisition and tracking radars. The early warning radar is an enormous equipment with an aerial measuring about 275 metres by 30 metres and apparently performs both warning and acquisition functions: it has been christened Hen House (**2879.153**) by the US authorities. A typical detection range for one of these radars is believed to be 6,000 km. Additional acquisition functions are apparently performed by a smaller, but still enormous, radar known as Dog House (**2864.153**). Finally it appears that target tracking and missile guidance are performed by large dome-covered tracking radars, known as Try-Adds, which are located at the four sites round Moscow. The Try-Add radars are believed to be relatively short-range high-precision devices, but the Dog House radars are credited with a range capability in the region of 3,000 km.

2989.181
TALLINN AIR DEFENCE SYSTEM

Information on the Tallinn air defence system has to be treated with some reserve. It is reported that the system is designed for use both against aircraft and against missiles, and that it is based on the missile known to the US authorities as the SA-5 of which it is said that there are about 1,000 in the system. This missile is sometimes referred to by the NATO code-name Griffon (**2940.131**) but it has also been identified with one called Gammon. It has also been said that Griffon, as a project, is thought to have been abandoned.

Setting aside the question of which missile is which, however, it does appear, from persistent US reports, that a large surface-to-air missile is deployed in quantity in the Tallinn area. The view generally taken is that this defence system, while clearly suitable for the interception of high-speed high-altitude aircraft, is so little better for this purpose than comparable systems employing the SA-2 Guideline missile (**2942.131**) that it is probably intended also to be an ABM system. If the missile used is indeed the one that is commonly identified as Griffon it certainly seems possible that this might have an interception capability not so different from that of Spartan (**2811.131**), as to rule out the ABM possibility altogether; and this possibility is reinforced by the suggestion that the giant Hen House/Dog House radars may be deployed – or be intended to be deployed – in a manner that would enable any shortcomings of the Griffon missile vis-à-vis Spartan to be overcome. Many people would disagree with this hypothesis, however, pointing to the use of aerodynamic control surfaces for in-flight guidance of the missile as suggesting insufficient manoeuvrability for missile interception.

LAND BASED ANTI-AIRCRAFT FIRE CONTROL SYSTEMS

ITALY

2233.151
INDIGO INTEGRATION KIT

DESCRIPTION:

The purpose of this integration kit is to augment the facilities provided by the Superfledermaus fire-control system (**2376.151**) to provide the additional target acquisition and missile control facilities required for an Indigo anti-aircraft missile system.

Included in the kit are the following major sub-systems:

1. X-band pulse doppler acquisition radar Type LPD-20
2. Command transmitter
3. Infra-red tracker
4. Guidance computer
5. Launcher computer
6. Launchers and power units

– all except the first and last of which are mounted in the Superfledermaus trailer.

OPERATION:

The target acquisition radar has a detection range of approximately 20 km on a two-square-metre target, and is used to put on the Superfledermaus radar. The infra-red tracker and command transmitter are mounted on the antenna of this tracking radar so that if at any time during the operational sequence interference or equipment malfunction causes the tracking radar to lose the target or the missile's beam-riding guidance to fail, the infra-red tracker and command transmitter are already laid on the target and the Indigo missile's alternative command guidance can be brought swiftly into action.

Data from the tracking radar is processed to provide signals that are used to train the launchers so that the missile comes rapidly into the radar beam for beam-riding guidance. For command guidance the guidance computer processes the data from the tracking system to produce signals for the command transmitter.

Details of the Indigo missile and a schematic illustration of the complete system can be found in the Indigo entry in Section A2b (**2235.131**).

DEVELOPMENT:

Development of the Indigo system was started as a private venture by Contraves Italiana SpA in 1962. In 1969 the missile project was transferred to Sistel SpA but development of the fire control system was continued by Contraves. The Superfledermaus, of course, was developed by Contraves AG, Zürich.

A prototype of the integration kit has been tested by the Italian Army with a Contraves fire control system. The manufacturers are now ready to put it into series production.

MANUFACTURER:

Contraves Italiana SpA, Via Tiburtina 965-00156 Rome.

THE NETHERLANDS

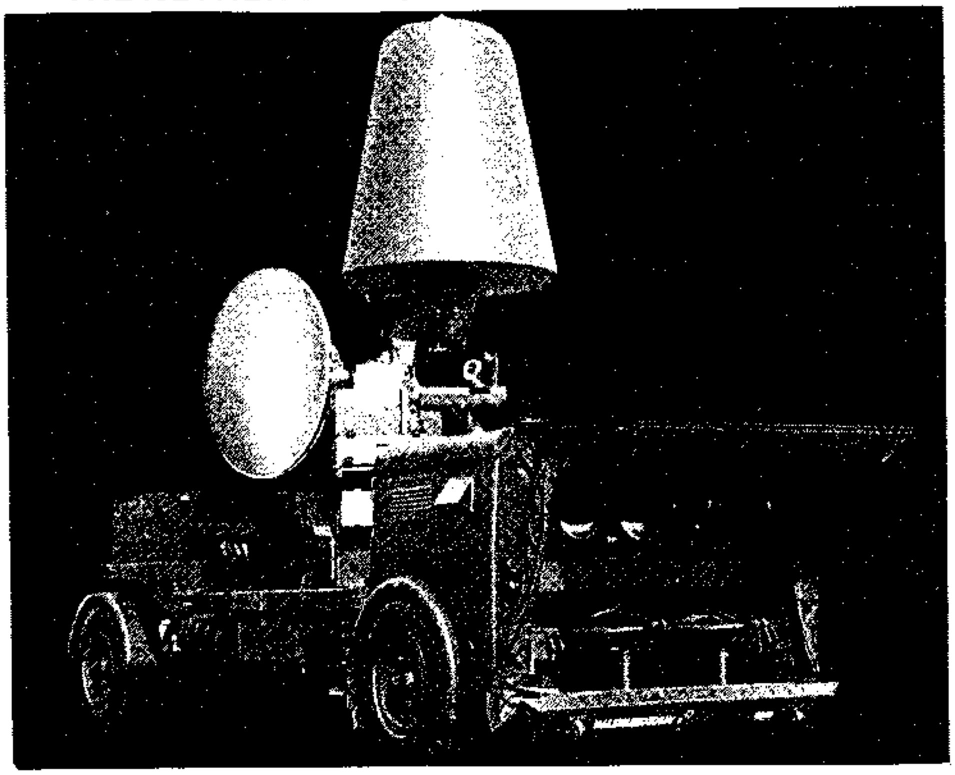
2300.151
L4/5 WEAPON CONTROL SYSTEM

DESCRIPTION:

Signaal's L4/5 Weapon Control system has been developed for the close air defence of vital points such as airfields or bridges. It incorporates a digital computer and a high-power radar; and although it was originally designed to control 40-mm AA guns it can easily be adapted to control guided missiles or for remote control target indication by inter-console marking.

An important feature of the system is understood to be its FASCAN search principle which is said to ensure the detection of even very low-flying aircraft. Other features include a short over-all reaction time, resulting from the use of a digital computer, and a high degree of mobility comparable with that of the 40 mm guns that it was designed to control.

The complete system is mounted on a four-wheeled trailer, the antenna pedestal, which carries both surveillance and tracking radar heads and optical sights, being mounted in the centre of the trailer. The remainder of the electronic equipment is located at the rear of the trailer. In transit the surveillance aerial is hinged down to the horizontal and the equipment cabin is closed. In operation the equipment cabin opens to provide a platform with two seats for the operators and a small canopy; normal practice being to shroud this with a cover so that the operators can work in near-darkness.



L4/5 Weapon System

DEVELOPMENT:

Extensive field trials of the system were carried out in 1962-3 and 1965 and proved highly successful and the system is in series production.

Signaal are working on more mobile versions of this system for guided missiles and towards complete self-propelled weapon systems (see also **2350.181** below).

MANUFACTURER:

N.V. Hollandse Signaalapparaten, Hengelo, Netherlands.

2301.151
FLYCATCHER (VL 4/41) AA WEAPON CONTROL SYSTEM

DESCRIPTION:

Flycatcher is a versatile AA radar weapon control system designed to detect, identify and automatically track aircraft flying at very low to medium altitudes. It can be used to control either guns or missiles.

Main elements of the system are a dual retractable search and track antenna system, a radar transmitter-receiver, a radar display and control assembly, a fire control assembly and a digital computer. The whole system is housed in a transportable rectangular container. Power consumption is about 6kVA.

Full performance details are not available but it appears that the system is intended to engage targets in a zone of 10-20 km radius. Up to three gun or missile installations can be controlled independently by the computer.

The radar is an X-band system and features track-while scan, a high data-renewal rate and a multiplicity of ECCM and anti-interference facilities. The search antenna is a slotted waveguide; the tracking antenna is parabolic with a Cassegrain reflector and a monopulse feed horn.

The computer can handle targets with horizontal speeds up to 500 m/sec and vertical speeds up to 300 m/sec and can perform ballistics computations for light-calibre guns.

CHARACTERISTICS:

Function: All-weather point and area defence with AA guns and S/A missile against medium- to very low-level air attacks

Sensors: X-band search and tracking radar, optical target indicator

Weapons: Up to three weapons, being either all guns (30, 35, 40 mm) or guns and one S/A missile (command line-of-sight or semi-active homing); parallax distance up to 500 m

Search Coverage: Up to 20 km (1 m^2 target) track while scan

Display: PPI, North oriented, clutter-and interference-free, scales 10/20 km

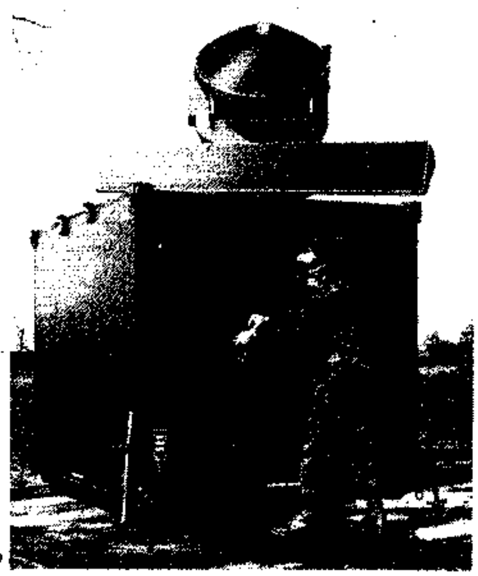
Target engagement: Joystick indication, automatic acquisition and tracking, highly automated weapon control

ECCM: Simultaneous with clutter rejection, (details classified)

System design: Container construction, retract-

able antennas, self-contained petrol-driven power supply, removable wheel-train, micro-miniaturised solid-state electronics
Dimensions: Length 2.73 m, width 2.12 m, height (antenna in): 2.13 m (antenna out): 3.65 m
System weight: 2,300 kg (approx)
Environmental: Operating temp. −40° to +52°C, storage temp. −55° to +71°C, operating height up to 2,500 metres above sea level; others according to MIL-STD-210A, ground equipment, worldwide; vibration and shock capabilities based on MIL-S-52059A

MANUFACTURER:
N.V. Hollandse Signaalapparaten, Hengelo, Netherlands.



VL4/41 AA Weapon Control System

SWEDEN

2378.151
BOFI ANTI-AIRCRAFT FIRE CONTROL SYSTEM

DESCRIPTION:
BOFI is the name of a fire-control instrument developed by Bofors, which is intended for their 40 mm L/70 mobile gun (**5528.103**) of which large quantities have been produced. BOFI is an abbreviation of Bofors Optronic Fire-control Instrument. The equipment in its entirety is mounted on the gun, and is integrated with its functions. The system is of the clear-weather type, and can be used for combating targets both in daylight and darkness.

The main parts of the system consist of a combination day and night sight, a laser range-finder, a computer, and control devices with panel. The major portion of the equipment is placed in a cab, which can be provided with heating and air-conditioning equipment. The power required is obtained from a power-supply unit mounted on the gun. A separate power-supply unit can also be used.

The sight consists of a conventional, monocular sight, combined with a passive night glass. The same ocular is used for both sights. The operator can quickly switch from one sight to the other, which is an advantage at dawn and dusk. The night glass consists of receiver optics, followed by a 3-stage light amplifier. The range-finder consists of a neodymium laser with a pulse frequency of 10 pulses per second. The laser is provided with devices for blocking off echoes at close range, and the receiver has a gate which is controlled from the computer, which gives excellent anti-jamming properties. The computer is of a hybrid type, and calculates supporting signals to the aiming system, so that the operator need only make minor corrections.

BOFI system mounted on 40 mm gun

The system can receive target data either from an optical target indicator deployed in connection with the gun, or from a separately deployed search radar.

This fire-control equipment is designed in such a way that it can also be used on existing 40 mm L/70 guns on field carriages.

STATUS:
User trials of the system were carried out during 1972, in co-operation with the Swedish Armed Forces, and it is now operational.

MANUFACTURER:
AB Bofors, S-690 20 BOFORS, Sweden.

SWITZERLAND

2376.151
SUPER-FLEDERMAUS

A member of the series of anti-aircraft fire control systems produced by Contraves in Switzerland, the Super-Fledermaus Type Dix with MTI is an advanced radar optical tracking and computing system suitable for use with medium calibre anti-aircraft guns and missiles. Extreme operational versatility coupled with compact and rugged design make it suitable for use in a wide variety of combat situations, and it and its forerunners are used by more than twenty nations.

The main equipment is compactly mounted on a four wheel cross-country trailer and comprises a radar/visual tracker for target acquisition and tracking; an electronic computer for continuously determining the firing data for up to three separate gun emplacements; and a muzzle velocity indicator for measuring the muzzle velocities of up to three guns. A separate power supply unit, mounted on a two-wheel trailer, generates power for the fire control unit. Available as auxiliary equipment are a signal box for use by the Fire Control Officer and an optical putter-on for rapid visual acquisition of unexpected targets.

A detailed description of the system was published in the 1970-71 edition of Jane's Weapon Systems

CHARACTERISTICS:
Type: Combined radar/visual tracker and computer for remote control of medium calibre anti-aircraft guns or missiles
Target Detection: Up to a range of 50 km
Target Acquisition: All-weather operation with five options:
(a) by selectable programmed scanning motion
(b) by optical putter on
(c) by optical tracker

(d) by tactical radar
(e) by radar/visual combination

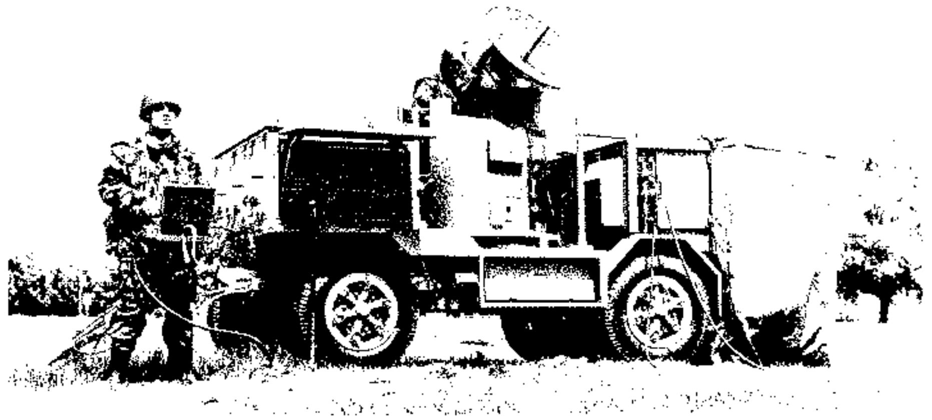
Target Tracking: Up to a range of 40 km with five options:
(a) automatically by radar
(b) automatically by regenerative control
(c) automatically by memory
(d) visually by tracker operation
(e) automatically in range: visually in angle

Firing Data Computation: Continuous computation individually for three gun emplacements
Muzzle velocity and meteorological connections included
Special modes selectable for diving or curved flights

Muzzle Velocity Measurement: Separate measurement by built-in equipment for each gun

ECCM:
High transmitting power
Narrow main beam
High sidelobe attenuation
Two independent transmitting channels
Jump changes of frequency over wide band
IAGC
STC
FTC

Clutter Suppression: MTI data processor
Mobility: Cross-country trailer
Maintenance: Built-in test and calibration equipment. Use of modular plug-in units



Super-Fledermaus anti-aircraft fire-control system

MANUFACTURERS

Complete system	Contraves AG, Zurich, Switzerland
Fire Control Radar	Siemens-Albis Aktiengesellschaft, Zurich.
MTI Equipment	Telefonaktiebolaget LM Ericsson, Göteborg.
Muzzle Velocity Measuring Equipment	Oerlikon Machine Tool Works Buehrle AG, Zurich.

The system is also manufactured by Contraves Italiana SpA, Rome, Italy, and under licence in India and Japan.

2377.151
SKYGUARD ANTI-AIRCRAFT FIRE CONTROL SYSTEM

Skyguard is the name now given to the miniaturised fire control system that Contraves have been developing for some time as the successor to the Superfledermaus (**2376.151**) system that they have marketed so successfully in various versions for many years.

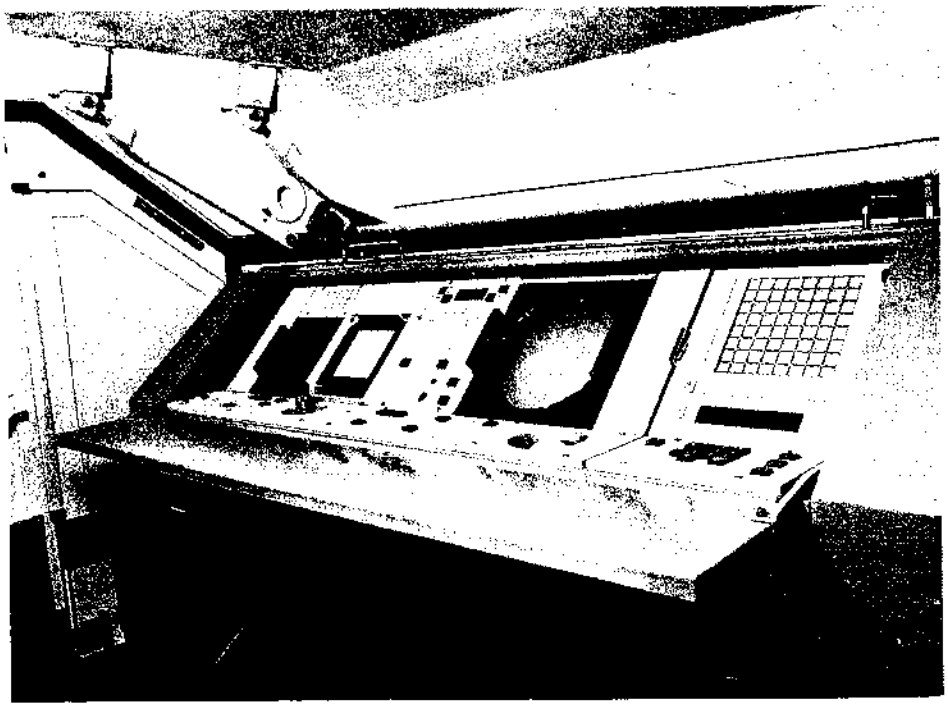
Major differences between Skyguard and its predecessors – apart from a general modernisation of design techniques – are the provision of two radars (one for search and one for track) in place of one and the use of a digital instead of an analogue computer. Another important difference is the use of pulse-Doppler type radars in place of pulse radars.

DESCRIPTION:

Main system components are a pulse-Doppler search radar, a pulse-Doppler tracking radar, a TV tracking system, a digital computer, a control console and a power supply system. The whole is contained in a fire resistant reinforced fibre-glass-polyester cabin that can be mounted on a trailer or a wheeled or tracked prime mover, and is air transportable. The power supply system is built into the main equipment but can be removed for external operation and is automatically refuelled directly from cans.

The search radar is a fully coherent pulse-Doppler equipment, the transmitter of which is common to the tracking radar. Working in X-band with a mean power of 200W it offers fast frequency change and fast p.r.f. change facilities and a choice of 1 and 0.3 microsecond pulses. A Cassegrain cheese antenna gives a beam width of 1.7 degrees in azimuth and 35 degrees in elevation and scans at 60 rev/min. The receiver has range-gated Doppler filters and offers an MTI improvement factor better than 50dB. The PPI display has switched ranges from 0.3 km to 20 km and can present simultaneously processed MTI video and raw video. Radar search range is 20 km and range resolution 160 metres. The system is IFF-compatible and special features include automatic target alarm, automatic lock-on and computer-controlled symbol markers on the PPI.

The tracking radar is a fully-coherent monopulse-Doppler equipment with a Cassegrain paraboloidal antenna having a 2.2 degree beam-width. Signal processing circuits provide 80-metre acquisition gates around the tracking gate, all gates having Doppler filters, and the total acquisition range is 1,120 metres. The MTI im-



Skyguard control console showing, right to left, Input-output panel with matrix-field; PPI Display presenting all necessary information to the commander; Rolling-ball for manual target assignment; Tactical numerical display (top); *Weapon control panels* (bottom); *TV Monitor and video-processor; TV Controls; Joy stick for manual control of tracker; ECCM-Panel* (bottom)

Skyguard in operational configuration on M584 carrier

Skyguard in trailer-mounted version, showing method of folding away radar antennas provement factor is better than 50dB. The display is an A/R trace, displayed on the TV monitor, for tracking supervision and ECM monitoring but target acquisition and tracking is automatic and includes memory tracking and automatic alarm facilities. Special features include fast target exchange, automatic noise jammer tracking and a second independent tracking system for range and angular error measurements.

A closed-circuit TV system provides for optical tracking and automatic TV tracking. An optical sight on a rotating chair is provided for visual target acquisition with provision for target indication by means of a flashing strobe on the PPI.

The Cora II M computer is a third generation equipment working in real time to perform threat evaluation functions, calculate ballistic data for guns and command signals for missiles, aid the target tracking operation and monitor and check-out the entire system.

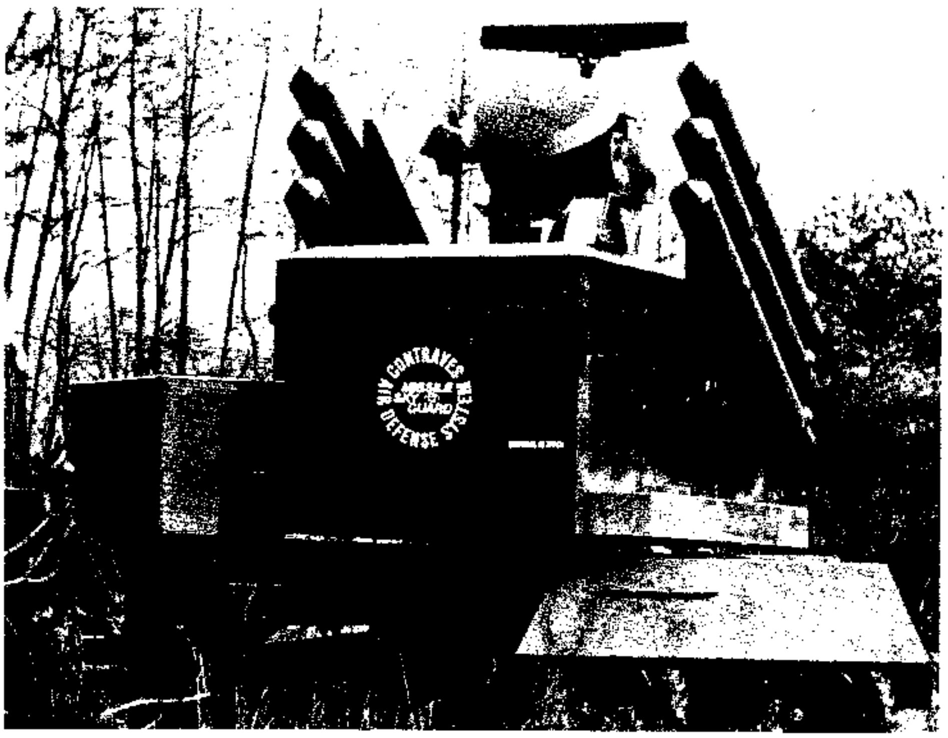
In addition to the PPI and A/R displays already mentioned, the control console incorporates a tactical display with numerical read-out, the TV tracking monitor, rolling-ball control for PPI markers, joystick control for manual tracking and a matrix panel for data input and output.

OPERATION:

The console is designed so that one or two operators can control Skyguard according to the tactical requirements of the situation.

STATUS:

Skyguard has been developed by Contraves as a private venture and was evaluated by the Swiss Armed Forces for several months in technical and tactical trials. In addition to the developed fire control system, Contraves have made proposals for an integrated weapon system called Skyguard-M which incorporates suitable missile launchers on the same tracked vehicle as that carrying the basic Skyguard.



Engineering model of Skyguard-M integrated weapon system

MANUFACTURERS:

System and Computer: Contraves AG, Zurich, Switzerland.

Radars: Telefonaktiebolaget L.M. Ericsson, Göteborg, Sweden.

NAVAL FIRE CONTROL AND ACTION DATA AUTOMATION SYSTEMS

BRAZIL

1665.281
NITEROI CLASS AIO

DESCRIPTION:

Following a contract signed in 1971, Vosper Thornycroft Limited are designing and building four 3,500 ton Mark 10 Frigates for the Brazilian Navy, and supplying all materials and components for a further two to be built in Rio de Janeiro. There are two different versions of the Mark 10 an Anti-Submarine (A/S) ship and a General Purpose (GP) ship, the major differences between the two being in the weapon outfits. Vosper Thornycroft are responsible for the design, integration and functioning of the complete Weapon and Action Information Systems, for which Ferranti Limited (Digital Systems Division) are the major subcontractor. Each ship is to be fitted with three FM 1600B computer systems (**1433.063**): one for Action Information Organisation and two for Weapon Control. More details of these appear in Entry No. **1524.281** in this section.

Artist's impression of Brazilian Niteroi Class Vosper Thornycroft Mk 10 frigate. Three Ferranti computer systems will be used for AIO and Weapon Control

ACTION INFORMATION ORGANISATION (AIO):

The AIO and sensor outfits are almost identical for both versions of the Mark 10, except that an Edo 700E Variable Depth Sonar (**2581.253**) is fitted to the A/S Ships.

A Plessey AWS-2 E/F band diversity surveillance radar (**1751.253**), with a stabilised antenna, provides long range above water surveillance. A Mark 10 IFF system is fitted in conjunction with this set.

For navigation, surface search and helicopter control, a Hollandse Signaalapparaten ZWO-6 I-band radar (**1555.253**) is fitted to the top of a foremast, giving clear all-round surveillance and a long horizon-limited range. Video from both these radars is processed by the AIO computer, which also controls the IFF system to give auto-decoding facilities. Auto extraction techniques allow a large number of targets to be tracked simultaneously with the primary radars.

The AIO system displays the tactical picture on six Deccascan CA1600 combined radar and synthetic PPI viewing units. Each of these units contains a horizontal CRT viewing surface incorporating a reflection plotter, and a keyboard unit by means of which data from the computer may be selected for display, and new information and orders injected. Radar selection and normal picture controls are also incorporated. The display is normally operated by two men, each of whom is provided with a tote read-out area on the PPI. This is used for read-in checking as well as output data display.

Passive detection of radar transmissions is provided by a Decca RDL 2/5 system (**1341.253**). This locates and analyses external radar signals, and also incorporates an automatic warning system which is triggered by reception of transmissions corresponding to certain preset characteristics.

Underwater surveillance and target tracking is performed by an Edo 610E panoramic medium-range hull sonar (**2580.253**) and, in the A/S ships, a compatible Edo 700E Variable Depth sonar.

A complex 'status interface' with the AIO computer permits maximum use to be made of the flexible Edo system, which provides a number of transmission and reception modes, selectable by the operator to suit environmental and tactical conditions.

Sonar information is supplied to the Weapon Control Systems as well as the AIO, where it is evaluated, corrected for propagation delays and other factors, and may be presented synthetically on the AIO displays. The Prediction for A/S Weapons is performed by the Weapon Control Computers.

The AIO System also solves tactical problems and provides information for the guidance of helicopters in MATCH anti-submarine attacks. Each ship carries one Westland WG13 'Lynx' helicopter (**1587.302**).

Data on target tracks selected manually for engagement by the ships' weapon systems are passed by inter-computer Data Highway to the Weapon Control Systems.

WEAPONS AND WEAPON CONTROL:

All frigates are armed with a Vickers 113 mm Mark 8 automatic gun (**6011.203**), two Bofors 40 mm guns (**6015.203**) and two triple Seacat AA missile launchers. In addition to the A/S helicopter, a Bofors twin 375 mm rocket launcher (**2368.203**), side launched torpedoes and a depth charge rail are fitted.

In addition to this, A/S ships are fitted with an Ikara anti-submarine missile system (**6002.241**), while GP ships are to have Exocet missiles (**1156.221**) as well as a second 113 mm gun.

Two Selenia RTN10X tracking radars (**1368.253**) are provided, one of which is fitted with CCTV for control of Seacat missiles (**1019.231**), in addition to the normal pedestal director. A stabilised Optical Look-out and Aiming Sight (LAS) (**1340.293**) is fitted in conjunction with each 113 mm gun, and may be used either as a Visual Director in conjunction with the computer system, or as a means of direct emergency control of the gun.

Control of the various weapons is divided between the two fire control computers in such a way as to minimise the tactical consequences should one computer fail.

A special version of the Ikara system is being developed for the Brazilian Navy and is known as 'BRANIK'. This system is the subject of a joint development programme by Vosper Thornycroft, Hawker Siddeley Dynamics and Ferranti. It incorporates a light-weight, semi-automated missile handling outfit and a special purpose missile tracking and guidance system, which is fully integrated with one of the FM 1600B fire control computers.

With the exception of the 40 mm guns, all the weapons mentioned above are deployed under full computer control. The 40 mm guns may be assigned to targets by means of a training signal derived from the AIO system. Thereafter engagement takes place under on-mounting operator control, aided by line of sight gyro stabilisation.

Operational control of weapons is carried out at special consoles situated in the Operations Room. Extensive use is made of Electronic Data Displays (EDDs) for data display and input of data and orders by light pen. This substantially reduces the number of special purpose controls, eases the operator's task, and improves reliability.

Medium speed data links are incorporated so that positions and supplementary track data may be exchanged between the computer systems of similarly equipped ships. Thus for example the 'BRANIK' system or A/S helicopter may engage targets which are not visible to the ship's sensors but are being tracked by another friendly unit.

STATUS:

The first of the "Niteroi" class is due to be launched in 1974, and an extensive programme of weapon system proving trials will commence in 1975.

MANUFACTURER:

Vosper Thornycroft Ltd, Vosper House, Paulsgrove, Portsmouth, England, PO6 4QA.

CANADA

2046.261
CCS-280 COMMAND AND CONTROL SYSTEMS (DDH-280) CLASS

DESCRIPTION:

A shipborne automatic data-handling and display system based on the Litton L-304 single processor version digital computer. Designated AN/USQ-501(V) Data Processing Set, it comprises one digital computer, eight multifunction displays and other peripherals as shown in the accompanying picture. Equipment was designed to and meets MIL shipborne environmental specifications. Solid state components are used throughout with extensive use of integrated circuits in computer and display modules.

The computer is fitted with a 40K 32-bit word memory capable of expansion to 80K words by addition of plug-in modules to the existing processor mainframe. Increased I/O capability can be achieved by adding units to the existing data bus using available minor channels in the I/O modules. The system includes radar signal simu lation, which provides superimposed or separate radar targets variable in size and brightness for training. Displays are multipurpose and identical. Quick action buttons (QAB) provide mode selection and independent selection of up to seven separate radar videos with independent offset and range scales 1-152 miles in binary increments. Category selection of symbology is programmable on-line, independently, at each display.

Basic operating software has been provided by the manufacturer. In the case of the CCS-280 the Canadian Armed Forces chose to write all the operational software in a programme generation facility provided by the contractor.

OPERATION:

The operational programme was designed and produced by a team of military officers, experienced in Anti-submarine Warfare. This programme blends the speed and processing power of the digital computer, the comprehensive, flexible display and the automatic data link equipment, into a system which provides real time co-ordination of sensors and weapons by the Command at the unit and force level to:

a. collect, process and display tactical information from all sensors.
b. control aircraft and other remote surface units.
c. direct own ship's and force weapons.
d. control own ship manoeuvres.
e. exchange information and orders within own ship and force.

DEVELOPMENT:

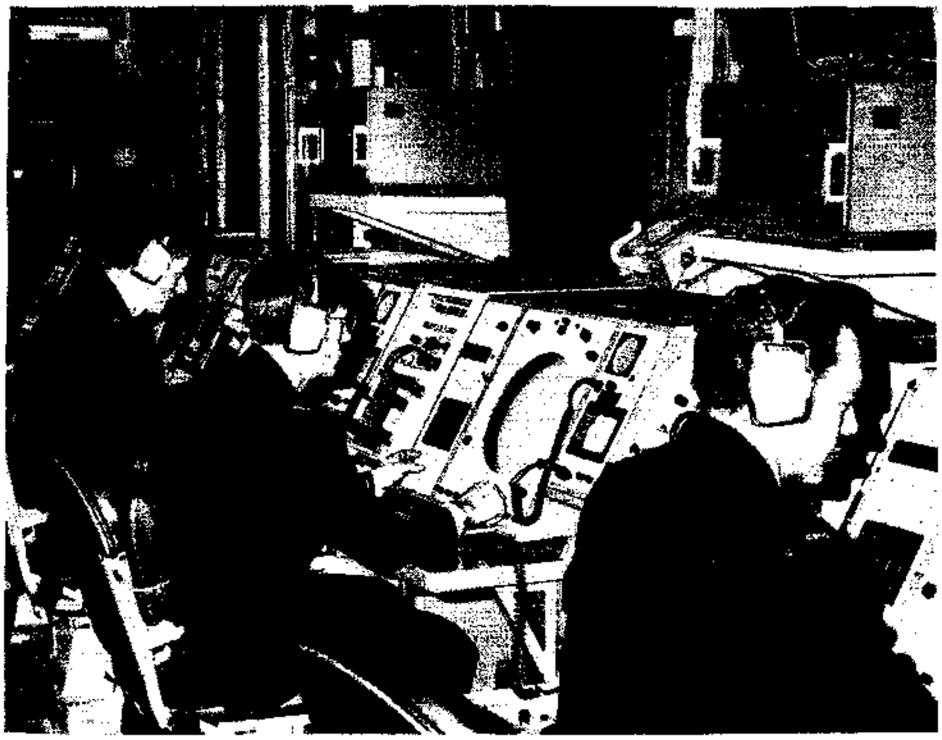
The hardware was developed and built by Litton Systems (Canada) Limited in conjunction with the Data Systems Division of Litton Industries to meet the functional requirements specified by the Canadian Armed Forces.

STATUS:

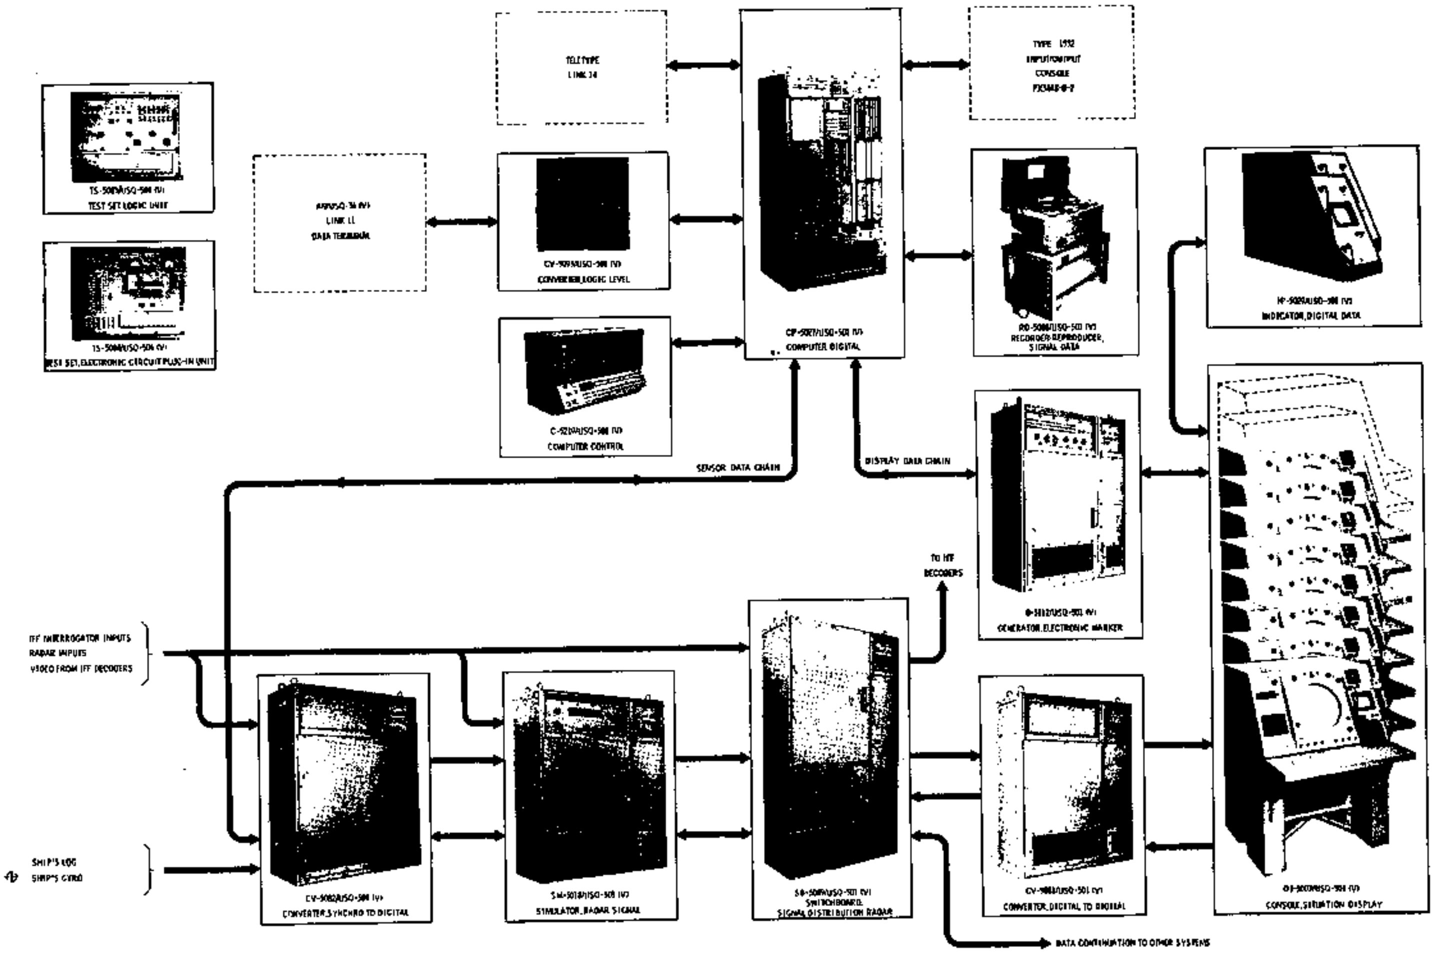
The system is currently operational at sea in HMC Ships, Iroquois, Athabaskan, Huron and Algonquin. A shore installation for training and programme maintenance and generation is fitted in the Combined Support Divisions, Halifax.

MANUFACTURERS:

Litton Systems (Canada) Limited.
Collins Radio (Automatic Link Equipment).



A group of situation display consoles of the CCS-280 Command and Control System on board HMCS Iroquois



2047.261
UNDERWATER COMBAT SYSTEM (UCS) 257/280

DESCRIPTION:

The UCS 257 and/or UCS 280 comprises two AN/SQS-505 Sonar Sets (**2038.253**), an Anti-Submarine Warfare Data System (ASWDS) and ancillary equipment for both Hull-Mounted (HMS) and Variable Depth Sets (VDS). Both AN/SQS-505 sonars are electronically identical and comprise a transmitter group, a receiver group, a control indicator group, and a transducer. The ancillary equipment for the hull-mounted set consists of a retractable hull outfit with dome. The ancillary equipment for the variable-depth set consists of the AN/SQA-502 hoist group (including tow cable) and a variable-depth body (including gyro compass).

The ASWDS is an action data system designed to accept primary target information from hull-mounted and/or variable depth sonars and secondary target information from radars. This information is processed by a high speed general purpose computer to provide action information to the command, computation of fire control solutions and weapon control.

A prototype of the system has been installed and evaluated in HMCS *Terra Nova*. Production models are fitted in HMC Ships *Terra Nova, Gatineau, Kootenay* and *Restigouche* all of which are anti-submarine DDE "Restigouche" Class destroyers commissioned to take ASROC. The AN/SQS-505 sonar system is installed in the four new DDH 280 class anti-submarine destroyers which have two helicopters, and in addition Mk 32 torpedo tubes fitted instead of ASROC

MANUFACTURERS (Production Units):

Canadian Westinghouse Co Ltd, Hamilton, Ontario, Canada – Transmitter, Power Supply, Sonar Transmission Control, Generator-Indicator and Range-Doppler Indicator.

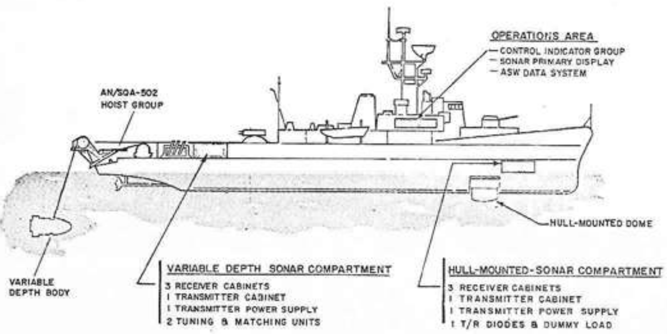
Edo (Canada) Ltd, Cornwall, Ontario, Canada (No longer in existence) – Receiver and Transducer.

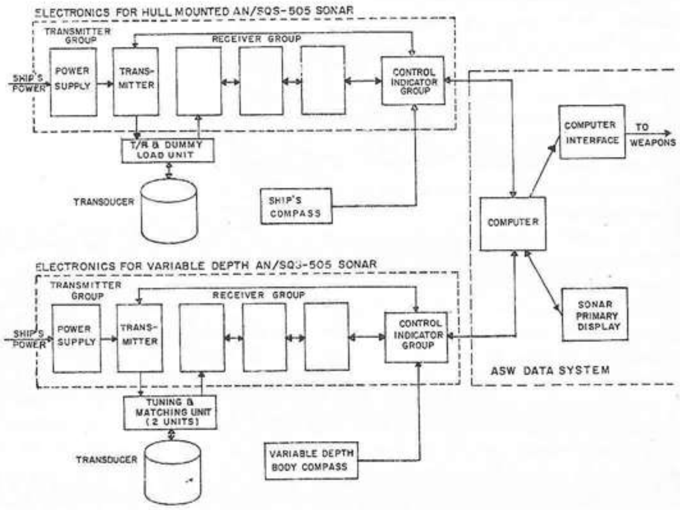
C-Tech Ltd, Cornwall, Ontario, Canada – T/R & Dummy Load, T/M Unit, Underwater Telephone Transfer Control Unit.

Standard Telephones and Cables Ltd, Newport, Monmouthshire, Wales – Tow Cable 5.

Fleet Industries Division, Ronyx Corporation Ltd, PO Box 400, Fort Erie, Canada L2A 5N3 – Hoist, body and VDS hoist mechanism.

N.V. Hollandse Signaalapparaten, Hengelo, Netherlands – ASWDS (Computer, Sensor Weapon Converter, Sonar Primary Indicator, Sonar Signal Injector).





FRANCE

1053.281
VEGA SERIES SHIP'S SURVEILLANCE AND WEAPON CONTROL SYSTEMS

DESCRIPTION:

Under this designation, Thomson-CSF produces a range of modular integrated naval systems.

The basic elements of a Vega system comprise:

- a choice of four combined air and surface surveillance and target designation radars
- a choice of two tracking radars
- a choice of two tactical information units
- one or more linked computers, according to the ship's radar, ASW and weapons fit.

Auxiliary and ancillary apparatus or other systems complementing the ship equipment are also integrated or associated with the Vega systems, namely: IFF, navigation radar, ECM, sonar, plotting table, optical sights or directors, vertical and heading gyros, log, etc.

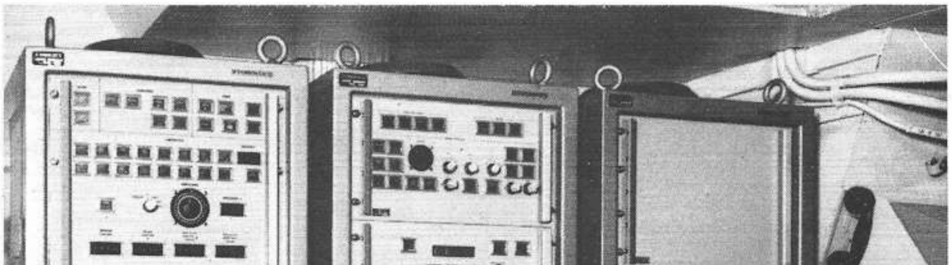
The weapons controlled can include:

- artillery of any calibre and rate of fire
- anti-ship missiles (Exocet, Otomat, Harpoon, Teseo, Penguin)
- surface-to-air missiles
- surface torpedoes
- ASW torpedoes
- ASW rockets.

RADARS:

Triton is a C-band combined air and surface surveillance radar (**1062.253**) especially designed to equip small tonnage ships. Its MTI version gives it a sea-skimmer missile detection capability. Its polarisation is linear horizontal.

Saturne II is an S-band air and surface surveillance radar (**1237.253**) incorporating an MTI receiver. It can be fitted with either one or the other of two antennae with both switchable linear and circular polarisation. One with a 3 m span, 10 and 20 rpm rotation rate and roll and pitch stabilisation, the other with a 4.5 m span, 12 and 24 rpm rotation rate and roll stabilisation. The transmitter features high peak and average power, two pulse



Operational console of a typical Vega Fire Control system for ships' guns and other weapons durations and two PRFs. The Saturne II detection capability includes sea-skimmer missiles.

Sea Tiger is a combined air and surface surveillance radar (**1687.253**). It incorporates a high average power, fully coherent transmitter for improved MTI performance, with two pulse durations and two PRFs. Its other important features are pulse compression, digital post integration, random frequency transmission for better anti-jamming performance. The antenna is roll stabilised, has a span of 4.5 m and switchable linear and circular polarisation. The Sea Tiger is particularly suited to the detection of sea-skimmer missiles.

Pollux is an X-band fast scanning fire control radar (**1064.253**). Its MTI version is provided with two PRFs and a filter with two switchable transfer characteristics. Its polarisation is circular.

Castor II is a monopulse X-band fire control radar (**1063.253**) with incorporated MTI receiver making it capable of acquiring and tracking a sea-skimmer missile of very small radar cross section within heavy sea clutter echoes. As Pollux, in its MTI version, it is fitted with two PRFs and two switchable filter transfer characteristics. Its polarisation is linear horizontal.

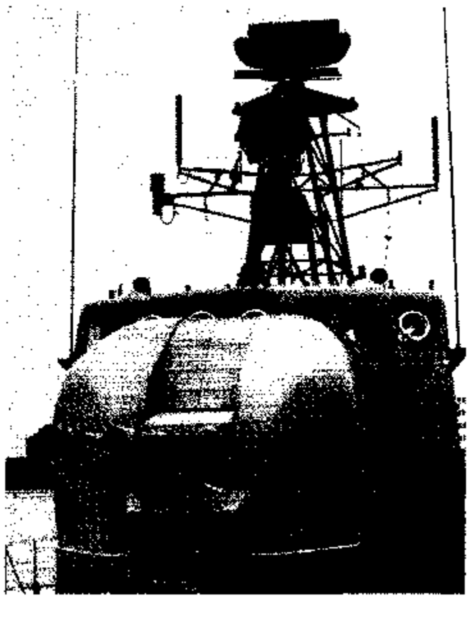
TIU:

Vega I and Vega II (**1779.281** and **1780.281**) are the two alternative tactical information units.

COMPUTER:

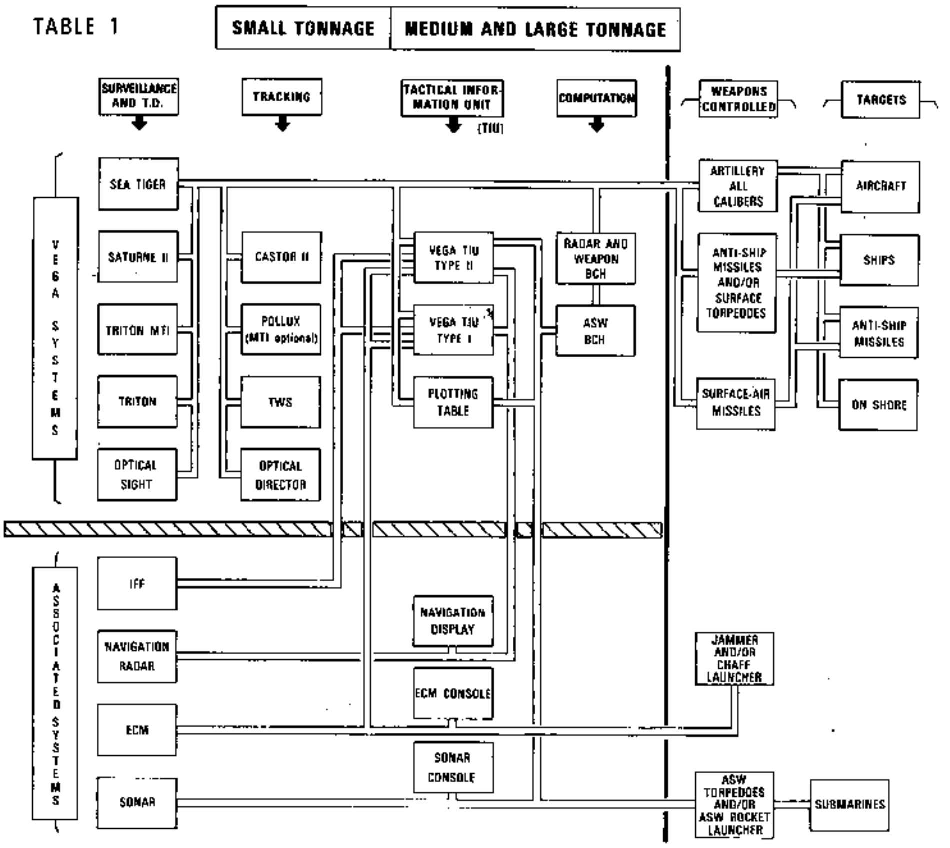
The Computer is the modular BCH which performs all the computations for the system, including some auxiliary functions such as azimuth stabilisation of display when an unstabilised surveillance antenna is used; control and stabilisation of the tracking radars in autonomous search mode; memory tracking; constant altitude tracking; elevation search; and ship speed compensation for MTI receivers.

In all instances, the surveillance and tracking radars are dissociated physically and in frequency range in order to reduce the vulnerability of the system and its basic susceptibility to jamming and to optimise each function. This also increases the range of possible surface or low altitude detection by allowing a higher location of the surveillance antenna. The MTI receivers are all of the linear digital type with a wide rejection bandwidth to cope with the speed and wide spectral distribution of the kinds of clutter encountered at sea. They incorporate an own-ship's speed compensation device.



Typical Vega-Pollux fire control system radar installation

Possible combinations in the VEGA SYSTEMS



VEGA SYSTEM TYPE I-43

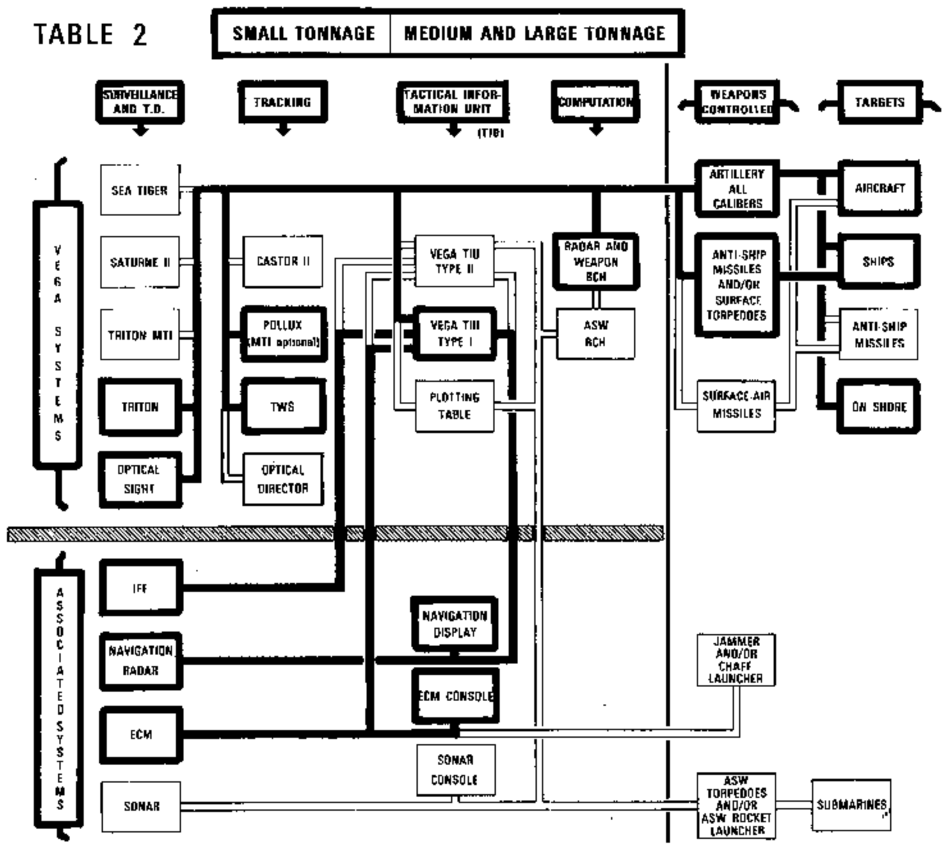


TABLE II: The Vega type I-43 system, intended for small tonnage ships or as a complementary system on a larger vessel. It consists mainly of the combination of a Triton surveillance radar, a Pollux tracking radar, TWS, optical sight, Vega I tactical information unit, and computer. It controls artillery and the launching of anti-ship missiles and/or surface torpedoes. The possible targets are aircraft and on shore for artillery and ships for missiles and artillery. Only an ECM analyser and alert receiver are associated with this example of system, but this could be extended to a jammer and/or chaff launcher. Also included are an IFF and a navigation radar

The tracking radars are designed to avoid the need of a radome, which makes possible the addition of TV cameras or TV tracking devices which are also available for integration with the fire control systems. According to the weapon fit, the tracking radars, tactical information units and computation means can be chosen independently of the ship's tonnage, when the surveillance radar and sonar are more closely linked to it.

The possible combinations of equipments and weapons are summarised in Table I. Three Vega configurations are also shown as typical examples in Tables II to IV.

STATUS

Development of the Vega systems started in 1967. The first system manufactured, a Vega type I-43, controls the following weaponry: two guns, Exocet missiles and AEG SSi4 torpedoes. It has been operational since the end of 1971. From the early Vega systems, mostly adapted to small tonnage ships, to the systems presently available, the evolution has been towards an enlargement in the choice of basic equipments to meet the requirements of a broad range of tonnage and missions, with a particular emphasis on the self defence capability against sea-skimmer missiles. To date, more than sixty Vega systems are either operational or in production.

MANUFACTURER:

Thomson-CSF, Division Radars de Surface, 1 rue des Mathurins, 92222-Bagneux, France.

VEGA SYSTEM TYPE II-73

TABLE 3

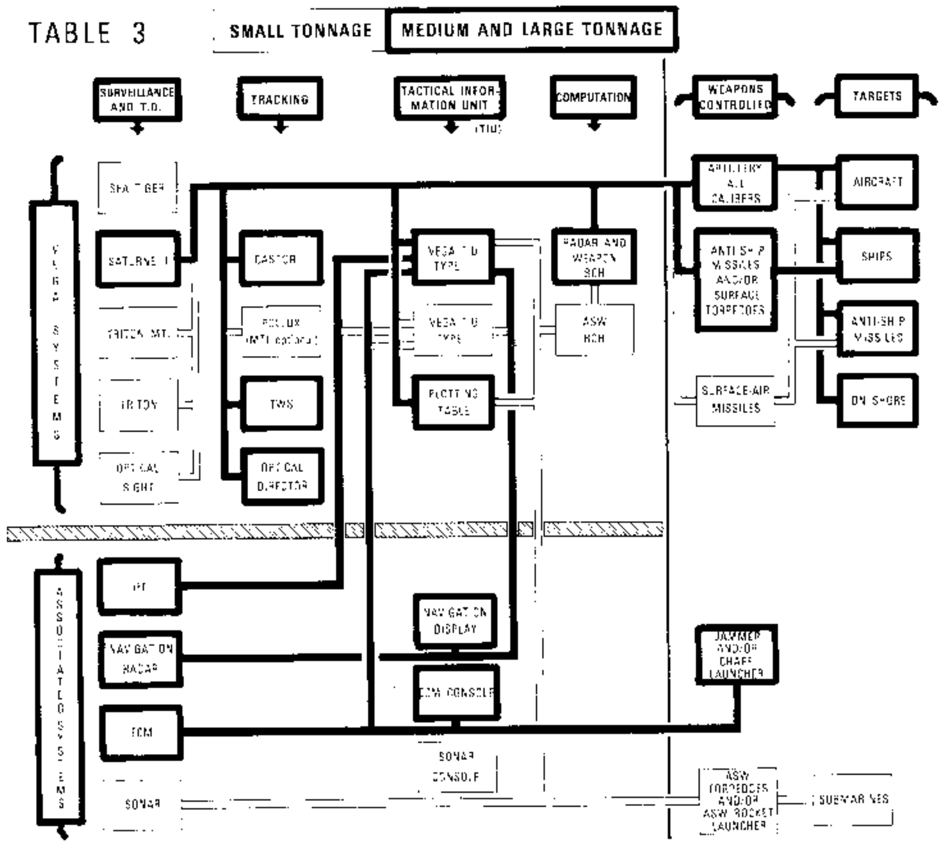

TABLE III: The Vega type II-73 intended for a medium to large tonnage ship. It includes a Saturne II surveillance radar, Castor II as tracking radar, an optical director, TWS, Vega II tactical information unit and a computer. An IFF, a navigation radar and ECM sub system are associated. The controlled weapons are artillery, anti-ship missiles and / or surface torpedoes. This system has the capability of artillery fire control not only against aircraft, ships, or shore targets, but also against sea-skimmer missiles, by the use of the Saturne II surveillance radar and Castor II tracking radar

VEGA SYSTEM TYPE II-89

TABLE 4

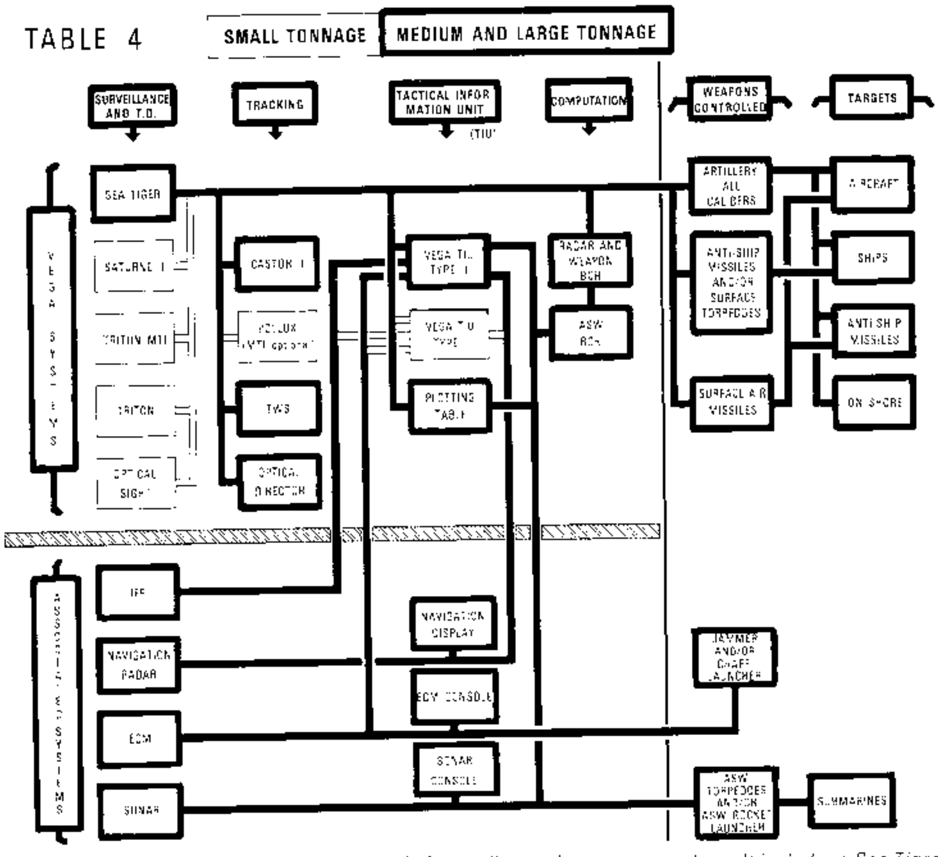

TABLE IV: The Vega II 89 system, is suitable for medium to large tonnage ships. It includes a Sea Tiger surveillance radar, one or more Castor II tracking radars, the Vega II tactical information unit, one or more surface weapon computers according to the number of tracking radars, optical director, plotting table IFF, navigation radar, ECM and ASW are associated. This system controls artillery, anti ship missiles and / or surface torpedoes and surface-to-air missiles. It can handle all kinds of targets, including sea-skimmer missiles with the detection and tracking capabilities of respectively the Sea Tiger and Castor II radars, and submarines through the association of a Sonar, ASW computer and ASW weapons

1779.281
VEGA TACTICAL INFORMATION UNIT TYPE I

DESCRIPTION:

This code name has been given to the operational use equipment employed in Thomson-CSF Vega systems for radar data display and system operation. The Vega tactical information unit Type I comprises conventional display consoles for manual operation and for automatic plot tracking of 1 or 2 surface targets. Vectors and electronic markers represent data delivered by the TWS, units, the fire-control radar, ECM devices, optical sight units, etc. Manual target designation is achieved by electronic marker. Presentation can be of either the relative-motion or the true-motion type. Data processing is carried out by the BCH computer of the Vega system.

STATUS:

Entry into operational service in 1969.

MANUFACTURER:

Thomson-CSF, Division Radars de Surface, 1 rue des Mathurins, 92222-Bagneux, France.

1780.281
VEGA TACTICAL INFORMATION UNIT TYPE II

DESCRIPTION:

The Vega tactical information unit Type II is an automated data processing system for use on board all-tonnage ships, in place of the Vega Tactical Unit Type I, for the purpose of improving decision making and shortening the overall reaction time of the system. It permits the following actions:

- acquisition of data describing the real-time situation;
- shaping, sorting and display of these data, aids to situation evaluation;
- designation of targets to weapon systems and transmission of engagement orders;
- resolution of tactical problems;
- transmission and reception of data to and from external ships (or aircraft).

OPERATION:

The following data sources are exploited: radar, IFF, sonar, passive detection (ECM), optical detection, gyrocompass, log, and external sources. To reduce manual filtering and plot linking operations, the system performs automatic tracking of 16 air or surface targets or, in difficult conditions, rate-aided manual following of radar tracks. The display of the tracks followed is completed with symbols, identification letters and numbers, velocity vectors, etc.

To facilitate and speed up the operator's decision making, the system offers such operational facilities as true motion, target designation and reports, and enables the resolution of a number of tactical problems: azimuth-range, interception time, CPA (anti-collision) track extrapolation (time to go), etc.

The Vega Tactical Information Unit Type II comprises 2 to 6 operation consoles which are multipurpose and hence interchangeable, this making it possible to adapt operational facilities to the actual situation at any moment, by designating each position for a well defined use, eg: command, surface surveillance, air surveillance, weapon allocation, etc. The consoles are fitted with a 16-inch high-quality display, and control panel with selection devices: numerical keyboard, order keyboard, electronic alidade vector control devices.

The Vega TIU Type II is controlled by the digital computer of the Vega system, this being fitted with supplementary input/output facilities and supplementary programs.

STATUS:

Under development.

MANUFACTURERS:

1522.261
SENIT NAVAL TACTICAL DATA HANDLING SYSTEMS

DESCRIPTION:

The French Navy's naval tactical information systems for surface vessels are identified under the acronymic designation SENIT (Systéme d'Exploitation Navale des Informations Tactiques), and five systems of this kind have been identified. All five have the broad functions of gathering, coordinating and distributing sensor data and other information, presentation of information on appropriate displays, and certain weapon system control functions. A digital computer, or computers, provides the central processing facilities. The five systems differ in accordance with the nature and operational role of the vessel fitted and the sensors and armament installed.

SENIT 1:

This version is fitted to the two "Suffren" Class guided missile frigates, *Suffren* and *Duquesne* (D602 and D603), which are armed with a twin launcher for Masurca surface-to-air missiles (**1177.231**), a single Malafon anti-submarine weapon launcher (**1179.241**), two single 100 mm AA guns, two single 30 mm guns, and four torpedo tubes. Sensors fitted include a DRBN 32 surveillance/navigation radar, a DRBI 23 three-dimensional air surveillance and target designation radar, two DRBR 51 target tracking and missile guidance radars for the Masurca system, an X-band gun fire control radar, two visual tracking sights, a DUBV 23 hull sonar, and a DUBV 32 variable depth towed sonar.

Three computers are employed in the SENIT 1 system. An IBM machine accepts data from the DRBI 23 radar and carries out air target threat evaluation and presents target position and height information to displays in the operations room. Target data is also available to weapon systems. Another IBM computer is used as the Masurca launch computer. A version of this system is under development for the anti-aircraft cruiser *Colbert* (C611) which will be armed with a twin Masurca launcher, two single 100 mm AA guns, and six twin 57 mm AA guns. Sensors will include a navigation radar, DRBV 23 air surveillance and target designation radar, surface surveillance radar, height finder radar, two DRBR 51 Masurca fire control radars, one fire control radar for 100 mm guns, and two fire control radars for 57 mm guns. The *Colbert* will also have a hull-mounted sonar.

SENIT 2:

This version is to be produced in two forms to equip vessels intended for (1) fleet air defence, or (2) as radar picket ships in support of the French STRIDA national air defence network. The SENIT 2 system employs one computer only, probably a Hughes machine. Known fittings, completed or in progress, are the four ships of the T 47, "Surcouf" Class; converted to carry the Tartar surface-to-air missile system (**6006.231**), D622 *Kersaint*, D624 *Bouvet*, D625 *Dupetit Thouars*, and D630 *Du Chayla*; three radar picket ships of the T 53R class, D634 *Le Bourdonnais*, D636 *Tartu*, and D637 *Jaureguiberry*; and A633 *Duperre*, which is now classified as experimental.

The Tartar fitted vessels have Hughes SPA-72 air surveillance and target designation radars which incorporate their own digital computers, and fire control radars for missiles and guns. The radar picket ships have DRBI 10 and DRBV 22 search radars, and X-band fire control radars. Five other vessels of the T 47 class are being modernised and equipped for anti-submarine duties but it is not yet known if these are to be provided with SENIT systems. SENIT 2 was developed in collaboration with the West German Navy.

SENIT 3:

The SENIT 3 system is fitted to the corvette Aconit and is planned for the two Type C67 A corvettes *Tourville* and *Duguay-Trouin* derived from the *Aconit* and now under construction. The *Aconit* is armed with Malafon anti-submarine weapons, one quadruple A/S mortar, torpedoes, and two 100 mm AA guns. The later vessels will carry a total of 13 Malafon missiles, six MM 38 Exocet anti-ship missiles (**1156.221**), two torpedo launchers (12 anti-submarine L5 torpedoes), and three 100 mm gun mountings. Each vessel will carry two WG 13 helicopters which will be capable of use in an anti-submarine role with Mk 44 torpedoes and grenades, or against surface targets with AS 12 missiles (**1174.311**). Sensors fitted to C67 A ships include a combined surveillance radar DRBV 13, one fire control radar N 32, one navigation radar, a helicopter deck landing radar, bow and variable-depth towed sonars, and electronic counter-measures.

The SENIT 3 is intended principally for use in the anti-submarine and anti-shipping roles, but will also provide for quick reaction against air targets for defence. Two computers are employed, with expanded memory facilities. The computer equipment is provided by Univac, and it works in conjunction with a display sub-system by Hughes which is produced under licence in France by Thomson-CSF.

SENIT 4:

This version, and the SENIT 5, are new systems now under development and both employ computers of French design and manufacture. SENIT 4 employs the IRIS 55M (**1422.063**) computer in conjunction with ten Vizir displays developed by SINTRA. Each of these display consoles has a potential capacity of up to 130 track symbols with speed vectors, an information display with twelve lines of 18 characters, four circles, 23 lines or target vectors. The consoles are provided with tracker balls and keyboard data entry facilities. The synthetic information display has a character repertoire of 96 different symbols.

Vessels to be fitted are the aircraft carriers *Clemenceau* and *Foch* and the new C 70 class of corvettes.

SENIT 5:

SENIT 5 has a somewhat lower overall capacity than SENIT 4 and is intended for handling the tactical data requirements of small and medium tonnage ships, in which neither the cost nor the capacity of the larger system can be justified. The computer used is the IRIS 35M (**1423.063**) with a variety of peripheral and additional storage options. The display sub-system comprises the same Vizir display consoles as used in SENIT 4, but in this case they are connected to the IRIS 35M via an interface unit which also provides a similar service for the sensors. A typical complement is five display consoles and two sensors. Up to 40 targets can be accommodated by the system, and there are provisions for the presentation of supplementary data in alpha-numeric and symbolic form. A PLAD automatic data plotter can also be connected to the system, and there is provision for the use of data link between consorts, aircraft or the shore.

A total of fourteen vessels of the *Aviso* C 70 class of coastal protection and surveillance ships is expected to be fitted with the SENIT 5 system. Two versions of this class have been projected, for coastal protection and for anti-submarine duties. Weapons will include Exocet, sextuple A/S mortars, twin torpedo tubes and 100 mm guns.

1353.281

HIRONDELLE AIR DEFENCE SYSTEM

DESCRIPTION:

Hirondelle is a naval air defence system with the protection of ships from attack by very low-level air- or ship-launched missiles as its principal design objectives. For this role, it is essentially a short range system, with all-weather capability.

The main elements of the system are surveillance and tracking radar to provide for target designation and illuminating of targets at heights of a few metres; a fire control system and associated data processing facilities; one or more missile launching ramps, each equipped with four or eight missiles in watertight containers. The system would also include provision for the direction and control of ship's guns in addition to Hirondelle missiles. The latter will be a version of the Matra Super 530 air-to-air weapon (Entry No. **1349.331**).

Design of the system permits its use on ships of 200 tonnes or above.

STATUS

It was stated that the system had reached the design stage in May 1971, this being performed by Electronique Marcel Dassault. No hardware details have been released.

Model of French CMN Combattante II class vessel with Hirondelle short-range surface-to-air missile system. (Mid-ships launcher/containers are for surface-to surface missiles)

1232.281

ALCATEL DLT-L-4C TORPEDO LAUNCH CONTROL SYSTEM

DESCRIPTION:

The DLT-L-4C system has been designed for the launching of L.3 type torpedoes from surface ships, a typical application being escort vessels of the French Navy. These ships have two triple launching platforms, one on each side, and two triple cases for the storage of reserve torpedoes.

The system performs the following functions

Reception of target data provided by sonar and conversion of this data into parameters suitable for launch calculations.

Geometric and kinematic resolution of the launch, and development of parameters required for the L.3 torpedo.

Selection of the platform and tube to be used for launch.

Transmission and checking of remote control commands to the selected torpedo.

Control and monitoring of firing.

A complete DLT-L-4C system comprises a torpedo launch control station (PCLT), and a number of interface boxes distributed throughout the launch tube platform assemblies. The latter provides the requisite electrical supply and control links between the PCLT and the various mechanical elements of the system.

The PCLT is located in the ship's operations centre, and groups all the controls and indicators needed for launching. Two modes of launching are provided for: Normal – automatic calculation of launch parameters. Emergency – parameters displayed.

Data employed in the calculation of launch parameters includes, azimuth, inclination, target speed, distance and bearing.

The parameters transmitted to the torpedo are gyro-deflection angle, time of trajectory, reference submersion depth.

MANUFACTURER:

CIT-ALCATEL, Division Marine, 33 rue Emeriau, 75 275 Paris Cédex 15-France.

1739.461

DLT-D-3A SUBMARINE TORPEDO FIRE CONTROL SYSTEM

DESCRIPTION

The CIT-Alcatel DLT-D-3A torpedo fire control system is designed as a replacement for the DLT-S-4 system in French "Daphne" Class submarines. It is intended for firing most of the old and new types of torpedoes employed by the French Navy. The Daphne class submarines have eight forward torpedo tubes for firing eight types of torpedoes, and two groups of two aft tubes; two pairs of external tubes each firing two types of older mode, torpedoes.

Target data is fed to the system from on-board sensors, which comprise fore and aft sonars; fore and aft microphone clusters; the DUUX 2 acoustic range-finder; attack and surveillance periscopes.

Data processing and distribution is carried out by an IRIS 35M digital computer (Entry No. **1423.063**), the principal functions of which are as follows From the sensor information, target components such as azimuth, range, speed and course are computed, and the determination of target elements can be performed by any of three different methods. It can be carried out simultaneously for two targets. Two firing paths can be computed simultaneously, for the direction of two different torpedoes against a single target, or towards two different targets.

Provision is made for remote setting of torpedoes prior to firing, consisting of on-off presetting as well as continuous (servo) presetting. Other facilities are fire command and control, and automatic and manual guidance of wire torpedoes.

The above operations are performed by means of the IRIS 35M computer and a display and command console. The latter provides for manual input/output functions and constitutes the sensor-calculator interface. The unit has three CRT displays, for tactical situation, firing path presentation, and tabular data, respectively. Two control keyboards provide for overall control over the complete system.

The various units of the DLT-D-3A system are located in three areas; operations room, forward tube section, and aft tube section. In the operations room are:

Display and command console. VIC.1

Calculator QTD X

Ancillaries (junction box BJG3, azimuth relay RZ1, tape reader LEC1, computer control desk PCQ1, cut-out CDG3)

In the forward tube section the equipment consists of ancillaries and the PAT 2 tube control and selection desk. This permits torpedo checking and maintenance, and includes signalling preparatory to firing and selection facilities for the eight tubes

A similar arrangement of equipment is made in the aft tube section, where the PAT 3 tube control and selection desk provides facilities for the operation of four tubes employing old-model torpedoes only.

STATUS:

At late development stage. Another version, based on the DLT-D-3A will be fitted in 1,200-ton class submarines.

MANUFACTURER:

CIT-ALCATEL Division Marine, 33 rue Emeriau, 75 275 Paris Cédex 15-France

1309.481

SUBMARINE TORPEDO FIRE CONTROL SYSTEM DLT-S-4E

DESCRIPTION:

This system has been designed for installation in the French Navy Daphne Class of submarines for the control of French torpedoes such as the Z16, E12, E14, and L3. It is stated to be suitable for adaption, to other submarines and types of torpedoes.

The elements of a DLT-S-4E installation are located at three stations in the submarine: Central Operations, Bow tube sections, and Aft tube section. The principal units at the Central Operations station are:

ALG1-2. Power Supply and Data Drive: This provides the power supplies for synchro circuits and other signalling functions from the ship's main 115V three-phase 60 Hz supply. It also includes provision for torpedo fire control under the following conditions: Stop, Reheating, Navigation, Surveillance, and Combat.

RZ-1 Azimuth Relay: This provides azimuth reference information for the complete system, derived from the ship's data sources.

GZ-2 Azimuth Plotter This gives a record of all the azimuth data derived from the submarine's detection sensors, and also has arrangements for the presentation of certain selected bearings on the relative-track plate (plotter).

PRR-2 Relative-track Plate This permits the display of relative track-axis determined on the basis of the data supplied by the azimuth plotter. It processes and transmits the parameters of this axis to the QFZ 1 computer, and the CONJ-1 conjugator for determining target vector by the azimetric method

CONJ-1 Conjugator: This unit receives the target position, bearing and range data from the shipboard detection equipment, and can process target speed and course vector by manual stabilisation, tachymetric, or azimetric methods. Computed target data is transmitted to the trajectory computer, QTL-3.

QTL-3 Trajectory Computer This computer calculates the firing parameters from the data supplied by the conjugator and the displayed torpedo elements. It computes the trajectories for various torpedoes that can be used. These are, linear for the E-12, E-14, and L.3 torpedoes, and linear with or without a sinuous trajectory for the programmable Z 16 torpedo.

Both the fore and aft tube sections are provided with AL 2 Power Supply units which provide power, signal interconnections, and emergency firing facilities. The bow tube section also has a Bow Combiner CAV-3 for the assigning of tubes to the several launch channels.

OPERATION:

Detection sensors providing inputs to the system are, the surveillance and attack periscopes, fore and aft sonars Type GCO2, the DUUX-2 listening set, and probably a radar such as the Thomson-CSF Calypso (which see). Range and bearing data available from these sensors are recorded simultaneously on the azimuth plotter where they are plotted as a graph against time, and also transmitted for navigational purposes. The trace produced by successive bearings of a designated target on the azimuth graph permits its relative track to be determined and this is displayed by the Relative Track Plate.

Target information and relevant own ship data are transmitted to the Trajectory Computer which performs the launch calculations on the basis of the type of torpedo selected. In the case of the Z.16 weapon, it computes all the parameters needed for the execution of the torpedo's sinuous trajectory, while for the acoustic L.3, E.14, and E.15, torpedoes, the optimum approach trajectory is computed. Torpedo preparation orders are transmitted to the weapons in their tubes.

Attack methods by the three categories of torpedo are.

A. Use of programmed Z.16 torpedoes against isolated or convoyed surface vessels:

Gyro-controlled steering enables the target to be attacked at the most effective angle of incidence.

The optional sinuous trajectory increases the probability of a hit.

Tele-control of torpedo depth as a function of target draught.

Magnetic proximity detonations, or inertial contact detonation.

Electric propulsion gives a speed of 30 knots over a distance of 10,000 metres.

Group firing of two Z.16 torpedoes enables a substantial danger zone to be produced.

B. Use of passive acoustic torpedoes E.14 and E.15 against snorkel submarines and surface vessels:

Linear approach and search trajectory.

Pursuit trajectory by passive auto-director using target-generated noise.

Tele-controlled, constant depth.

Magnetic proximity and contact detonation.

Electric propulsion gives a speed of 25 knots over distances of 10,000 metres (E.15) or 5,000 metres (E.14).

C. Use of the active L.3 torpedo against submerged submarines:

Linear approach trajectory without transmission from the acoustic homing head.

Activation of the homing head and sinuous search trajectory increases the probability of target detection.

Tele-controlled search depth according to estimated target depth.

Underwater acoustic pursuit in the horizontal plane.

Proximity and contact detonation.

Electric propulsion gives a speed of 25 knots over a distance of 5,000 metres.

MANUFACTURER:

CIT-ALCATEL, Division Marine, 33 rue Emeriau, 75 725 Paris Cédex 15-France.

GERMANY (FEDERAL REPUBLIC)

1824.291
AGIS COMBAT INFORMATION SYSTEM

DESCRIPTION:

AGIS (Automatisiertes Gefechts- und Informationssystem für Schnellboote) is a fully integrated command and fire control system which has been developed for the West German Bundesmarine's new Type 143 fast patrol boats. The principal sub-systems of AGIS comprise: radar, optical and probably EW sensors; computer; display; data link; and fire control system. The ship's weapons consist of four single fixed launchers for Exocet surface-to-surface missiles (**1156.221**), Seal wire-guided torpedoes (**2000.441**), and two Oto Melara 76/62 compact dual-purpose guns (**5533.203**). It is intended that Type 143 ships will operate as flotilla leaders, in consort with Type 142 and Type 148 fast patrol boats for instance, and the scale of data processing, display and communications facilities provided reflects this. Within the last of these categories are HF and VHF transmitter receivers, UHF encoding transmitter/receivers, and teleprinter links. Display arrangements provide for two torpedo control consoles, a gun control console, a horizontal conference-type tactical display and a vertical tactical plot.

The radar sensors are those of the Hollandse Signaal M27 integrated fire control system (**1359.281**) which forms a large part of the overall AGIS installation. Within the single spherical radome that is characteristic of this series of FCS are stabilised antennas for air and surface search and target tracking, and with integrated IFF/SIF facilities. The Type 143 is provided with a separate navigation radar, other navigation equipment including an echo-sounder, log, Decca Navigator and horizontally stabilised gyro-compass. The optical director is a Galileo type OGR-7/3.

STATUS:

The first of ten Type 143 vessels was laid down at the Lürssen yard in Bremen-Vegesack in April 1972 and has since been launched and begun trials. This ship is due to be handed over to the Bundesmarine in November 1975, "operationally and functionally ready for service".

To ensure this, and because of the particular significance of the electronic systems and equipment, AEG-Telefunken was appointed main contractor.

MANUFACTURERS:

AEG-Telefunken, 7900 Ulm, Elisabethanstrasse 3, West Germany – Main contractor.

N.V. Hollandse Signaalapparaten, PO Box 42, Hengelo, Netherlands – M27 FCS.

1825.281
SATIR ACTION INFORMATION SYSTEM

DESCRIPTION:

SATIR (System zur Auswertung Taktischer Informationen auf Raketenzerstören) is the tactical data automation and display system fitted in the three Lütjens Class guided missile destroyers of the West German Bundesmarine. These ships are a modified version of the American Charles F Adams type and are fitted with US radars such as the SPS-52 three-dimensional search and target designator, SPS-10 surface warning set, SPS-40 air surveillance, and SPG-51 fire control radars for the Tartar surface-to-air missiles. Weight and space considerations decided the Bundesmarine against the installation of the US NTDS (Naval Tactical Data System) and SATIR was developed in its stead to meet the German requirement and in general compliance with the B-2 Concept, a NATO standardised system for destroyers and above. Beyond the participation of Univac, no other reliable details have been obtained.

ITALY

1823.281
ITALIAN NAVY MULTI-PURPOSE ROCKET CONTROL SYSTEM (UCLAR)

DESCRIPTION:

The UCLAR control system, with the Breda rocket launcher and Snia Viscosa chaff and illuminating rockets, forms the SCLAR multi-purpose rocket system recently fitted in some Italian Navy ships and due for installation in others. The main functions of the system are: (a) passive defence against radar-homing missiles by the 'chaff-rock' technique, and (b) visual fire-control in night surface operations with small and medium calibre guns through the use of 'star-rock' illumination. Basic features of the overall system are summarised as follows:

Rockets:

Multirole 105 mm rockets, with folding tails, designed for carrying chaff warheads and, on request, HE-type warheads.

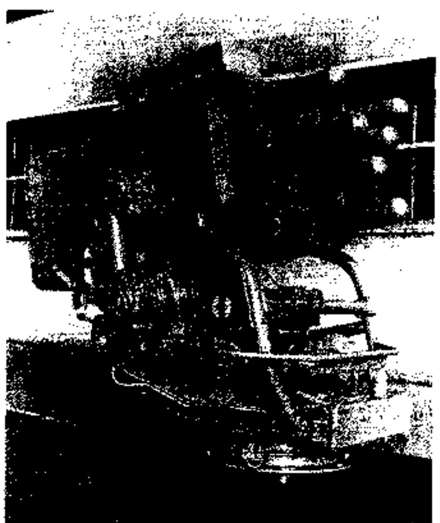
Range: up to 12 km.

The rockets are loaded each packed in a fibreglass launching container, the pre-fragmented hard plastic cap of which is broken by the projected rocket when fired. In so doing, the rocket cannot be affected by environmental conditions and at the moment of firing leaves in the same condition as when finally tested at the factory.

A high precision electronic fusing system (Italian Navy fuse) makes it possible to fulfil the programmed explosion figures at any preselected range and height.

Rocket launcher:

Two rocket launchers, installed on board symmetric to ship centre-line, each with 20 launching tubes, arranged in four horizontal rows and with its own Fire Sequence Programme Unit on the mount rotating part.



Breda launcher for Italian Navy SCLAR multi-purpose rocket system

ULCAR – Rocket Launcher Control Unit:
This receives from the designation sources the available data concerning the launching to be effected; operates launching data computation as a function of target range, ship motion and rocket ballistics. It operates two launching programmes:

Manual for long-range chaff dispensers;
Automatic for short-range chaff dispensers.

ULCAR:

The ULCAR provides launching data computation as a function of target designation data, ship motion and rocket ballistics, taking into account the launcher stabilisation as a function of deck-tilt and wind effect on the rocket flare. Rocket fuse setting is continuously and automatically operated.

The following data has to be manually introduced by the UCLAR operator in order to obtain the required computations: flare burst height; chaff dispenser burst height; spotting corrections for illuminating launches; absolute wind intensity and true bearing; train changes for programmed long-range chaff dispenser launches; increment of range (beyond target) for illuminating mode.

The UCLAR enables its operator to have overall control of the SCLAR by means of the following indications of the operational state:

Launcher servo "on"
Launcher under remote control
Launcher loading
Launcher ready
Numerical display of rockets on "pad" and type of rockets loaded on each row of "pad"
Selected launcher
Designation from Combat Information Centre, Electronic Warfare Centre or Target Indication Sight
Rocket launcher on "train mechanical limits"
Recommended ship course (to port or starboard)
Firing modes: Illuminating mode – Single long-range chaff mode – Programmed long-range chaff mode (multiple launching) – Short range chaff mode (multiple launching).

Having given orders for loading or completing the loading of the launchers, with indication of type of rocket and row to be loaded, and having accepted the automatic designation from CIC or EWC or TIS or having set manual input of target data, the UCLAR operator can, by pushing a button, fire one rocket or a sequence of rockets according to the preselected firing mode.

Launching of illuminating rockets:
The target is designated by the TIS's or the radar repeaters in CIC or from any other source by either direct or phone communication. The UCLAR operator sets star rocket burst height, increments range and wind correction, and then provides for starting of launcher servos and firing of rockets.

During firing, spotting correction can be added manually.

Launching of long-range chaff dispensers:
The target is designated by the radar repeaters in CIC or by the passive interceptors in EWC.

Two different modes can be selected:

(a) Single launching: a single launch for each firing order from UCLAR is accomplished. In this case, range and bearing of the target are taken into consideration.
(b) Programmed launchings: a number of consecutive launchings (up to five) for each launcher is accomplished. The launching sequence is range programmed by the UCLAR operator, who can also manually introduce a shifting in bearing to obtain a deception chaff pattern.

Launching of short-range dispensers:
The target is designated by the interceptor in EWC or by the TIS's. The UCLAR operator introduces head burst height and provides for chaff dispenser firing.

Four fixed-range launches are automatically accomplished: two right hand and two left-hand with respect to target bearing.

A four-point chaff pattern is thus obtained, with the diagonal axis at +45° to target direction.

The pattern is obtained a short time after fire button operation by the UCLAR operator.

LAUNCHER:

The Breda multi-purpose rocket launcher mount is designed for easy fitting in most types of ship and for the launching of rockets for different tasks: illuminating rockets, long and short-range chaff dispenser rockets, HE warhead rockets.

The launcher consists of:

Servoed mount, remote controlled for training and elevation.

The elevating launcher "pad" with its trunnion axis supports 20 tubular track cells. These cells are arranged in four horizontal rows, and are suitable for launching 105 mm rockets with folding tails, each loaded complete with individual watertight containers.

The "pad" is easily interchangeable with others suitable for launching rockets of a different type.

In the 20-cell "pad" the rockets are loaded as follows:

1st row: 5 illuminating rockets or long-range chaff dispensers.
2nd row: 5 illuminating rockets or long-range chaff dispensers.
3rd row: 5 long or short-range chaff dispensers.
4th row: 5 long or short-range chaff dispensers.

In each row, every rocket is electrically connected to the SCLAR by means of one plug-in multicontact connector which provides for firing circuit, for input to electronic fuse system and for signalling the type of rocket loaded in the row. An electronic device, Fire Sequence Program Unit, placed on mount rotating part provides for the selection of rockets to be launched, in accordance with the UCLAR orders, and the firing of rockets loaded on that row, for the counting of the rockets loaded when so ordered by the UCLAR operator.

In addition, the FSPU operates, in the SCLAR, as an automatic self-control device, allowing the system to fire only the rockets corresponding to the preselected types. In each row, the rockets not conforming to the preselected type are not reported as present in the numerical display on the UCLAR and on the Local Control Panel, and the firing input by-passes the rockets which do not correspond to those preselected, as in the case of misfired rockets.

The launcher has electric servo-systems for controlling bearing and elevation, employing solid-state servo-amplifiers.

ROCKETS:

The type of rocket used is a surface-to-surface ballistic vehicle, and was developed by Snia Viscosa to Italian Navy requirements. There are two versions: (a) long-range for chaff, illuminating and bombardment roles, and (b) short-range for chaff only. A high precision electronic fusing system receives continuous data direct from the firing director and initiates at the pre-selected time payload ejection from the flying rocket or head burst.

DEVELOPMENT:

The SCLAR system is the latest development in the field of rocket systems sponsored by the Italian Navy. The work was carried out in collaboration by Elettronica San Giorgio, Breda Meccanica Bresciana and Snia Viscosa.

STATUS:

The first operational installations, aboard the Italian "Audace"-class frigates were made in 1972, since when progressive fittings to other ships are understood to have taken place.

MANUFACTURERS:

ELSAG – Elettronica San Giorgio SpA, Via Hermada, 6-Genova-Sestri, Italy – ULCAR.

Breda Meccanica Bresciana SpA, Via Lunga, 2-Brescia, Italy – Launcher.

Snia Viscosa, BPD Division, SpA, Via Lombardia, 31-Rome, Italy – Rockets.

1020.281
NA9 SHIP'S FIRE CONTROL SYSTEM

DESCRIPTION:

Designed to provide fire control facilities for cruisers, frigates, corvettes and light vessels for the control of small and medium guns against air, sea or land targets. It is also capable of the control of missiles such as Seacat.

OPERATION:

The radar normally used is the Selenia Orion 250 which is used to provide range, bearing and elevation data on sea or air targets. This is normally used for automatic tracking, but a secondary tracking mode using manual methods is possible, using the raw target information provided by the radar. Operating frequency is in the X-band and a conical scan pattern is employed. Two-axis stabilisation is provided for the scanner. Radar tracking is supplemented by a pair of binocular telescopic sights, each of which can be remotely controlled by a joy-stick at the operator's position. The sight lines of radar and both optical sights are under the control of a computer which provides compensation for ship's pitch and roll. The computer also is responsible for the radar scanning pattern according to the mode of operation selected.

A crew of three is normally employed, one man for each optical sight and one for the radar. However, if the optical search mode is dispensed with, automatic operation is possible with one man only, whose main function is that of decision taking. All target information from other sources such as the ship's surveillance radar etc are supplied automatically. Target co-ordinates can be inserted from either stabilised sources or can be indicated relative to the ship's deck. Once the target has been aligned by the operator, using PPI, B and Az-El displays, automatic tracking is initiated by depressing a foot pedal.

Special measures taken by the designers to increase the effectiveness of the system when used for controlling conventional guns against aircraft targets include, automatic aiming correction as a function of distance and the intruder's flight parameters; self-checking and error correction facilities; and the use of special circuitry to overcome the problems inherent in low-angle target acquisition and tracking.

Quoted performance figures state that, with a target approaching at speeds up to 600 metres/sec and an angular velocity of 6/deg sec, the average miss distance at ranges between 1,000 and 4,500 metres is of the order of 8 m.

DEVELOPMENT:

The NA9 fire control system was derived from the ARGO system designed for the Italian Navy for installation on some of its newer vessels, in particular its guided missile cruisers.

STATUS:

The first of some 23 NA9 systems ordered for the Italian Navy and certain other navies entered service in 1964, and production of the NA9 series was completed by 1969. The successor system is the NA 10 (**1550.281**).

MANUFACTURER:

Elettronica San Giorgio – ELSAG – SpA, Via Hermadan, 6, Genova Sestri, Italy.

1550.281
ARGO NA 10 FIRE CONTROL SYSTEM

GENERAL:

In the light of the good performance in service over the past few years by 23 Argo NA 9 Systems installed on ships of different classes, the Italian Navy awarded a contract in 1969 to ELSAG – Elettronica San Giorgio (formerly Nuova San Giorgio) for another 13 Argo Fire Control Systems of the second generation, to be installed on new ships under construction. The systems, called ARGO NA 10, represent the natural evolution of the NA 9 FCS and a further development of it. Leaving unchanged the basic operational and technical features, already extensively evaluated, the Argo NA 10 System was achieved in accordance with the latest advanced technology to obtain further major benefits:

(a) to face more efficiently the increasing new threats (Sea Skimmers and ECM)
(b) to increase system operating modes (track-on-jam; TV, IR and laser sensors; missile guidance capability)
(c) to decrease weights and space requirements

Argo NA 10 Systems (at present, more than 25 systems are under manufacture or in the course of delivery, for the Italian Navy and for foreign Navies) are made in two versions:

NA 10 Mod 0: for installation on ships where several weapons of different natures may be controlled by the same FCS, also against different targets (air and naval targets).

NA 10 Mod 1: specifically designed for small craft equipped with surface-to-surface missiles and small-calibre guns.

ARGO NA 10 Mod 0:

DESCRIPTION:

Main characteristics of the NA 10 Mod 0 System are:

Use of three stabilised lines of sight (two optical and one radar), with provision for a third line of sight, for autonomous low level sectorial programmed search and independent tracking;

Use of closed circuit TV, day-light or low-light-level, according to customer requirements for monitoring automatic radar tracking or optical manual tracking;

Automatic target acquisition capability;

Double ballistic sections for guns of two different calibres;

Double fire control mode for shore bombardment (open and closed loop);

Control of three sets of guns;

Easy integration with data handling systems;

Easy reciprocal integration of two or more Argo Systems on same ship, so as to achieve an immediate quick action "network" against targets detected directly at close range.

The NA 10 System is equipped with an Orion RTN 10X type Radar, manufactured by the Selenia company. This is a pulse radar, X-band, narrow beam, fully transistorised, with ECCM capability. As an alternative to Orion RTN 10X Radar, the Orion RTN 16X monopulse Radar can be supplied.

The Main Control Unit provides a compact housing for: operational console with the radar displays and TV monitor; ballistic computer for air firing and surface bombardment; programming section for autonomous search and a complex array of data acquisition and data processing equipment specifically designed for enhancing the performance of the FCS, in quick acquisition and tracking of low flying targets also in natural interference or intentional ECM.

From the experience gained in retrofitting the previous Argo NA 9 System in order to make it suitable for Sea Sparrow missile control (Albatros project), The NA 10 Mod 0 System has been designed for easy integration, by simple addition of kits, with units relating to the control of missiles with semi-active guidance modes. The CW radar, provided for Sea Sparrow guidance and installed in the same tracking radar antenna pedestal, can also be employed in the general operating modes of FCS for enhancing the performance in point defence and anti-missile firing.

OPERATION:

The inputs to these fire control systems are: target data from radar and optical directors, true wind data from true wind computer, own ship speed and course from log and gyrocompass, roll and pitch data from a vertical reference, designation and tactical instructions from a target designation system or more sophisticated data action system. The outputs are gun orders for simultaneous pointing of guns, also of two different calibres, and signals for missile control system. A second target can be engaged using the raw target information provided by a search radar and optical tracking, performed by a periscopic optical sight. A crew of three is normally employed when the FCS is equipped with two periscopic optical sights, for autonomous search, independent optical tracking and missile optical guidance such as Seacat. However, a single operator at the Main Control Unit may perform acquisition, tracking and firing in manual or in automatic mode.

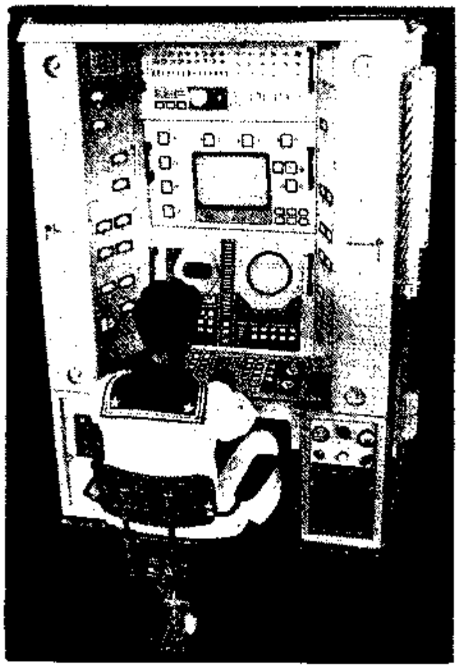
STATUS:

The first Argo NA 10 Mod 0 FCSs had been delivered at the beginning of 1971.

ARGO NA 10 Mod 1:

DESCRIPTION:

This version has been specifically developed in order to fulfil both operational and technical requirements of small craft, where the reduction of sizes and weights is a necessity. The FCS is intended mainly for anti-air and naval firing, but one mode of shore bombardment has been retained (open loop). In the NA 10 Mod 1 systems some functions and provisions of growth capability have been reduced in number with respect to the MOD 0. The radar employed is the Orion RTN 10X Radar, but the antenna mounting is lighter than in the MOD 0 system because it has been designed to carry only a radar antenna, a TV camera and a boresight with no provision for other sensors such as infra-red or laser sensor and CW radar for anti-air missile guidance. The periscopic optical sights are no longer part of the system; the programmed sectorial optical search can be performed by means of TV camera. The computer and other unmanned equipments, which in the MOD 0 system were included in the operational cónsole, have been located on MOD 1 in a separate cabinet so as to provide the maximum installation flexibility and conveniently suit any space available on board.



NA 10 MOD 1 Main control console

The total weight of the Argo NA 10 MOD 1 system is kept well within limits in line with small ship requirements. Should the armament so require, the NA 10 MOD 1 computer and console can be used in conjunction with the NA 10 MOD 0 radar antenna mounting.

Main functions are:

Programmed search

Manual or automatic acquisition

Tracking and firing control, by means of different operative modes, according to the type of targets and environmental conditions

Remote control of one or two sets of guns (single ballistic section and two output sections)

Designations and information (target speed data) to a surface-to-surface missile system

Special features are, high performance radar, low reaction time, high dynamic accuracy, and low flying target acquisition and tracking facilities.

STATUS:

The first ARGO NA 10 MOD 1 Fire Control System, ordered by the Italian Navy in 1971, was fitted in the Italian Navy PHM hydrofoil and later orders cover equipment for fast patrol boats of other navies. In early 1974 total sales of both versions of the NA 10 amounted to about 50 systems.

1920.281
DARDO SHORT RANGE DEFENCE SYSTEM

DESCRIPTION:

The Dardo system is a collaborative programme being carried out by Elettronica San Giorgio (Elsag) and Selenia, with the co-operation of Breda-Bofors. The latter concern is providing the weapon and special ammunition while the two former companies are jointly responsible for the radar, fire control, and digital computation elements of this ship's point defence system. Specific operational functions of Dardo include:

Defence against sea skimming anti-ship missiles.

Defence against diving missiles.

Defence against manned aircraft.

Effective ranges 300 metres to 3 km.

Few details have yet been obtained, but some of the special features of the system have been ascertained. Among them are the following:

The weapon employed is a Breda-Bofors 40/70 mm twin machine gun having a high rate of fire with specially developed ammunition for anti-missile applications and which is of the 'pre-fragmented' type. Further details of Breda-Bofors guns of this type will be found in Entries Nos **2258.203** and **2259.203** in the Equipment Section (Three) of this volume. Another entry which may contain information of some relevance to Dardo is **2349.131**, (Bofors 40 mm Anti-Aircraft System 75) which appears in an earlier part of this book dealing with land-mobile surface-to-air weapon systems.

In Dardo a radar of advanced design and optimised for tracking low-flying targets is employed. The system is stated to be designed for fully automatic operation by means of:

(1) Direct use of search radar information, with automatic data evaluation and target selection
(2) Automatic target acquisition
(3) Target tracking, automatically and with high performance in the presence of noise
(4) Automatic gun fire control

DEVELOPMENT:

The Dardo system had reached an advanced stage of development by October 1974 and the first contractual deliveries are scheduled for the end of 1976.

MANUFACTURERS:

Elettronica San Giorgio – ELSAG – SpA, Via Hermanda n.6, Genova Sestri, Italy.

Selenia – Industrie Elettroniche Associate SpA, Via Tiburtina km 12.4, Roma, Italy.

Breda Meccanica Bresciana SpA, Via Lunga 2, 25100 Brescia, Italy.

2230.281
AUTONOMOUS NAVAL FIRE CONTROL SYSTEM

DESCRIPTION:

Oto Melara are developing this system for use with small- and medium-calibre naval guns as a private venture.

Few details are as yet available, but the general principle of operation is clear. The basic idea is to provide, directly associated with the concerned gun, an electronic system that acquires target data, processes it and supplies appropriate control information to the gun, without reference to other systems on the ship. The system thus eliminates train-roller path plane tilt correction and parallax computations; it has lower weight than conventional fire control systems and offers improved reliability since only direct damage to the system can cause a shut down, whereas the usual FCS is vulnerable to damage to the links between FCS and gun.

The system comprises a search and tracking radar located in the upper part of the turret; an optional tracking system using a television camera with display adjacent to the radar display; and a computer. The computer processes the target data to stabilise the radar and optical lines of sight – eliminating the effects of the ship's motion – provides regenerative tracking and produces fire control data. Only one operator is required to man the system.

All system units use solid-state components so that the equipment is of low weight. The manufacturers also say that the system cost is low.

Test equipment will be supplied by the manufacturer.

DLB-1 ANTI-SUBMARINE WEAPON CONTROL SYSTEM

DESCRIPTION:

The DLB-1 system is designed to accept data from anti-submarine sensors, correlate and display this information, accept the tactical decisions of the operator and exercise ASW weapon control functions in accordance with the attack decided upon.

The equipment consists of a Main Control Unit, a Fire Pattern Programmer, and an Anti-Submarine Tactical Display. The first of these units supplies to sonars "aided tracking" data, and stabilising signals to the sonar transducer. It supplements the data provided by the sonar for delivering train, valve opening and fuse setting commands to an anti-submarine bomb-thrower. It also controls torpedo tubes. The computer is an analogue equipment.

The Fire Pattern Programmer computes and provides sequence signals for the firing of a salvo. The A/S Tactical Display presents all relevant data on the bridge.

The bomb-thrower employed is the K-113 manufactured by the Motofides company. This is a single-barrel weapon designed to throw depth charges for medium range operations. It is fully automatic and remotely controlled.

Sensors employed have all been American dual-purpose sonars such as the SQS-11, SQS-4, SQS-36, and SQS-29.

DEVELOPMENT:

First design studies were carried out in 1964, and the first fitting was on the Italian corvette *De Cristofaro*, in 1965. Studies now in progress are concerned with the provision of facilities for the control of anti-submarine rockets.

STATUS:

Twelve sets of the latest version of the DLB-1 are on order and nine have been delivered to the Italian Navy.

MANUFACTURER:

Electronica San Giorgio – ELSAG – Spar Via Hermadan, 6 Genova Sestri, Italy.

SEA KILLER INTEGRATION KIT

DESCRIPTION:

With the designation Sea Killer "Integration Kit", is generally meant those system units which have to be added to the Sea Hunter Naval Fire Control System, to provide missile launching and guidance capability for Sea Killer Mk 2 ship-to-ship missiles.

Such an integration kit has been designed and manufactured by Contraves Italiana, and consists of the following major sub-systems:

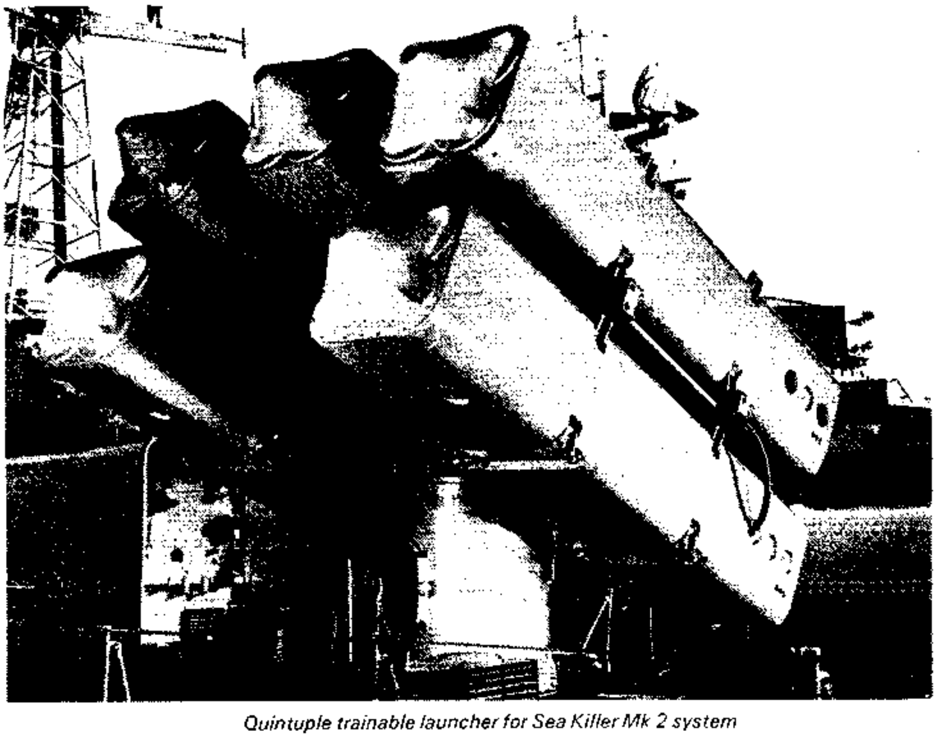
(1) Command Transmitter
(2) Quintuple trainable launcher or deck-fixed launchers
(3) Missile Control Console

The Quintuple Trainable Launcher serves to accommodate and launch the missiles, which are fitted to the launcher itself, located in their launching ramp/containers. The launcher is movable in two coordinates, training and elevation. It consists of a column fixed to the deck of the ship, over which the trainable section of the unit is mounted. A structure movable in elevation, supports the group of five cells, containing the missiles. The covers of each end of the missile containers are jettisoned automatically before firing.

MAIN FEATURES:

Training:

Arc: 360 deg (apart from blind arcs due to ship's superstructures etc)



Quintuple trainable launcher for Sea Killer Mk 2 system

Speed: approx 30 deg/sec
Acceleration: approx 30 deg/sec²
Elevation:
Arc: −15 deg to +30 deg
Speed: approx 20 deg/sec
Acceleration: approx 30 deg/sec²
Weight (with missiles and containers): approx 5 tonnes

While the quintuple trainable launcher allows a ship to launch missiles without changing course, deck-fixed launchers are more suitable for Fast Patrol Boats and similar light craft, due to their lower weight. In the case of deck-fixed launchers, the ship will have to be steered toward the target. This manoeuvre can be easily performed due to the high manoeuvrability of these light craft. In this configuration, additional minor units are required, such as the pilot's display unit, anemometric unit, and deck fixed ramps. A typical outfit is 4 ramps per ship. These units are supplied by SISTEL Sistemi Elettronici SpA, Rome, manufacturer of the Sea Killer Mk 2 missiles.

From the Missile Control Console, the whole Sea Killer Mk 2 system is operated by a single operator. The main functions are:
Selection of missiles for launch
Selection of guidance mode
Monitoring of system
Launching of missiles
Monitoring of the beam rider guidance
Guiding the missile optically with TV and joy stick

Manufacturer
Contraves Italiana SpA, Via Tiburtina 965, 00156 Rome, Italy.

Missile control console for Sea Killer Mk 2 system

1551.281
ALBATROS WEAPON SYSTEM

Albatros is an all-weather missile and gun shipborne weapon system designed for defence against aircraft and anti-ship missiles, including those flying at very low altitudes or having high diving angles. The system can also perform surface engagements by both missiles and guns, while the guns retain their usual capabilities (shore bombardment, illuminant firing, decoy dispensing etc).

The system can be installed in any type of vessel down to small escort units of some hundred tons displacement.

System Description:
The complete weapon system includes the following major sub-systems:
—missile and gun fire control system
—a missile launching system
—naval guns
—missiles: Sea Sparrow RIM-7H or Aspide

The missile and gun fire control system consists of a dual channel radar (pulse and CW), an operator's control console, a gun fire control system and a missile fire control system.

The pulse radar with its displays and control panel is the Selenia Orion RTN 10X, whilst the continuous wave radar Sirio RTN 12X, has been specially designed and developed by Selenia for missile guidance by the target illumination (semi-active homing) system. The two antennas are mechanically co-located and mounted on a single pedestal. The gun fire control system can be either digital (Ferranti WSA-4) or analogue (Elsag NA-10), the missile fire control system, designed and developed by Selenia, has been physically and functionally integrated in the gun fire control system.

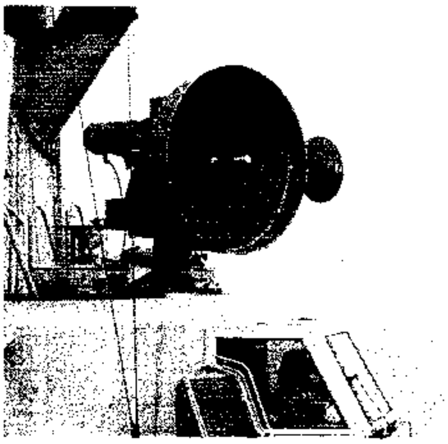
The missile launching system consists principally of an eight cell launcher capable of long term missile storage.

The mechanical parts of the launcher, the related power drives, the missile cell climatisation and the fire extinguishing unit have been designed and developed by Oto-Melara (**2247.293**), whilst the electrical and mechanical interfaces with the missile and the deck launcher control panel were designed and developed by Selenia.

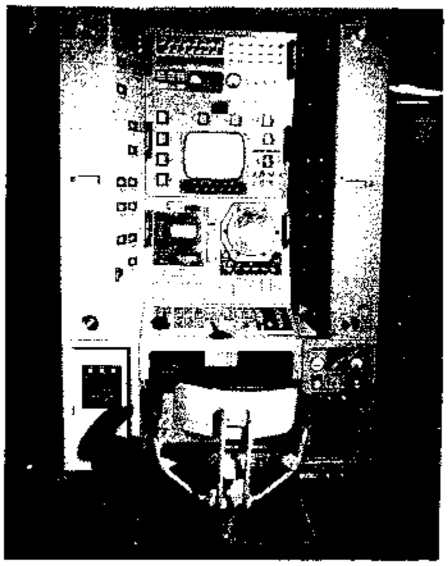
If the ship's operational role calls for more than eight missiles, they can be stored in a magazine close to the launcher and loaded into the cells by means of a semi-automatic system designed by Selenia.

The naval guns may be of any type. Three different groups of guns, even of two different ballistics can be controlled by the fire control system, not only in the anti-air and anti-ship role, but also for shore bombardment, illuminant firing and decoy dispensing.

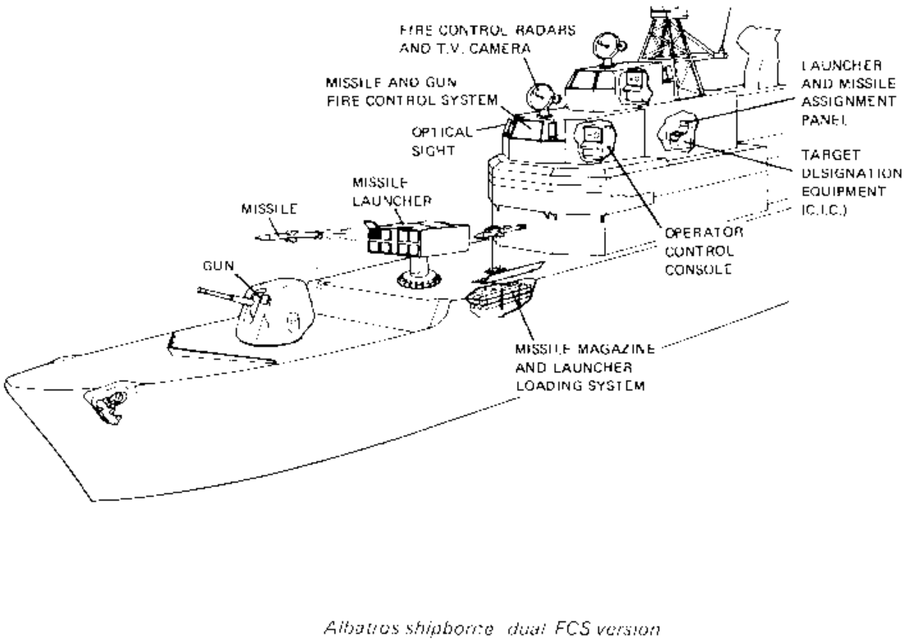
The missile used is the Sparrow III modified for the shipborne role by the use of folding wings and clipped tail and the addition of a rapid run up capability. This missile has been renamed Spar-



Albatros dual-channel tracking radar



Albatros Mod 3 Operator's control console



Albatros shipborne dual FCS version

row RIM-7-H (**1106.331**). A new missile, named Aspide (**1656.331**), now under development by Selenia under an Italian MOD contract, has been designed to be fully compatible with the Albatros system to which it will give improved performance.

The whole system can be checked by the use of built-in test equipment.

The Albatros system is offered in two basic configurations: Mod. 2, with the Ferranti WSA-4 gun fire control system (**1524.281**); Mod. 3, with the Elsag NA-10 gun fire control system (**1550.281**). Both use the Selenia tracking radar of the new Orion RTN 10X series. The system is available in two versions: with one or two fire control systems respectively, the latter having the ability to engage two targets simultaneously. The entire missile portion of the Albatros system is also available as a retrofit for integration with other gun fire control systems already installed on board.

Operation:

The functions performed by the Albatros system are:
- low elevation autonomous search and self acquisition;
- automatic and/or manual acquisition of designated targets;
- automatic target tracking and illumination;
- automatic target track shifting to anti-ship missile launched by a platform (aircraft or vessel) already being tracked;
- missile and launcher control;
- provision of firing data to guns.

Only one operator is required to carry out radar control functions, missile launches and gun fire control. One or two optical directors as well as a low light level TV equipment form part of the fire control system to provide the Albatros system with an auxiliary mode of search, tracking, target identification, engagement of targets in close formation, kill assessment etc. Either guns or missiles or both simultaneously can be used to engage a target and the system is designed to combine missile and gun capabilities so as to permit target engagement from maximum missile range (more than 15 km), down to minimum gun range (about 200 m). System reaction time is particularly low to counter sudden and multiple threats and the use of two radar channels, both capable of acquiring and tracking the target, enhances the system flexibility and the ECCM capabilities. The system's high kill probability permits the adoption of the shoot look-shoot firing doctrine in the majority of cases.

Development

The first feasibility and design studies were made by Selenia in late 1966. System development, under Italian MoD contract, started in early 1968. Selenia was responsible for the overall system design and coordination in development. Firing tests against guided air and surface targets were successfully conducted at the Salto di Quirra Sardinia, missile range, in July 1971.

Technical and operational evaluation firings were carried out in 1972 and 1973 by the Italian Navy with a prototype of the Albatros system installed on an operational ship. The evaluation was aimed to test the system in its natural environment and included launches against air and surface targets in situations which reproduced the most important operational conditions that the Albatros system was designed to meet.

Status

Systems are now being installed in ships of a number of navies, including the Italian Navy. The first systems are expected to be operational by the end of 1975.

M20 SERIES FIRE CONTROL SYSTEMS

Description:

The M20 Series comprises a range of integrated ships' fire control systems for use with guns, missiles and torpedoes, and designed for fitting in vessels ranging in size from fast patrol boats to destroyers. Principal applications are to medium/close-range air defence and close range surface defence. Simultaneous engagement of several targets is possible. A further use is for shore bombardment.

Computation and control is based upon a central digital computer, and the range of available sensors includes separate search and tracking radars, and optical trackers. The use of TV trackers is a further option.

One of the most notable features of this series is the advanced search and target tracking radar sub-system.

Separate radars are used for each function, but both are mounted on a common stabilised platform, with one radar on the upper surface and the other below. The whole assembly is housed in a weather proof radome. The stabilisation arrangements consist of a series of gimbal rings, with a common vertical axis about which the two radars rotate, passing through the centre of the two horizontal axes of the gimbals. The assumed method of operation is for the radar rotational axis mounting to carry suitable vertical sensing devices, the output of which is used to apply control signals to the two horizontal gimbal rings to maintain both horizontal under pitch and roll conditions. In this way the rotational axis of the radars is kept vertical and no other compensation need be applied to their respective elevation movements to correct for ship's motion.

Various combinations of two basic radar types (one of these appearing in two versions) are employed in several types of M20 series fire control systems which have been produced. The choice is principally governed by the weapons to be controlled by the system. The different radar combinations lead to the use of two basic radome configurations, one roughly spherical in shape, and the other more nearly hemi-spherical with a flat base.

Of the two main radar types one has a circular dish antenna which is apparently of the Cassegrain type. This is mounted in the upper position in systems where two radars are employed, and is for air search and target tracking. The other radar, mounted below the gimbal ring, has a paraboloid segment scanner illuminated by a horn feed. In two-radar systems, this sensor is suspended beneath its turning gear, while in single radar installations it is mounted above the stabilised mounting.

In the following paragraphs those details of specific M20 Series systems which have been obtained are listed.

M20:

This version has been designed as an integrated torpedo and gun weapon control system for use on small ships against air and surface targets. It can control two light or medium calibre guns against one air and one surface target either simultaneously or separately; or two torpedoes (wire-guided or free-running) against two targets simultaneously. The dual radar system provides for surface warning and tracking and air target tracking. One air target and three surface targets can be automatically tracked simultaneously. This can be accomplished in an ECM environment or adverse weather conditions. Digital computation is employed. Additional target data is available from an optical sight.

Separate display and operating consoles are provided for gun and torpedo control, respectively. Range scales on the former PPI presentation are 60, 30, or 10 km, and for the torpedo display 24, 12, or 6 nautical miles. True motion, relative motion, or off-centred display can be selected.

Installed system weight is approximately 3,300 kg, and the radar antenna assembly contributes 600 kg of this total.

M22:

This is a simpler version which is intended for use on larger vessels than the M20, such as frigates, in conjunction with long-range warning radars, or as an autonomous weapon system. It may also be integrated in an automated action information system. The operational function is the direction of two light or medium calibre guns against one air and one surface target simultaneously.

The dual radar configuration is employed, and helical or horizontal scan patterns can be used for the search mode, with monopulse tracking for air targets, and track-while-scan (PPI-autofollow) for surface targets. Display arrangements include PPI, A-scope, B-scope, and digital readout. Additional target data can be derived from an optional sight.

M25:

This system has been designed to control one semi-active homing missile, one surface-to-surface missile, and medium calibre guns. It is capable of tracking simultaneously either one air target and two surface targets, or one air target, one surface target and one shore target. The M25 system was designed especially for low-level air defence, and utilises the integrated system concept combined with anti-clutter and anti-jamming features to this end.

Facilities and functions of the system include: continuous air and surface surveillance; sensor data handling; data exchange with an action information system; display of tactical information; weapon control. The dual radar configuration is employed, with choice of search patterns and pulse doppler tracking of air targets and track-while-scan tracking of surface targets.

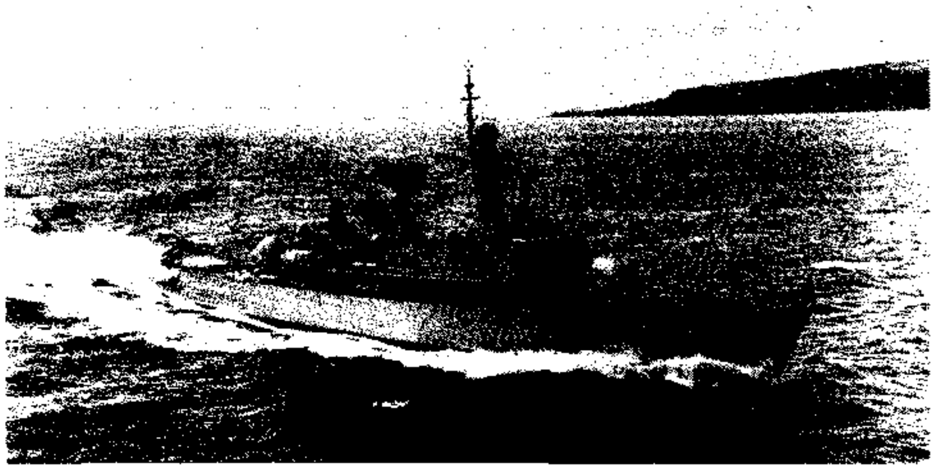
The X-band search radar has digital MTI and circular polarisation facilities and extensive ECCM provisions are incorporated as standard. Other sensors are a TV director and two optical target designation sights. The former sub-system has provisions for low light-level TV and infra-red target tracking. An SMR digital computer is employed and this is a micro-min, stored programme general purpose machine.

The M25 operates as a self-contained system on board small or medium-sized ships. On ships of destroyer size or larger, it can function as an autonomous weapon cell, backed by long-range air warning radar(s) and can be integrated into an automatic combat information system.

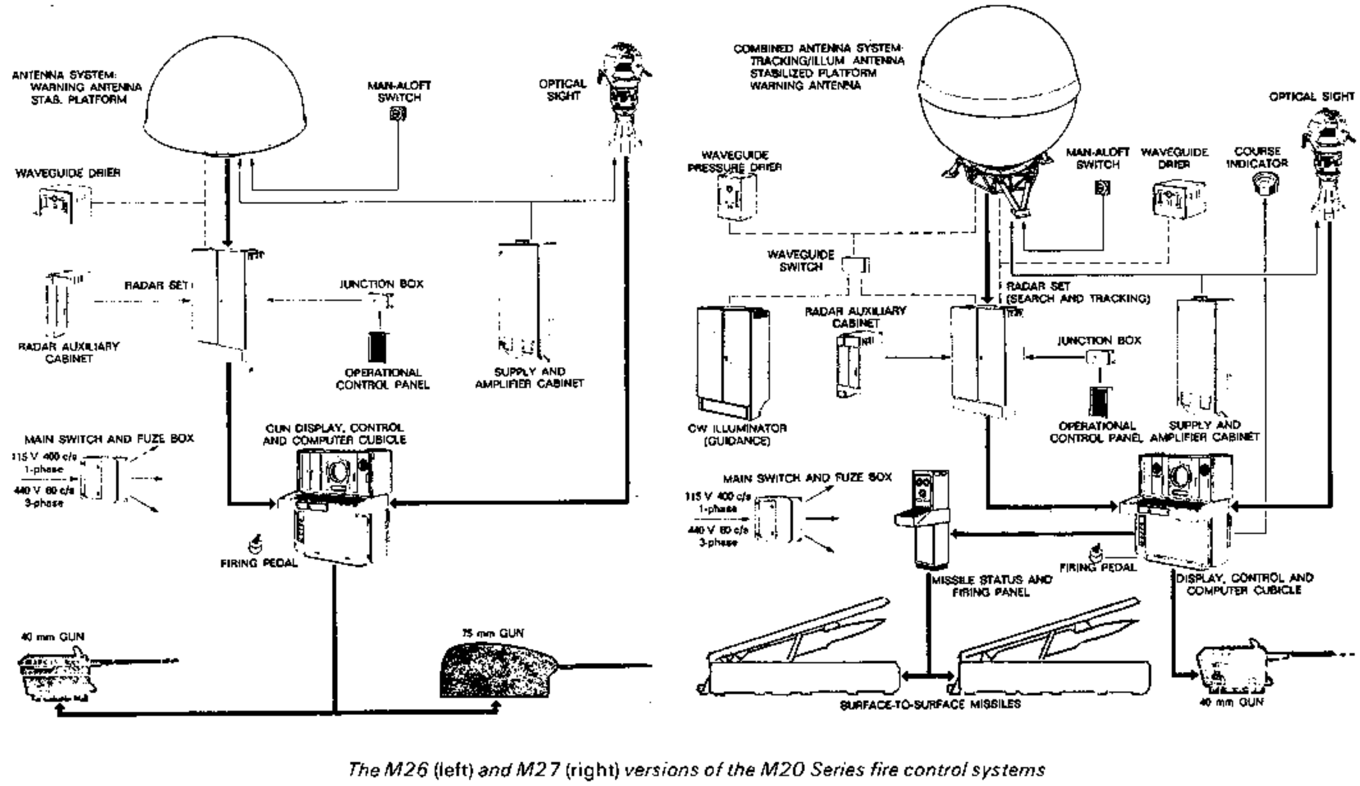
M26:

This system is designed as a gun weapon control and navigation system, providing for continuous air and surface warning, radar aid to navigation, combat information. Target indication to weapons, and weapon control. One gun can be controlled for surface action and target indications for a light AA gun under local control are also available.

A single radar system is provided giving search and track-while-scan facilities for one surface or shore target. The latter facility can be automatic or rate-aided. PPI, B-scope and digital readout dis-



The recently commissioned Royal Thai Navy Yarrow frigate HTMS Makut Rajakumarn. The M22 fire control radar is on the mainmast with the LW 04 search radar aft of it. Aft of funnel is M44 fire control radar



The M26 (left) and M27 (right) versions of the M20 Series fire control systems plays are provided. Radar data is supplemented by an optical sight. Installed weight is approximately 2,300 kg, of which the scanner assembly contributes 400 kg.

M27:

This version is designed as a weapon control system for surface-to-surface missiles and guns on board small vessels. Sensors employed are the dual radar installation and an optical sight. Weapons controlled are one light or medium calibre gun against an air or surface target, and one medium-range surface-to-surface missile of the semi-active homing type against a surface target. The two targets can be tracked automatically and simultaneously. For missile operation the air target tracking antenna is slaved to the surface target tracking programme and connected to a CW transmitter to provide target illumination. Weight and other details are similar to those for the M22.

M28:

The M28 system has been designed to control one surface-to-surface missile and two light or medium-calibre guns. The system can track one air and one surface target simultaneously. Engagement capabilities depend upon the post-launch control requirements of the missile employed. If the SSM need not be controlled after launch, the system can engage one air target with one gun and one surface target with either the other gun or the SSM. Alternatively, if the missile does require control after launch, the system can engage one surface target with one gun and another surface target with the SSM, or, one air and one surface target with one gun to each.

The dual radar configuration is used with horizontal or helical search patterns, monopulse tracking of air targets, and PPI-autofollow for surface targets.

An optical target designation sight is included. The system has its own digital computer and can be employed as a self-contained system on smaller ships or incorporated into more sophisticated automated combat information complexes on larger vessels.

STATUS:

Known M20 Series fittings, completed or projected, for various classes of ships of different navies include the following:

Argentina:

Two new construction fast patrol boats. The M20 FCS will control surface armament and will be associated with an M 11 torpedo FCS.

Australia:

"Daring" Class (twin installation) in *Vampire* and *Vendetta*; projected DDL destroyers; modernised "River" Class destroyers *Swan* and *Torrens*.

Belgium:

Four new construction *Westhinder* Class escort vessels.

Canada:

"Iroquois" Class missile destroyers (twin installation); support ship *Protecteur*.

Finland:

Corvettes *Karajla* and *Turunmaa*.

Germany—Federal Republic:

Type 143 fast missile boats; "Jaguar" Class fast patrol boats.

Malaysia:

Yarrow frigate *Rahmat*.

Netherlands:

Two new construction DDGs; "S"-Class frigates.

Nigeria:

Two Vosper Thornycroft Mk 3 corvettes.

Norway:

Five "Oslo" Class frigates; "Storm" Class fast patrol boats.

Singapore:

Three Type B Vosper Thornycroft fast patrol boats.

Sweden:

Two "Halland" Class destroyers; four "Visby" Class anti-submarine frigates; "Spica" Class torpedo boats.

Thailand:

Yarrow frigate *Makut Rajakumara*.

USA:

The M20 has been supplied to the USN for evaluation, and licence production arrangements have been made with Sperry Rand in the USA. The US designation is GFCS Mk 87.

MANUFACTURER:

N.V. Hollandse Signaalapparaten, Hengelo, Netherlands, PO Box 42.

ASWDS – ANTI-SUBMARINE WARFARE DATA SYSTEM

DESCRIPTION:

The ASWDS is a data handling and fire control system for anti-submarine warfare. It can be operated in conjunction with a ship's overall weapon and command system and the necessary functions of data coordination and presentation etc are handled by a Signaal SMR digital computer. The overall ASWDS functions include: collection, collation, processing, storage and display of tactical ASW information for the Command Team; distribution of data to various users; fire control of ASW weapons for selected targets.

Three sub-systems comprise the ASWDS:

(1) Computer Sub-system – consisting of an SMR computer and standard peripherals.

(2) Sensor Weapon Converter Sub-system – which interfaces weapons, sensors and processor, and includes the converter unit (located with the computer) and a number of remote control panels, such as those for weapon status and weapon control.

(3) Display Sub-system – this integrates the sonar system with the computer system. The display is directly linked with the computer and provides for the presentation of panoramic sonar data.

A sonar signal injector provides a shipboard training facility, able to record and play back real and injected simulated target signals, either mixed or not.

Types of weapons controlled include Asroc, anti-submarine mortars etc. In a typical ASWDS installation the computer and sensor weapon converter sub-systems will be housed in one equipment rack and separate digital type display consoles will be provided for primary and remote sonars.

DEVELOPMENT:

Development was initiated in 1967-68 in collaboration with the Royal Canadian Navy, which subsequently ordered a series of nine ASWDS for use in the DDE 259 and DDH 280 ship construction programmes. The systems for the latter class of ships are designated UDS-280, and further details will be found in Entries Nos. **2046.261** and **2047.261** earlier in this Section.

STATUS:

The ASWDS is in production and deliveries have commenced.

MANUFACTURER:

N.V. Hollandse Signaalapparaten, Hengelo, Netherlands, PO Box 42.

1663.261

CIDIS – COMBAT INFORMATION DISPLAY SYSTEM

DESCRIPTION:

CIDIS is a modular display system designed for use in ships' Combat Information Centres, where data from a number of external sources such as search radars, IFF, data link, has to be processed by digital computer and organised and presented for use by the Command Team. The normal computer is a Signaal SMR machine, but other types may be employed. The combination of CIDIS and digital computer produces DAISY, Digital Action Information System.

The equipment comprising a CIDIS installation consists of a Display Central Unit and a number of Display Consoles appropriate to the operational functions of the system. The former unit contains a sensor data distribution unit which acts as the interface between the various sensors and the displays, and a computer data distribution unit which interfaces the displays to the computer.

There are two types of display console, vertical and horizontal or 'conference' type. The former is produced in two versions, one for the presentation of radar video and for sonar data display; in each case the console has two indicators, a 40 cm labelled plan display and a smaller alpha-numeric 'tote' indicator. The horizontal display has a 40 cm labelled position display for radar data with two operator positions and a third supervisory position. An optional 'tote' display can be associated with each horizontal display for the presentation of supplementary alpha-numeric information.

Functions of the CIDIS include:

Display of raw video from ship's sensors on labelled position display (LPD).

Display of synthetic data from the computer in two forms: (1) as synthetic data consisting of symbols superimposed on raw radar video on the LPD, with or without track labels, at the operator's discretion. The operator can also select the category of information to be displayed, or (2) as alpha-numeric information on the 'tote' display.

Communication with the computer by means of control panels with push-buttons and a rolling ball.

STATUS:

Among ships fitted or to be fitted with systems of this type are improved "Leander" Class frigates for the Indian Navy, the Malaysian Yarrow frigate *Rahmat*, and a new construction Yarrow frigate for Thailand.

SEWACO – SENSOR, WEAPON AND COMMAND SYSTEM

DESCRIPTION:

Under the SEWACO designation Hollandse Signaalapparaten produces ships' action data automation and command and control systems of varying configurations, but mostly comprised of Signaal sensor, processing and display equipment. Four versions of the system are known to exist, SEWACO I which has been designed for the Royal Netherlands Navy's new guided missile frigate; SEWACO II for which no user has been spesified SEWACO III for the new S Class of Netherlands frigates; and SEWACO IV for the four new Belgian Westhinder Class of escorts which are now under construction. The principal differences relate to the sensors and weapons fitted in the classes of ship concerned.

The nucleus of the SEWACO system is a single digital computer which performs both combat information and weapon control functions, and which constitutes the DAISY-I command system. The following description of this part of the SEWACO complex refers specifically to SEWACO I but apart from a few detail differences the part played by DAISY in other SEWACO installations is broadly the same.

The hardware of the DAISY I command system, as well as the hardware of entailed software, was developed and produced by Hollandse Signaalapparaten in consultation with the RNethN, while the operational software of the system was developed and produced by the Centre of the Automation of Weapons and Command Systems of the RNethN. In addition to processing the sensor information and building-up a complete above and under water synthetic plot, this programme performs a number of technical functions, such as control of the 3D radar (SEWACO I only).

The DAISY-I command system offers direct and indirect interfaces with the sensors and weapons. Direct interface is by means of 24 bit input/output channels and indirect interface by means of digital-to-digital, analogue-to-digital and digital-to-analogue converters.

These capabilities have made it possible to insert into the SEWACO I system newly-developed computerised sub-systems as well as proven analogue systems.

In defining the system the aim was a configuration guaranteeing, at any time, a rapid and efficient counter attack with the ship's complete potential against above- and under-water threats, even with reduced manpower at quarters.

This design goal was achieved by rapid and, where possible, automatic collection of all the necessary data from sensors and automatic and non-automatic data links, and the processing and display of these data, threat evaluation and target designations to weapon systems.

The display sub-system comprises vertical labelled-position displays and tabular displays, grouped into double and triple indicator groups, as well as a horizontal conference display. The displays offer interlaced presentations of both raw radar pictures and synthetic information available from the computer memory. For its purpose, displays are fitted with the normal PPI viewing facilities together with communication links with the computer programme.

The operator can himself specify the quantity of synthetic information to be written on his display labels alongside the tracks give additional information such as track number and category; other additional information can include track history and bearing lines representing passive sensors and EW weapons. Tabular displays are used for specific tote pages providing supplementary information, computer recommendations and answers to problems posed by the operators.

Each display is multi-functional and, theoretically, can perform all operational tasks. In practice, however, each display has a special operational mode depending on the location of related special purpose panels, remote-control panels, etc.

SEWACO I:

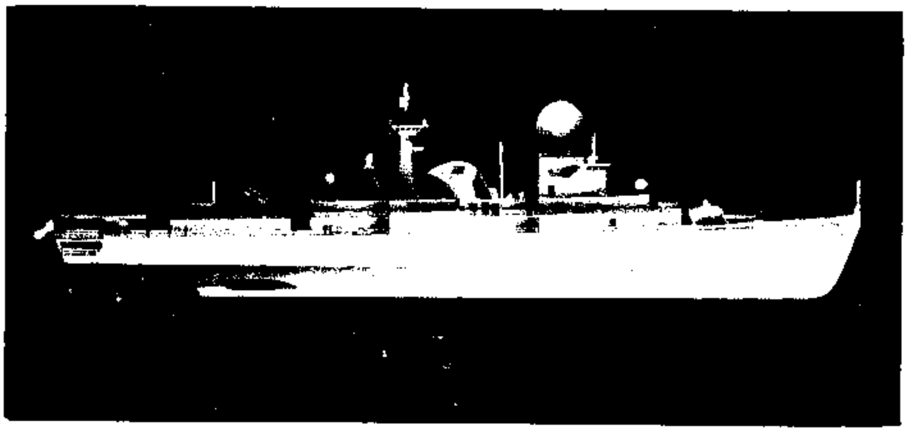
The principal sensors of the SEWACO I system in the new RNethN guided missile frigates will be the Signaal 3D multi-target tracking search and target designation radar (Entry No. **1589.253**) and the combined search and tracking radars of the WM 25 fire control system (Entry No. **1359.281**) which is integrated into SEWACO I. The 3D radar incorporates a slotted wave guide antenna for IFF/SIF facilities also. Navigation and helicopter control functions will be provided by a dual Decca Transar radar system, with port and starboard scanners to ensure gapless 360 deg coverage. There is also a secondary radar system as a further aid to helicopter operations. Long-range sonar is fitted. In addition the two SPG-51 fire control radar groups for the ship's Tartar surface-to-air missiles will also be linked with the system. Among the weapons associated with SEWACO I will be Tartar, the NATO Seasparrow point defence system and a twin 4.7 inch gun turret. At mid 1974 no decision had been reached on the choice of surface-to-surface missile, but the SEWACO I system has provision for the inclusion of such a weapon.

SEWACO II:

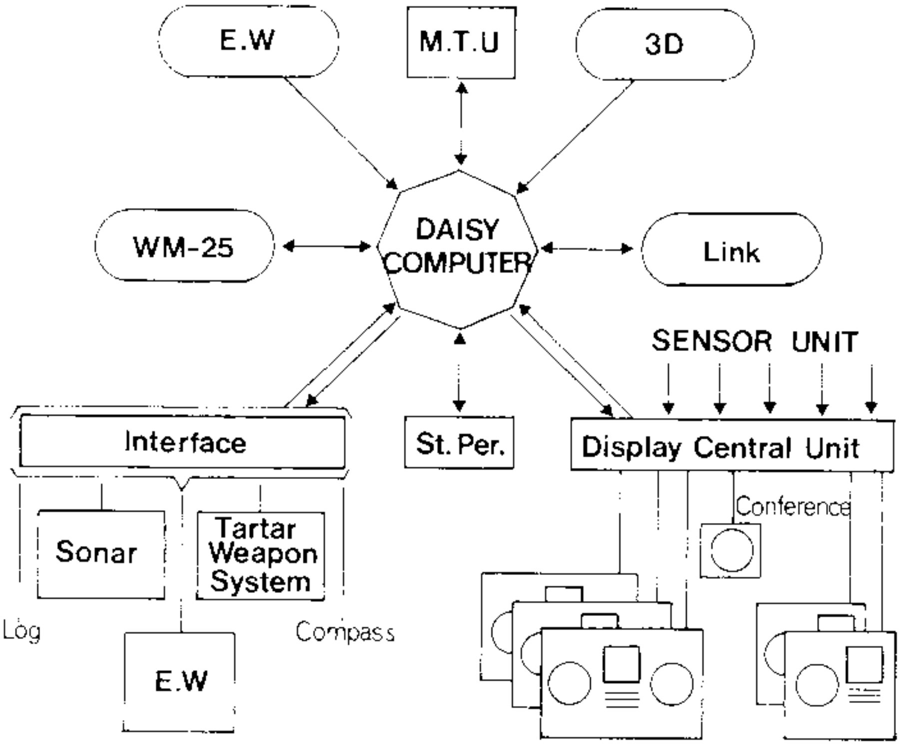
There are no details of the ship(s) for which SEWACO II is intended and it is possible that this designation refers to a system proposal by Hollandse Signaalapparaten. Sensors include Signaal ZW.06 and LW.08 radars, the combined search and tracking radars of a WM 25 fire control system forming part of the SEWACO system, a separate tracking illuminator radar, passive direction finding equipment, two optical target designation sights, a TV director, IFF, data link and the AN/SQS-505 sonar set. Weapons listed include guns, Exocet surface-to-surface missiles, NATO Seasparrow, and A/S weapons.

A total of twelve operator consoles are detailed, allocated to the following functions:

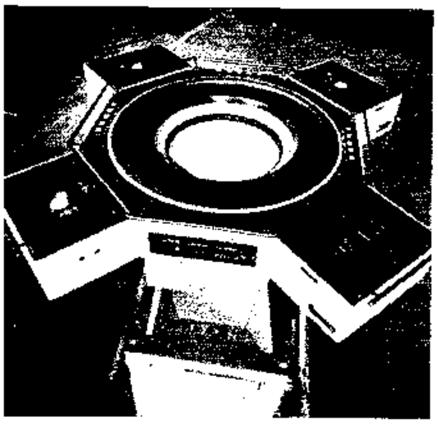
(1) Air situation display
(2) Surface situation display
(3) Electronic warfare and data link control
(4) Command and control
(5) Weapon direction
(6) Helicopter control
(7) Anti-submarine warfare
(8) Hull-mounted sonar
(9) Variable depth sonar
(10) Sonar Signal Injector
(11) Weapon control console
(12) TV console



Model of Royal Netherlands Navy guided weapon frigate equipped with SEWACO I system



Block diagram of DAISY-1 (Digital Action Information System) processing and display portion of SEWACO system



Typical conference type display console of SEWACO system. Three-position and single position displays also are used

This system has been described as being for installation in a frigate but the class and nationality have not been identified.

SEWACO III:

This designation has been allocated to the SEWACO system for the newly announced S-Type frigates for the RNethN. This class is thought likely to contain several variants for differing operational roles, and consequently weapons fits may differ. For this reason it is considered likely that the SEWACO III configuration has not yet been finalised. A typical weapon fit includes: surface-to-surface missiles, NATO Sea Sparrow, ASW torpedoes, OTO-Melara 76/62 Compact dual-purpose gun, and helicopter. The sensor complement could well be very similar to that of the new Belgian escorts which are to have SEWACO IV systems (see below)

SEWACO IV:

This is the designation of the SEWACO system being supplied for the new "Westhinder" Class of escorts under construction for the Belgian Navy. No official details have been revealed but the following data derived from published sources corresponds with what is known of these new vessels and their weapons and equipment fits. Functions of the SEWACO system include:

Air, surface and sub-surface warning;
Compilation and display of tactical air, surface and sub-surface situations;
Threat evaluation and automatic air target selection for engagement by the appropriate weapon system;
Weapon assignment and fire control by the WM 25 FCS against air, surface, sub-surface, and shore targets;
Anti-submarine warfare;
Electronic warfare;
Data link operation;
Assistance in tactical operations, including ASW-helicopter direction and navigation;
Target simulation for training purposes.

Sensors comprise a DA.05 air and surface warning and target indication radar, WM.25 combined search and tracking radars, a ZW.06 surface search/navigation/helicopter control radar, IFF/SIF, helicopter transponder, MEL Equipment Co. Ltd. SUSIE passive ECM system, data link, radar/optical director, and sonar. Weapons controlled by the SEWACO system include surface-to-air missiles, surface-to-surface missiles, dual-purpose gun, anti-submarine rocket launcher, ASW torpedoes, and ECM systems. The weapon control and combat information equipment consists of the WM.25 FCS for missiles, gun and A/S rockets, three horizontal displays for combat information functions and each with its own separate alpha-numeric 'tote' display, a sonar display console, radar plotting table with true-motion computer, and one video extractor for automatic air and surface tracking.

MANUFACTURER:

N.V. Hollandse Signaalapparaten, Hengelo, Netherlands, PO Box 42.

1261.281
M40 SERIES FIRE CONTROL SYSTEMS

DESCRIPTION:

The M40 Series of fire control systems comprises a range of combined radar and optical directors for the control of short-range missiles and gun fire against air and surface targets. Target designation is performed by one of the ship's other search radars. The 44M is used with the Seacat missile (which see) and the M45 is for the control of medium and light calibre guns.

STATUS:

M40 Series FCS have been fitted or specified for: the Netherlands "Van Speyk" class frigates; Indian "Leander" class frigates; the Malaysian frigate *Hang Jebat;* the Thai frigate *Makut Rajakumara;* Australian "River" class anti-submarine frigates.

MANUFACTURER:

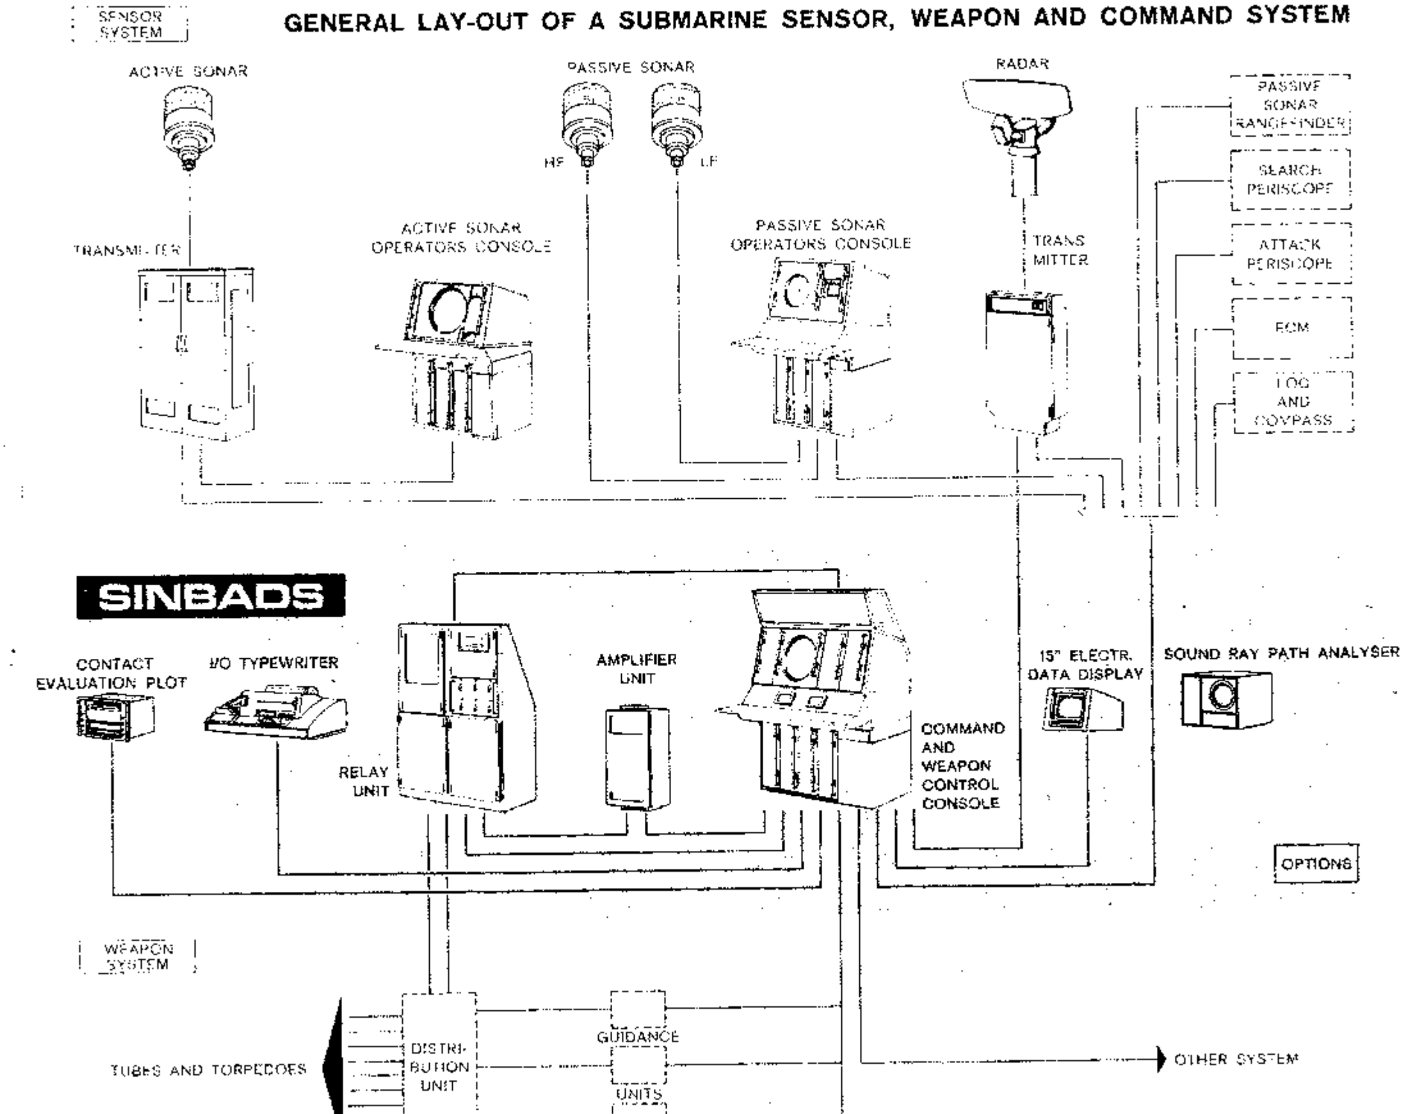
Hollandse Signaalapparaten, Hengelo, Netherlands, PO Box 42.

1662.481
SINBADS – SUBMARINE INTEGRATED BATTLE & DATA SYSTEM (M8/41)

DESCRIPTION:

SINBADS is a compact data handling and weapon control system suitable for use in submarines of the small coastal type and up to the larger, ocean-going type. It represents the latest stage of development of the HSA M8 Series of torpedo FCS (**1375.481**) and forms an integral part of a submarine's sensor, weapon and command system and it incorporates the display, computer and interface equipment. The computer used is the Signaal third-generation general purpose machine, SMR-S and the complete system combines the weapon control and data handling

GENERAL LAY-OUT OF A SUBMARINE SENSOR, WEAPON AND COMMAND SYSTEM



functions. Input data from sensors are collected, stored and processed for the calculation of target parameters, prediction and torpedo control. An important feature of the system philosophy is the processing of "bearings-only" information, derived from new generation fast-scanning pass ve sonars capable of multi-target tracking, such as the Van der Heem Electronics LWS-30.

The Tactical and Weapon Control Display is a 16-inch (40 cm) CRT which operates in two modes:

Mode 1. Plan Display, giving a geographical presentation of the tactical situation. This synthetic picture consists of symbols, alphanumeric characters, lines and dots. When using the submarine's radar, the radar video is presented together with the synthetic picture.

Mode 2: Time-Bearing Display; when only sonar bearings are available, the time bearing curves of a number of targets are presented, showing the target motion with respect to 'own ship' movement.

Complementary displays on the console include a target evaluation display, which is a graphical display used as a visual aid to determine the target parameters of one sonar target, and an electronic data display for the display of alphanumerics in tabular form for computer read-out and manual input.

OPERATION:

Principal operational facilities of SINBADS include:

Integration with a number of sensors, to accept and process all available information.

Simultaneous tracking of targets: five time-bearing tracks from passive sonar data, of which three targets can be selected for position tracking based on additional data from other sources.

Presentation of information for evaluation of the tactical situation and monitoring torpedo trajectory.

Prediction for weapon control, and simultaneous guidance of up to three wire-guided torpedoes.

Control of wire-guided, non-guided homing, programmed and straight-running torpedoes.

Comprehensive data recording.

Weapon simulation for training.

Navigation.

MANUFACTURER:

N.V. Hollandse Signaalapparaten, Hengelo, Netherlands. PO Box 42.

1375.481

M8 SUBMARINE TORPEDO FIRE CONTROL SYSTEM

DESCRIPTION:

The M8 is a digital computer based fire control system for use in submarines for the direction of torpedoes against either surface shipping or submerged targets. It is produced in several versions with designations ranging from the M8/0 of the mid-1950s prototype to the newest M8/41. The basic system comprises a torpedo display control and computer console; a sound path display unit; amplifier and supply unit; distribution box; local control panel(s); and gyro angle setting units. Complete system weight is about 900 kg. The system may be operated by one man, or two men if the submarine is operating with consorts.

The system will accept target data inputs from a range of sensors which includes radar, sonar, passive sound detection systems, periscope observation and consort reports. Ship's own navigational data is also fed into the M8 computer. The display, which has range scale settings for 20, 10 and 5 km, presents the positions of all contacts from all sensors, simultaneously. One or more sensors may be connected to the computer for torpedo engagement, and up to three targets may be attacked simultaneously. The computer is programmed to provide firing data for wire-guided, programmed, conventional and other types of torpedo, and performs automatic calculation of target position, course, and speed. The CRT display can give true motion, relative motion or off-centred presentation of the tactical situation.

DEVELOPMENT:

The M8 Series originated in a RNethN contract awarded in 1955 for the development of a torpedo FCS for the "Dolfijn" Class submarines. West German interest in the system gave additional impetus to subsequent development and led to the successful development of systems for use in both submarines and surface ships. Two types of torpedo were involved, the AEG Seal and Seeschlange, for use against surface vessels and submarines, respectively. This successful collaboration with the German industry continued and M8 Series systems are standard fitting on all submarines produced by Howaldswerke Deutsche Werft in Kiel. The ultimate development is the SINBADS system described in Entry No **1662.481**, but other related developments are the M9 systems in the West German "Köln" and "Thetis" Class vessels, and the M11 systems for two new Argentinian fast patrol boats.

STATUS

At mid-1974 a total of 85 M8 Series systems had been ordered of which nearly 70 were for submarine fittings in 11 navies. The following list is believed to accurately record the known installations.

Argentine	Type 209 (2)
Colombia:	Type 209 (2)
Denmark:	Narhvalen Class (2)
Germany (Fed Rep):	Wilhelm Bauer (1)
	Type 205 (11)
	Type 206 (18)
Greece:	Type 209 (4)
Israel:	Type 206 (2)
Netherlands	Dolfijn Class (2)
	Potvis Class (2)
	Zwaardvis Class (2)
Norway:	Modified Type 205 (15)
Peru	Type 209 (2)
Turkey:	Type 209 (2)
Venezuela	Type 209 (2)

TORCI TORPEDO FIRE CONTROL SYSTEM

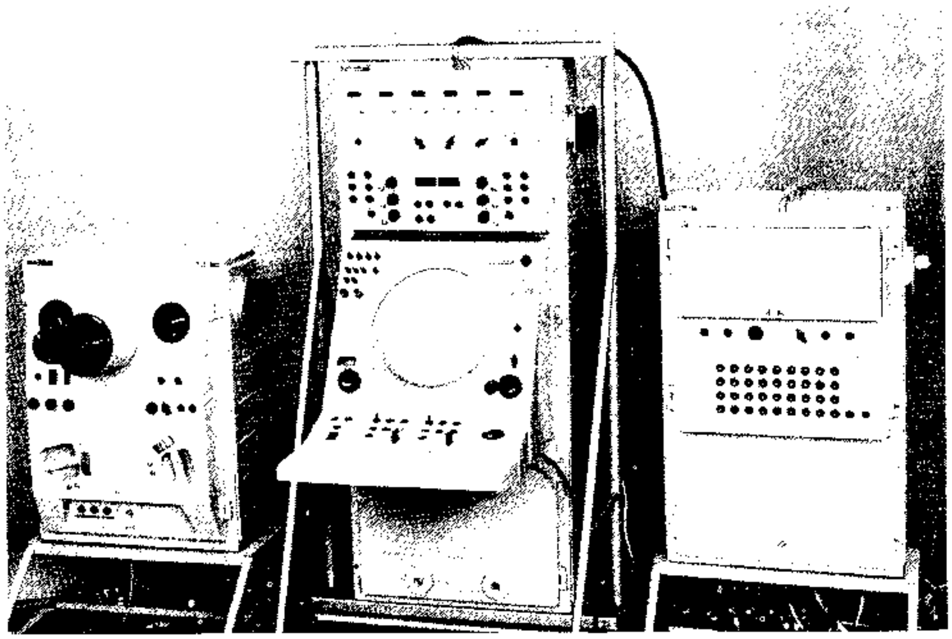
DESCRIPTION:

The TORCI torpedo fire control system is produced in several versions by Philips Teleindustri AB (PTAB) for the operation of guided torpedoes against surface targets from fast patrol boats. It is normally supplied with a PTAB X-band frequency-agile surface search radar, but is capable of use with other radars. The principal tactical functions of the system are

(1) Presentation of search radar information
(2) Presentation of the combat situation for the direction of surface engagements
(3) Rapid designation of surface targets
(4) Automatic or manual target tracking
(5) Guidance of two simultaneous torpedo salvoes.

The equipment comprises three units, the main display console, target tracker console, and an electronics/power supply unit. The last of these can be located remote from the two manned consoles. Modular construction with solid-state circuitry is used throughout and comprehensive self-test facilities are incorporated.

The main display console is provided with a PPI for the presentation of search radar data, synthetic symbols for tactical data, and relative or true motion presentation can be selected by the operator. The console also carries controls for operation



TORCI torpedo fire control system equipment. The main display console is in the centre, with the target tracker console on the left of the system and for target designation. The latter function is performed by means of a rolling ball which is used to position an electronic marker over the selected target on the main PPI display. Transfer to the target tracker is by operation of a push button. The main console also houses the torpedo computer and the programme selector.

Either manual or automatic target tracking is possible, and the torpedoes can be fired in salvo with chosen dispersion as well as one by one. One of two types of guidance can be selected. The controls and indicators for these functions are on the target tracker console. The electronics cabinet contains the co-ordinate converter and the necessary power supplies.

DEVELOPMENT:

The TORCI system has been developed from the RATSI system used on Swedish ships in the mid-1950s, and the first TORCI was delivered in 1959, since when it has been progressively improved.

STATUS:

Swedish vessels equipped with TORCI systems include the "Spica I" class of fast torpedo boats, in which TORCI is used with an HSA M22 radar/fire control system (Entry No. **1259.281**), and the new "Spica II" class. In the latter class, TORCI is used in conjunction with another PTAB fire control system, RAKEL, which provides for gun fire control against surface and air targets. A number of foreign navies also use TORCI.

MANUFACTURER:

Philips Teleindustri AB, Fack, 175 20, Järfälla-1, Sweden.

1542.281

9 LV 200 FIRE CONTROL SYSTEM

DESCRIPTION:

The 9 LV 200 has been developed as a fire control system for use on small ships, from 80 tonnes and upward, basically for the direction of dual-purpose guns (40-120 mm) but with provision for extension to other weapons such as anti-ship missiles (Exocet, Penguin, Otomat, etc) or torpedoes. In its basic form the system has the capability for directing one or several guns against one or more targets simultaneously.

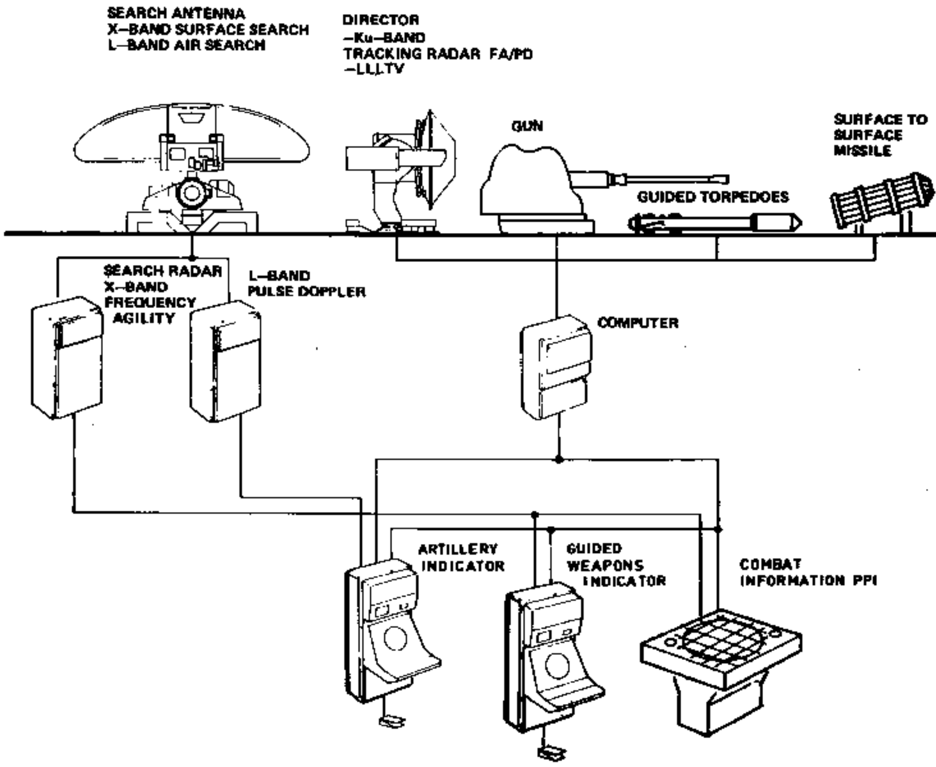
Target data is obtained from an X-band search radar and a Ku-band tracking radar, and there is provision for L-band air warning radar with IFF to be incorporated also. The X-band equipment in the 9 LV 200 is used for both search and tracking of surface targets and for air search. If the L-band, pulse-doppler radar is included, a combined antenna system for X-band, L-band and IFF Mk 10 is then used. The Ku-band tracking radar can also be modified with a separate pulse-doppler function to improve performance in adverse clutter conditions against small low-flying targets.

The search radar is of the frequency-agile type, incorporates comprehensive ECCM facilities, and is provided with a stabilised mounting. A helical scan pattern is used. The director radar is a monopulse equipment, with frequency agility, and the mounting also carries a TV camera.

Below deck equipment consists of the radar transmitter/receivers, computer, gun fire control console, and a combat information PPI. The gun console is equipped with a PPI for search, target designation and tactical situation functions, A-scope and TV monitor for tracking supervision, and tactical controls for director and gun functions. The guided weapons console has a B-scope for precision presentation of target data and tracking, a rolling ball for manual tracking, and tactical presentation and controls for guided weapons. The combat information PPI is of the 'conference' type and has full facilities for the display of search and tactical situation information, and controls for target designation to the weapon consoles.

Operational functions include:

- Simultaneous search for air and surface targets.
- Display of search radar data on the 40.6 cm combat information PPI with true motion presentation (surface), and on a 30.5 cm PPI in the main console with north-stabilised relative motion display (air).
- Rapid target allocation from search to tracking radar.
- Rapid changeover between targets.
- Automatic target acquisition and tracking of one air or surface target by the Ku-band radar.
- Manual or automatic tracking of one target by TV.
- Manual tracking of one target in range and bearing from search radar data displayed on a large B-scope (track-while-scan).
- Automatic computation of two target tracks to give independent control of gun and missile systems.
- Simultaneous engagement of one air and one surface target.
- Fall of shot observation by B-scope and/or TV and tracking radar A-scope.
- Use of TV and/or Ku-band radar in back-up mode.



9 LV 200 fire control system diagram

Examples of back-up operation include the use of the TV system to assist tracking of two air targets flying close together; tracking a very low-flying target giving radar multi-path problems due to sea returns; and making fall of shot observations. The Ku-band radar offers a back-up if the X-band unit is jammed or otherwise unusable.

DEVELOPMENT:

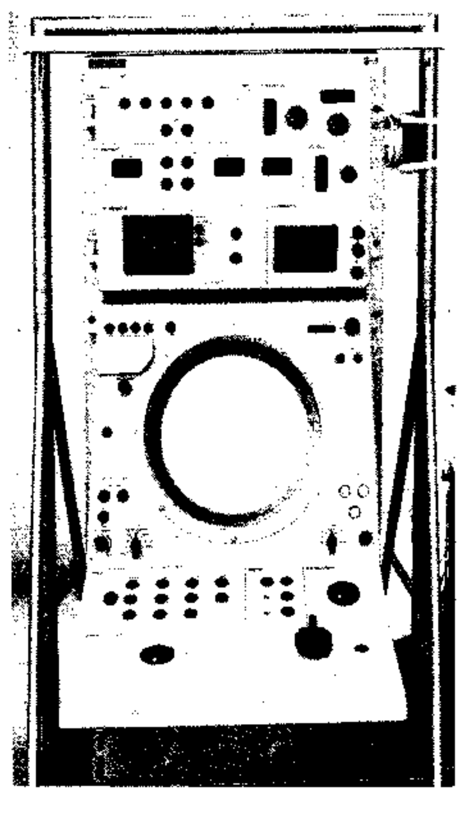
The 9 LV 200 is based on Philips Teleindustri AB long experience in naval fire control systems, and represents the most recent practice of this concern.

STATUS:

The first version of this system entered service in 1972. It has been specified by a number of foreign navies.

MANUFACTURER:

Philips Teleindustri AB, Fack, 175 20 Järfälla-1, Sweden.



Gun fire control console of 9 LV 200 system

1543.281
SEAFIRE WEAPON CONTROL SYSTEM

DESCRIPTION:

Seafire is an integrated weapon control system for motor gunboats armed with one or more surface to surface weapons such as, 75 or 40 mm guns, 57 mm flare rocket launcher, surface-to-surface missiles of the launch-and-leave type. Design objectives include, high resistance to jamming and mutual interference; a total system accuracy comparable to that of the weapon controlled, controls for firing preparations and ballistic correction shooting; rapid (tactical) change between three different ballistic programmes for the 75 mm gun.

Sensors for the system are a frequency-agile X-band radar and a periscopic sight. The former uses a helical scan pattern to provide both surface and air search functions. The periscopic sight is a 3 axis stabilised unit serving for both optical tracking and as a back-up to the radar for target designation. A television camera is an optional alternative sensor. A vertical gyro provides data to the system for stabilisation and computation purposes. All computations are referred to a north-oriented fixed-horizon co-ordinate system.

Indicators with large display screens and high resolution are used for the presentation of radar information, and displays are provided in the operations room and on the bridge. Evaluated target data (range, bearing, speed and course) are presented on easily read scales. The bridge PPI can be used for navigational use of the radar in addition to monitoring the tactical situation.

Tactical functions of the Seafire system are:

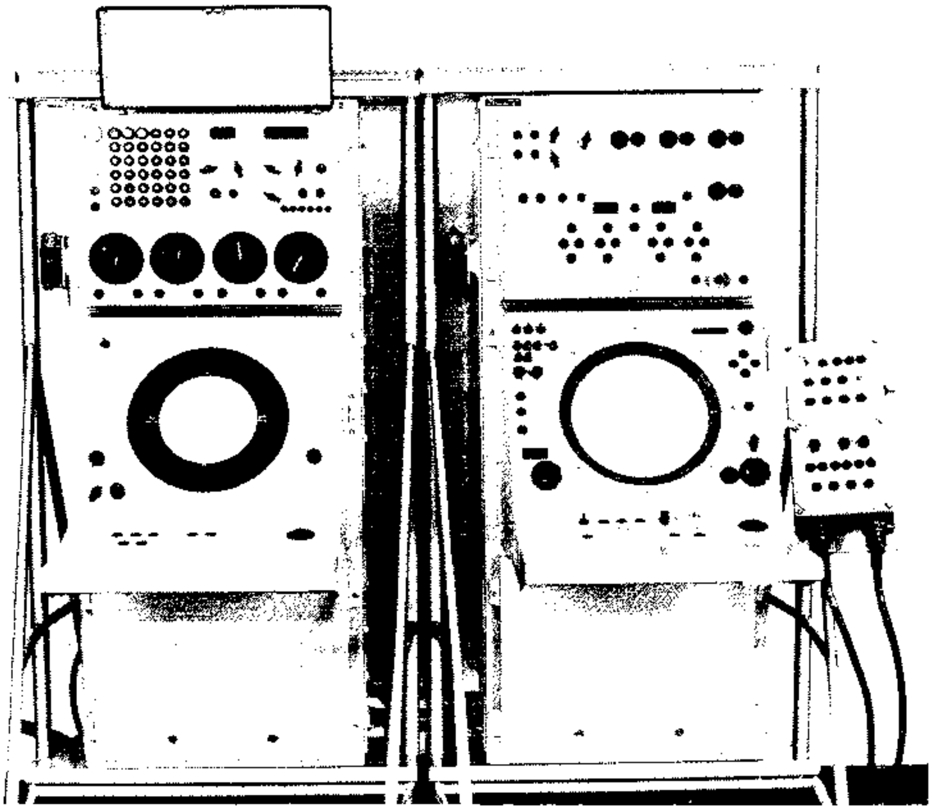
Continuous air and surface search.

Presentation of surface tactical situation and direction of surface action.

Indication of air and surface radar targets.

Continuous tracking by radar of one surface target, with quick target change facility.

Direction of lower-register fire with 75 mm gun at one surface target.



Philips Seafire weapon control system control consoles

Direction of coastal bombardment (direct or indirect) with 76 mm gun.

Fall-of-shot observation on B-scope.

Radar navigation.

Passive ECM-mode (direction finding) in X-band.

STATUS:

The Seafire system was at the advanced project stage in early 1972.

MANUFACTURER:

Philips Teleindustri AB, Fack, 175 20, Järfalla 1, Sweden.

1544.281
9 TCI 210 SUBMARINE TORPEDO FIRE CONTROL SYSTEM

DESCRIPTION

The 9 TCI 210 is a submarine torpedo fire control system for the detection, acquisition, tracking and engagement of surface targets by guided torpedoes. The principal sensor is normally the Philips 'Subfar' submarine radar (Entry No. **1545.453**). In addition to the radar, the other major items of equipment comprising the system are a tactical display unit, radar remote control unit, computer, sonar designation unit and plotting unit. These are all located in the Combat Information Centre (CIC). In the conning tower is a slave data display for the Captain's use and an antenna control unit. A torpedo control unit is housed in the torpedo compartment.

Operational facilities provided are:

Long range radar search against surface and low-level air targets.

Precision target acquisition and tracking.

Intermittent acquisition or continuous tracking.

Simultaneous engagement of two targets.

Tactical situation presentation.

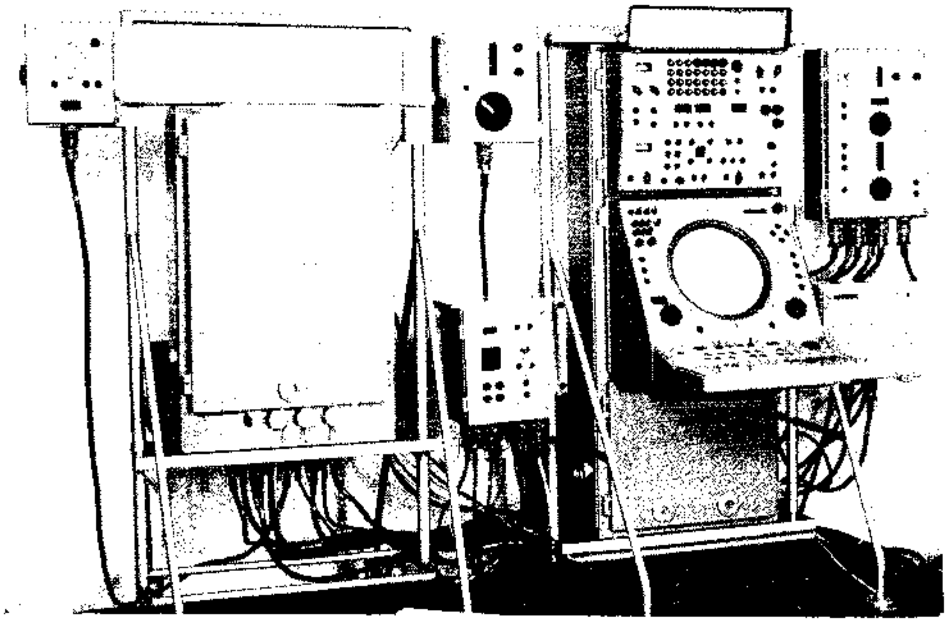
Target designation (range and bearing) to sonars or periscope.

Presentation of target bearing for plotting.

Captain's display.

Firing and automatic guidance of one to four torpedoes in the same attack, or firing of one to four pre set angle torpedoes.

Radar navigation.



9 TCI 210 Submarine torpedo fire control system equipment

DEVELOPMENT

The 9 TCI 210 system has been developed from the TCI 101 system of the 1950s.

STATUS:

In production. Philips TCI systems equip submarines of the Royal Swedish Navy and other navies.

MANUFACTURER

Philips Teleindustri AB, Fack, 175 20 Järfälla 1, Sweden.

SWITZERLAND

1552.281
SEA HUNTER-4 FIRE CONTROL SYSTEM

Based on the experience gained from production of more than 2.000 fire control systems for land- and ship-borne use and the results of extensive research work, Contraves A.G. Zurich developed a new generation naval fire control system designated Sea Hunter-4.

DESCRIPTION:

The system is designed for fitting in small to medium-sized surface vessels in conjunction with guns and missiles. Among the weapons controlled are

- guns ranging from 30 mm to 5 inch
- the Sea Killer Mk 2 ship-to-ship missile in deck fixed or trainable launcher mountings
- the Seacat ship-to-air missile

Other weapons can be accommodated, such as the Exocet ship-to-ship and the Sea Indigo ship-to-air missiles. Besides air defence and surface actions the system also provides for shore bombardment. Several targets can be engaged simultaneously.

One of the most notable features is the advanced target search and tracking capability. Two independent high power radars and a low light-level television system are used for these functions. The track and search antennae as well as the television camera are mounted on a common gyro-stabilised platform.

Targets can be acquired either with the search radar or with the track radar operating in an automatic helical search programme, or with other radars available in the ship, such as navigation and early warning radars. To this effect the picture of such external radars can be presented on the Sea Hunter PPI. The system also accepts target designations from optical sights and from a central tactical designation unit.

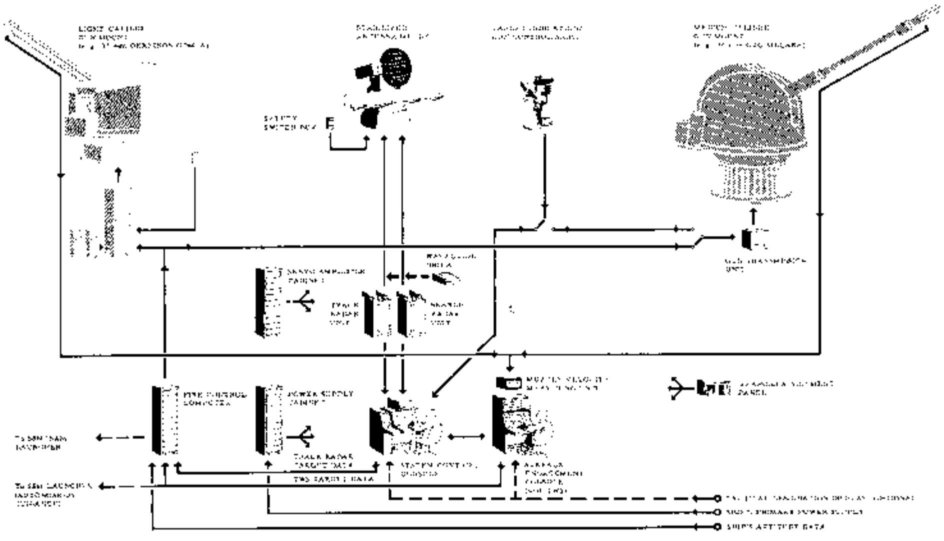
The television is of particular importance as a supplement to the track radar to assist in tracking of very low altitude airborne targets where radar becomes uncertain. It provides additional benefits in connection with shore bombardment, target acquisition, identification and kill assessment. It operates in lighting level conditions down to about quarter moon.

Assignment of the available weapons to the different fire control channels is selected at the weapon assignment panel. This is done by means of push buttons which are arranged and illuminated internally to show the combination of assignment in force. The state of operation of each weapon is indicated on the weapon assignment panel. Also on this panel is an open fire push for each weapon giving the Weapon Officer overriding control of the firing circuits.

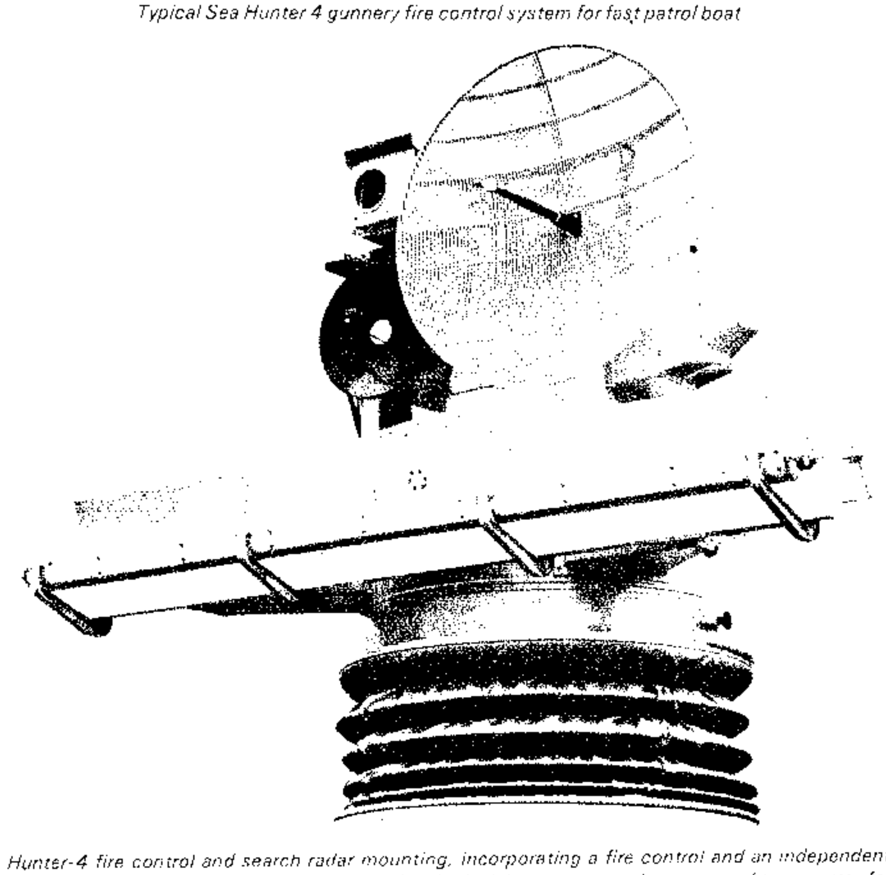
When a target has been acquired, prediction and aiming of the linked weapons are automatic, only the firing controls need to be operated. To assist in firing the weapons to best effect, "within range" lamps indicate when the predicted impact point is within the firing range of the weapons. The time required for target acquisition and computer setting is very short, thus a considerable amount of spare time is available between decision taking to acquire a target and opening of accurate fire.

All system units use solid state and miniaturised electronic components. The compact and lightweight design makes the system particularly suitable for installation in small vessels.

A typical Sea Hunter-4 gunnery system for fast patrol craft comprising a light and a medium calibre gun mounting is shown in the block diagram. The system allows simultaneous automatic controlled fire against two targets. Target number 1 can be an air, surface or shore target engaged by the system control operator with the track radar and/or television. Target number 2 is a surface target engaged by the operator at the surface engagement console in the "track while scan" mode, using the search radar. In emergency the medium calibre mounting can also be fired with the target indication/gun control sight in remote control.



Typical Sea Hunter 4 gunnery fire control system for fast patrol boat



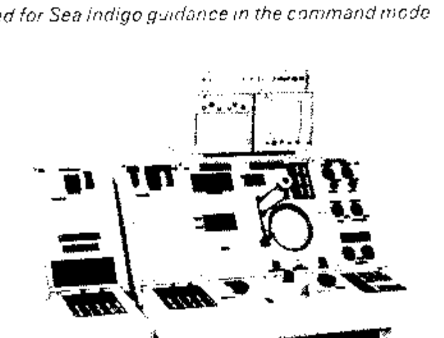
Sea Hunter-4 fire control and search radar mounting, incorporating a fire control and an independent search radar antenna, together with a low light level television camera and a command transmitter for missile guidance. An infra-red sensor can also be added for Sea Indigo guidance in the command mode

For the addition of missiles to the gun fighting power, launcher control data can be provided as indicated in the block diagram. These are either derived from track radar data or from the automatic track-while-scan prediction system, depending on the type of missile. Readily available complementary equipment for missile integration with the system includes all necessary launching and guidance units for the Sea Killer Mk 2 sea skimming SSM and a Seacat dark fire control console.

As a member of the Oerlikon-Bührle group of companies, Contraves are in a position to supply the Sea Hunter-4 fire control system together with the weapons, such as the Oerlikon 35 mm and the Hispano-Oerlikon 30 mm twin naval guns, assuming full responsibility for the entire weapon system package.

STATUS

Designed and developed as a private venture by Contraves A.G., Zurich, Switzerland, in collaboration with Contraves Italiana SpA, Rome, Italy. The first 10 systems went into service with different Navies in the years 1970 to 1972.



Sea Hunter-4 control console for engagement of air, surface, and shore targets

THE UNITED KINGDOM

1242.281
MRS3/GWS22 FIRE CONTROL SYSTEMS

DESCRIPTION:

Shipborne fire control system for the direction of gunfire against surface and aircraft targets, and the Seacat missile against aircraft targets. The MRS3 is designed for the control of RN guns of 3, 4.5 and 6 inch calibre. The GWS22 is designed to control the Seacat launcher and to provide guidance for the Seacat missile.

Each system is designed to work in conjunction with a ship's weapon direction system, the latter normally performing the target designation function. Radar or optical target acquisition and tracking methods are available. The radar provides auto-tracking facilities and guidance for Seacat missiles. Computation is performed by analogue methods.

DEVELOPMENT:

Design studies began in 1948 to devise a system to meet British Admiralty requirements.

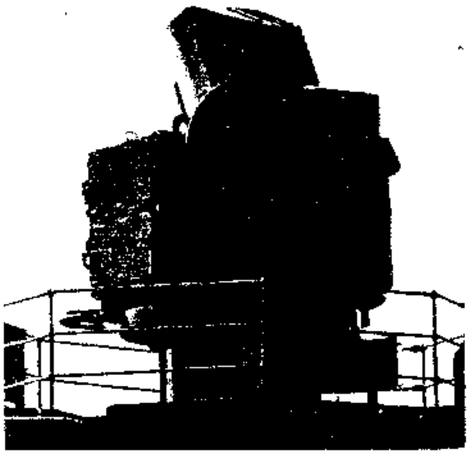
STATUS:

The MRS3 first entered service in 1958, followed by GWS22 in 1962, and now equips vessels of the 'Tiger', 'County', 'Rothesay', 'Tribal' and 'Leander' Classes of the Royal Navy, in addition to Commonwealth and other Navies. Over 100 have been supplied. In September 1973 it was revealed that Sperry had been awarded a multi-million pound contract for the up-dating and modernisation of RN MRS3 gunfire and GWS22 missile control systems. The modifications will up-date the director and tracking system for RN service for a number of years, and they include provision for a new Sperry designed gyro unit using gas bearings.

DESIGNED AND MANUFACTURED BY:

Sperry Gyroscope, Bracknell, Berks, England.

In accordance with British Admiralty policy, manufacture is decentralised and a number of other sources participated. These include Vickers Armstrong (Engineering) Ltd, GEC-AEI Electronics and Lawrence Scott who produce the surface predictor.



MRS3 fire control unit with radar and optical target acquisition and tracking facilities

1524.281
WSA-400 SERIES NAVAL WEAPON CONTROL SYSTEMS

DESCRIPTION

Derivatives of the RN Type 21 frigate Weapon Automation System 4, WSA-4 (**1496.281**) intended for other classes of vessel carry designations in the WSA-400 Series. There is considerable commonality of both hardware and software between WSA-4 and the WSA-400 Series versions, the principal differences being those necessary to accommodate varying combinations of sensor equipment and the weapon systems fitted for specific operational roles.

Three versions of the WSA-400 Series are to be fitted in the Vosper Thornycroft Type 10 frigates to be built for the Brazilian Navy, and which will form the 'Niteroi' Class. These ships will be completed in two types: one specialised anti-submarine type, whose armament will include Ikara missiles, and a general-purpose type to be fitted with Exocet surface-to-surface missiles. In addition, both types will carry Seacat air-to-surface missiles, 4.5 inch (114 mm) Mark 8 guns, anti-submarine weapons, and a torpedo armed helicopter.

Each type of vessel will be equipped with three digital systems based on Ferranti FM 1600B computers, and comprising one tactical and display system, and two fire control systems.

The first of these is a development of the Computer Assisted Action Information System (CAAIS), also being fitted to a number of RN ships, and in the case of the Brazilian vessels, designated CAAIS-400. This system will have six Decca CA 1600 two-man display consoles for the presentation of combined radar and computer generated data.

Both types of 'Niteroi' Class ships will have a WSA-401 as the Forward fire control system, principally for the control of the Mk 8 gun and also for a Bofors anti-submarine rocket launcher. The main sensor for this system will be the forward Selenia RTN-10X Orion tracker radar, with the ship's search radar providing target indication.

In the anti-submarine version of the Type 10 frigate, the After fire control system will be a WSA-402 which will have as its main weapon system the Ikara anti-submarine missile. The WSA-402 will have its own RTN-10X Orion fire control radar.

The general-purpose Type 10 after fire control system is a WSA-403 for the control of the second Mk 8 gun which is fitted in this class, and for Seacat missile control. The main sensor is an RTN-10X Orion fire control radar. All three Ferranti systems are interconnected to permit transfer of data between them in digital form to provide maximum operational flexibility and a high degree of freedom to transfer the functions of control positions, sensors and weapons to meet changing circumstances.

The systems for the Brazilian "Niteroi" Class frigates are similar to that being produced for the RN Type 21 ships. More details of "Niteroi" Class weapons and sensors are given in Entry No. **1665.281** at the beginning of this section.

DEVELOPMENT:

Tenders for the Type 10 frigates were invited in February 1970 and Ferranti prepared a total of twelve different system configurations. The systems evolved for the Vosper Thorneycroft frigate designs were selected, and these have subsequently been refined in collaboration with the Brazilian authorities.

STATUS

The Brazilian contract announced in September 1970 calls for six Type 10 frigates, four of which will be for anti-submarine duties. The first deliveries are expected to be made in the mid-1970s, and production of the WSA-400 Series equipment will match this schedule. There is a possibility that the 'Niteroi' Class may be extended to a total of ten vessels.

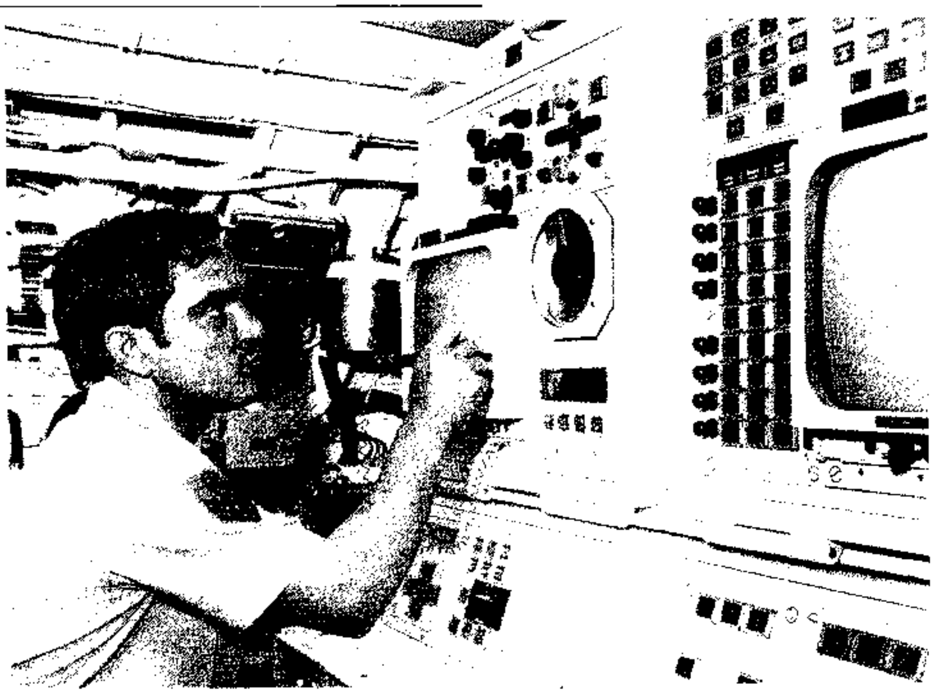
1233.481
TIOS – TACTICAL INFORMATION ORGANISATION SYSTEM

DESCRIPTION

TIOS is a computer-based tactical information system, developed initially by Vickers and ordered by the Brazilian Government for installation in its 'Oberon' Class submarines. It is capable of performing all the torpedo control functions of earlier



TIOS operating console installed aboard a modern submarine systems appropriate to vessels of this kind, and also provides additional facilities for the processing of tactical data, plus an extensive and flexible display system. Another major design feature is the use, in combination, of mostly extant equipment to yield a system only marginally more costly than its predecessors. It is suitable for retro-fit or new installation and is not limited to any particular class of submarine.

Capable of controlling all types of RN torpedoes TIOS, because of its modular construction, can be modified for the control of other torpedoes with minimal system changes. Wire guided, cable set, and spindle set types can be operated, specific types include the Mk 8 Mod 2/3/4, Mk 20, Mk 23 Mod 2/3, Mk 24 Mod 0, and Mk 37 Mod 0/1/2. Control of air-flight weapons, the Vickers SLAM (Submarine Launched Air Missile) system in particular, is under development. A further advantage over earlier equipment is the ability to control two guided torpedoes independently to permit simultaneous attacks.

The system displays tactical situations and provides full information on the operational state of the submarine. It may also be used for navigational purposes.

The console contains two 28 cm CRT displays, and five types of display information can be selected by the operator without affecting the computations being carried out. Display parameters can be changed manually by use of a light pen. A centralised tactical picture can thus be obtained. All tube ordering, weapon selection and system monitoring is performed at the console.

The digital computer employed is a Ferranti FM1600B, which has been standardised by the RN for fire control and other applications, and this stores all relevant information such as target positions, speeds, bearings, etc.

The interface between operator, computer and weapon (torpedoes, or SLAM) is the responsibility of Gresham Lion Electronics Ltd, and consists of a console providing facilities for CRT display of tactical data, manual or automatic guidance and computer input/output functions. Also on offer is an interface and computer programme for use with navigation systems such as Omega, to add to the inherent features of the system.

DEVELOPMENT:

The development of TIOS was a joint venture by Vickers, Ferranti and Gresham Lion. Further development of the fore-end equipment associated with TIOS has produced a compact fire control system that is well suited to submarines much smaller than the 'Oberon' Class. Factory acceptance of trials of the new equipment began in 1974.

STATUS:

The first system entered production in early 1970 and factory trials were completed in 1971. The first production system was installed during construction of a submarine for the Brazilian Navy in 1972 and underwent seagoing trials in February 1973. A permanent shore-based installation is in operation at Barrow-in-Furness for post-design development and training. Current developments for the shore facility include a programmable training aid to improve operator training by dynamic simulation of target manoeuvres.

MANUFACTURERS:

Vickers Ltd, Barrow Shipbuilding Works, PO Box 6, Barrow-in-Furness, England.

Ferranti Ltd, Digital Systems Dept, Western Road, Bracknell, Berks, RG12 1RA, England.

Gresham Lion Electronics Ltd, Twickenham Road, Hanworth, Middlesex, England.

1826.481
CICAS – COMPUTER INTEGRATED COMMAND AND ATTACK SYSTEM

DESCRIPTION:

The Computer Integrated Command and Attack System (CICAS) is the export version of a new system for submarine applications which is under development for the Royal Navy by Gresham Lion Electronics. Most information concerning this system is still classified, but it is known that CICAS and its RN counterpart are digital installations based on a Ferranti processor complex. It has been reported as being more advanced than TIOS, in which Gresham Lion is involved, and as using techniques not previously applied to warship systems to achieve close integration of the functions of Action Information Organisation and weapon control.

The feasibility study for RN CICAS was carried out in 1970 and the first production equipment had begun on site tests by early 1974. RN production orders have been placed and overseas interest is reported.

Modular techniques are employed and the system provides multi-target handling capability, and, in addition, control of a wide range of weapons that includes underwater-to-surface guided missiles being developed for the RN. The range of weapon control is variable by operator demand and can be changed at short notice. Elements of the system can, if required, duplicate the functions of other units without degradation of their own function. For example, attack displays may be used to present Action Information Organisation data and control facilities. In addition to the FM1600B computers employed for AIO and fire control data processing, other Ferranti equipment includes core storage modules, input/output devices and special-purpose interfaces. Ferranti engineers were also responsible for the software development. Display units for CICAS have been specially produced by Decca Radar.

MANUFACTURER:

Gresham Lion Electronics Ltd, Defence Division, Twickenham Road, Hanworth, Middlesex, England.

1827.481
TCS 9 TORPEDO CONTROL SYSTEM

DESCRIPTION:

This is a standard torpedo fire control system for certain Royal Navy submarines and it is also employed by a number of other navies. All details of the TCS 9 remain classified, however, apart from the information that it was preceded by TCS 6 and 7 equipments and TCS 9 itself has been the subject of more or less continuous development and modernisation. The Torpedo Guidance Control Unit Mk 2, which forms part of TCS 9 is produced by Gresham Lion Electronics, which company is now the design authority for the whole of the system as well as being responsible for repair and refurbishing on behalf of the RN.

1043.261
ADAWS Mk 1 – ACTION DATA AUTOMATION WEAPON SYSTEM FOR COUNTY CLASS GMDs

DESCRIPTION:

Shipborne automatic data-handling and display system, based on two Ferranti Poseidon digital computers which form the central processing complex.

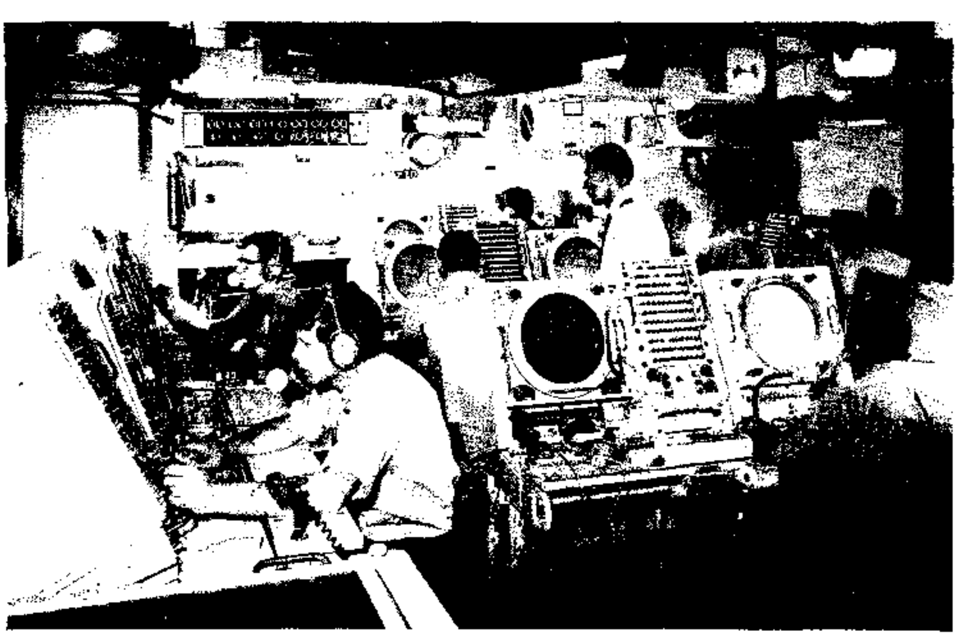
OPERATION:

The system provides for the automatic compilation of the air, surface and sub-surface tactical situation 'picture', using information from the ship's radars, sonars, passive direction finding equipment, and data link. The latter data source can be assumed to carry data from similar sensors deployed by co-operating craft of a force, such as ASW helicopters, and other surface vessels.

Automatic processing of surveillance radar and automatic operation of the height-finder radar is also incorporated. Target recommendations and target designation signals are provided for the ship's above-water weapons, such as Seaslug, Seacat and guns. These, however, retain their separate analogue fire control systems. Special functions are performed by the ADAWS system to enable optimal use to be made of the Seaslug II missile system. Orders are also calculated and displayed for fighter and helicopter action.

DEVELOPMENT:

Development work on the Poseidon computers began in 1959 based upon previous ADA system



The operations room of an ADAWS Mk 1 equipped guided missile destroyer

ies, first entering service in HMS *Eagle* in 63. The computers were designed and developed, the software written and ADAWS-1 developed by Ferranti working in collaboration with the

Admiralty Surface Weapons Establishment.

STATUS:
ADAWS Mk 1 entered service in 1965 on vessels of the 'County' class series of guided missile destroyers (Fife, Glamorgan, Antrim and Norfolk). A later version has now succeeded the Mk 1 system.

MANUFACTURERS:
Ferranti Ltd, Digital Systems Department, Western Road, Bracknell, Berks, RG12 1RA, England – all digital equipment.
Pye Ltd, Cambridge, Cambs, England – display consoles.

ADDITIONAL EQUIPMENT:
A shore trainer for the ADAWS Mk 1 was installed by Ferranti in 1969.

The "County" Class guided missile destroyer HMS Glamorgan

1044.261

ADAWS 2 ACTION DATA AUTOMATION WEAPONS SYSTEM

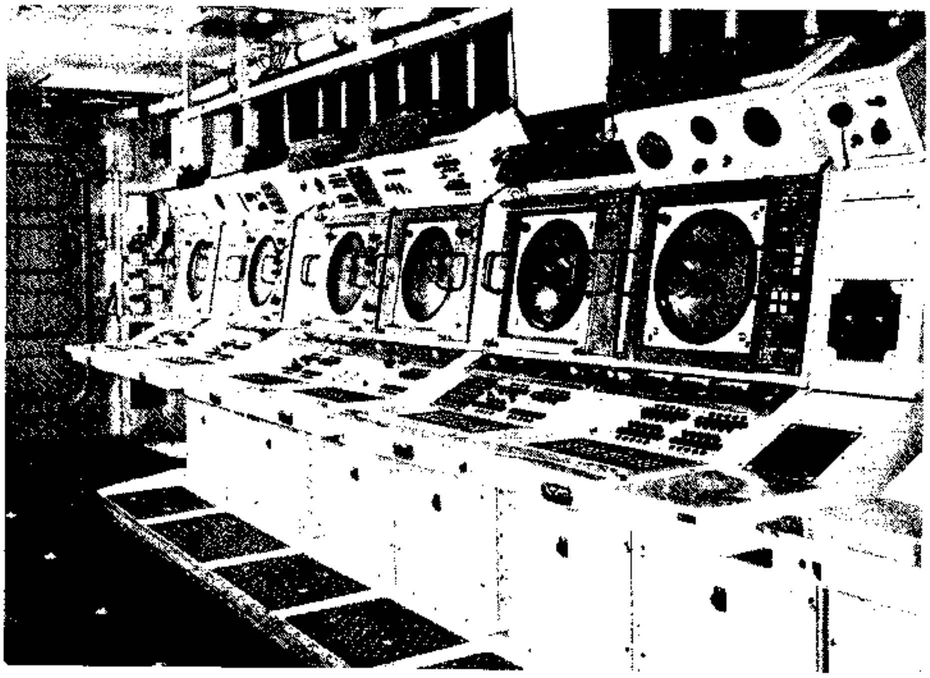
DESCRIPTION:
This is the first of a new series of action data automation systems developed for the Royal Navy and based upon Ferranti FM1600 series digital computers, and using later display equipment by Plessey to provide improved performance and facilities over those of the ADAWS Mk 1 which used Poseidon computers. Another important operational difference is that the later systems in addition to the action data automation functions, also provide fire control facilities for the various weapons carried by the vessel.

The ADAWS 2 has been designed for the Type 82 guided missile destroyer HMS *Bristol*, and accepts inputs from multiple sensors including radars, sonar, passive devices, and data link. The FM1600 micro-circuit computer suite performs the co-ordination, processing, distribution and display of tactical information derived from these sources. Fire control calculations and co-ordination are also performed by the computers for the armament of Sea Dart surface-to-air missiles, the Ikara ASW weapon, and conventional weapons fitted.

In comparison with the earlier ADA systems, still more comprehensive processing is performed on sensor data, and the Plessey Mk 8 digital autonomous displays provide improved facilities for the presentation of operational data. Integrated circuits are employed throughout the construction of these displays.

The ADAWS 2 display system comprises a number of labelled plan displays (LPD) and electronic data displays (totes) which operate in conjunction with a display central equipment. The display fit provides a comprehensive operations room outfit with a standardised type of display console incorporating a 305 mm CRT. This console is used for all purposes – picture compilation, tactical appreciation, and weapon control.

A new type of automated, three-man tactical display embodying a 560 mm CRT is a feature of these display systems, and this has been designed as a modern solid-state replacement for the traditional projection type plotting table. It provides access to all radar data and synthetic information available to the system, so that users can select the filtered data appropriate to the tactical situation. Comprehensive facilities are provided for readout of alpha/numeric data at the tactical displays and elsewhere in the operations room.



Plessey Mk 8 displays for ADAWS-2 on board HMS Bristol

DEVELOPMENT:
Development began in the mid-1960s, collaborating agencies being Ferranti, Plessey, Admiralty Surface Weapons Establishment, Admiralty Underwater Weapons Establishment.

STATUS:
The ADAWS 2 equipment for HMS *Bristol* was installed in 1970.

MANUFACTURERS:
Ferranti Ltd, Digital Systems Department, Western Road, Bracknell, Berks, RG12 1RA, England main contractors for digital equipment, software.
Plessey Radar Ltd, Addlestone, Surrey, England – displays, interface, and drive equipment.

1234.261

ADAWS 4 ACTION DATA AUTOMATION WEAPON SYSTEM

DESCRIPTION
This system is essentially a different version of the ADAWS 2, using the same hardware, but with variations to accommodate the requirements of the Type 42 guided missile destroyer class of vessels and the differences in armament compared with the Type 82 GMD with which the current ADAWS series originated. ADAWS 3 was designed for the CVA 01 carrier which was subsequently cancelled.

The ADAWS 4 is being produced in two slightly different versions for the RN Type 42 GMDs and the Type 42s on order for the Argentine Navy.

The central data processing complex consists of a suite of Ferranti FM1600 micro-circuit digital computers, with a Plessey Mk 8 digital display system for the presentation of tactical and other information. The computers provide a total of 128,000 words of core store, and they will gather data from all the ship's sensors, assemble and correlate this information and that from other vessels obtained via data link, and present it to the command teams on appropriate display consoles.

All information from 'own ship' and consorts in data link contact will be accessible at any console, and on a selective basis. For example, air situation or underwater situation. The computers also include programmes to assist in the evaluation of the relative threat posed by different targets, thus assisting the command in the selection of targets and assigning weapons. When action is joined, the computers also provide control of ship's weapons. In addition to providing all the aiming and fire control computations for the Type 42's Sea Dart missiles, the ADAWS 4 also includes fire control for the 4.5 inch automatic gun mounting, and the calculation of intercept instructions to be passed by radio to fighter aircraft or anti-submarine helicopters.

DEVELOPMENT:
Development of the ADAWS 4 is a continuation of the ADAWS 2 work, and began in 1967. Ferranti as prime contractor worked in collaboration with Plessey Radar as major subcontractor for the display system and with the British MoD

(Navy) and the Argentine naval authorities in respect of the Type 42 vessels for each of the two Navies.

STATUS:

Production of equipment for the first RN Type 42 had commenced in the summer of 1970, and orders have been received in respect of the two Type 42 GMDs for the Argentine Navy. Ferranti has announced that more than 50 of the FM1600 computers used in the ADAWS series have been ordered for these and other naval applications.

MANUFACTURERS:

Ferranti Ltd., Digital Equipment Division, Western Road, Bracknell, Berks, RG12 1RA, England.

Plessey Radar Ltd, Station Road, Addlestone, Surrey, England.

1235.261
ADAWS 5 ACTION DATA AUTOMATION WEAPON SYSTEM

DESCRIPTION:

This system is essentially a further version of the ADAWS 2 system (which see) that is fitted to the Type 82 guided missile destroyer HMS *Bristol*, and uses the same basic hardware and a large proportion of the software of that system, but configured to meet the requirements of vessels of the "Leander" class of frigates equipped with the Ikara ASW weapon system (which see).

From the information released it is not possible to amplify upon the system description as given for the other action data automation systems in this series, ADAWS 2 and 4, other than to say that the sensor, computer programming, and display arrangements for ADAWS 5 are optimised for the principal role of this class of vessel (ASW) and the Ikara anti-submarine weapon which is the main armament.

DEVELOPMENT:

Development has been carried out in conjunction with the other ADAWS programmes, by the same companies and government agencies, and originated in 1967.

STATUS:

In service.

MANUFACTURERS:

Ferranti Ltd., Digital Equipment Division, Western Road, Bracknell, Berks, RG12 1RA, England.

Plessey Radar Ltd, Station Road, Addlestone, Surrey, England.

1830.281
ADAWS 6 ACTION DATA AUTOMATION WEAPON SYSTEM

DESCRIPTION:

Although the designation ADAWS 6 has not been officially confirmed it can be stated with reasonable certainty that this is the correct title of the new system for the Royal Navy through-deck cruiser HMS *Invincible*. Ferranti and Plessey, who in partnership have produced most of the ADAWS for preceding RN ships, have been named as contractors for the computer complex and display systems for *Invincible*. Few details have been released concerning specific hardware or performance but it has been stated that two Ferranti FM1600 computers will be used and the Plessey contribution is valued at almost £1 million.

HMS *Invincible*, the largest ship to be built for the RN since World War II, is to have a more comprehensive automated AIO than any previous vessel, and its functions will include deployment and control of the ship's own weapons and aircraft as well as command and control of co-operating forces.

Invincible's probable armament includes the Sea Dart missile (two twin launchers), Sea King helicopters, and the later possibility of Exocet surface-to-surface missiles and Harrier V/STOL strike aircraft. Sensors will include a Type 965 long-range surveillance radar, IFF/SIF, Type 992Q search and target indication radar, two Type 909 radars for the Sea Dart system, Type 1006 navigation radar, data link, EW and probably sonar.

There is a significant area of commonality in both armament and sensors with other RN ships (Type 42 and Type 82) that have Ferranti/Plessey ADAWS, and as would be expected the new ADAWS for HMS *Invincible* will embody parts of the systems developed for these classes. In ADAWS 6 the two computers will function as a complementary pair, neither being dedicated to any particular task but both capable of performing all roles, sharing the data processing load as the situation demands. Additional software to meet the special requirements of the *Invincible*'s new operational role will be generated by a Ferranti team working at and in collaboration with the Admiralty Surface Weapons Establishment.

The Plessey display systems to be used represent a significant advance over those used in early ADA systems in that radar ranging, video processing, and processing of all target and synthetic data is carried out digitally. The display resolution and system accuracy necessary for air, surface and anti-submarine actions is achieved by the use of high-speed logic, which also ensures that maximum benefit is derived from the computerised data handling system.

STATUS:

In development.

MANUFACTURERS:

Ferranti Ltd., Digital Equipment Division, Western Road, Bracknell, Berks, England.

Plessey Radar Ltd, Station Road, Addlestone, Surrey, England.

1046.261
CAAIS – COMPUTER-ASSISTED ACTION INFORMATION SYSTEM

DESCRIPTION:

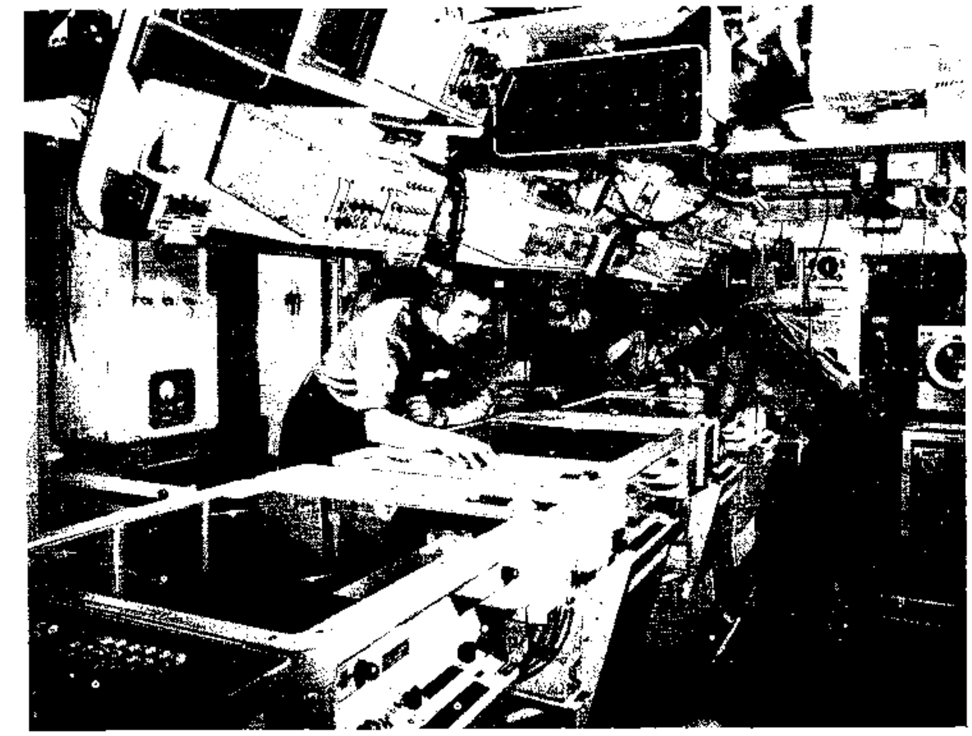
Shipborne operational data-handling and display system, based on the use of a digital computer (Ferranti FM1600B) but cheaper and less complicated than full action data automation systems.

OPERATION:

Optimal tactical appreciation and rapid deployment of naval units or weapons depends upon an accurate, up-to-date and clear presentation of the position, movement and identity of all friendly and enemy forces in the vicinity. Any one ship of a force may have vital information not obtainable by others; this must be passed to consorts and integrated with their own displays so that a common and unambiguous presentation of all information is available to the Command in every ship.

In 1966 MoD (N) recognised that solutions were possible using the techniques and principles previously evolved for the ADA systems. These were already fitted in larger ships of the Royal Navy, but a substantial reduction in cost and size would be essential if Computer Assisted Action Information Systems (CAAIS) were to be fitted in a useful number of anti-submarine frigates.

After deciding in principle that a system of viable cost, size and weight could be built largely from elements already available or under development in UK and in the light of operational experience already gained at sea, MoD (N) defined



Deccascan display consoles of the CAAIS installation on board the frigate HMS Torquay an operational requirement matched to the task. It permitted considerable reduction in complexity and cost by making full use of the man for assessment and decision while leaving the machine to collect, process and present tactical data and transfer it between ships.

In each ship of a force all available data on targets from own ship's sensors (including radar with auto tracking facilities, sonars passive direction-finding equipment) is injected together with a reference number – automatically or semi-automatically – into a computer which correlates it, stores, and calculates movement etc. Other input data includes navigational information from the ship's navigational equipment. Data thus stored is exchanged with consorts by digital data link so that each ship's store contains total and up-to-date information available to the whole force. This is presented – as required by individual users – by selection in alpha-numeric or symbolic form super-imposed on raw radar on a number of PPI displays. Data may be injected into store, altered or called up for presentation by operators using keyboards at the displays, which thus constitute the interface between man and machine. Data selected from the tactical displays can be transmitted for the direction of weapons.

Target designation is transmitted to weapon systems, and orders are displayed for helicopter anti-submarine attacks. Anti-submarine torpedoes may also be controlled.

A new approach to display and plotting techniques was also adopted for CAAIS, which led to the development of the Decca Radar Deccascan display system. This uses rotating coils for PPI deflection for the presentation of conventional radar data, and fixed coils for off-centring and presentation of symbolic and alpha-numeric 'labels'.

The Decca CA 1600 display employs a 16 inch (40 cm) CRT mounted with its face horizontal in a freestanding console. It is provided with a large parallax-free plotting surface. Two keyboard/tracker ball modules can be attached.

DEVELOPMENT:

Final development of the CAAIS was the responsibility of Ferranti as main contractor, and Decca Radar as principal sub-contractor. Development was in collaboration with the Admiralty Surface Weapons Establishment.

STATUS:

Two versions of the CAAIS were put into production in 1969 – DBA1 for general fitting or retro-fitting in ASW frigates of the Royal Navy, and DBA2 to be fitted in the Type 21 frigate. The Type 21 CAAIS installation will interface with the WSA-4 system installed to provide a two-tracker fire control system for the 4.5 inch Mk 8 gun and Seacat missiles. The first complete CAAIS to go to sea was installed on the training frigate HMS *Torquay* for sea trials in the latter part of 1972. CAAIS installations are in production or development for all Type 21 (Amazon class) and a number of Leander class frigates, and for HMS *Hermes* in her new configuration as a helicopter carrier.

MANUFACTURERS:

Ferranti Ltd. Digital Systems Department, Western Road, Bracknell, Berks, RG12 1RA, England – main contractor, development of digital equipment and software.

Decca Radar Ltd, Decca House, 9 Albert Embankment, London SE1, England – Deccascan displays.

1831.281

MINE COUNTER-MEASURE CAAIS

DESCRIPTION:

A contract worth approximately £750,000 was placed by the Ministry of Defence with the Ferranti Digital Systems Division in early 1974 to provide the first production FM1600B computer action-information system for the projected new class of Royal Navy mine counter-measure vessels (MCMV). Development of the necessary operational computer programs forms a major part of the work. This contract followed successful completion of a study project to assess the specific characteristics required of a computer information and control system for MCMVs.

The development of this special version of a computer-assisted action-information system (CAAIS) (see Entry **1046.261**) was entrusted to Ferranti by virtue of experience acquired by the Digital Systems Division in designing, installing and maintaining CAAIS systems for larger warships such as Amazon Type 21 frigates for the Royal Navy, HMS *Hermes*, and also the Mk 10 frigates now being built for the Brazilian Navy.

The new class of MCMVs have reinforced plastic hulls and one of the engineering tasks undertaken by Ferranti has been to reduce the magnetic signature of the computer equipment. At the heart of the system will be an FM1600B computer driving two Deccascan displays equipped with Ferranti manual input assemblies which enable operators to communicate with the computer by means of alpha-numeric keyboards and tracker balls.

The CAAIS system for MCMVs fulfils a triple role: it compiles and displays information with the speed and precision required for successful MCM operations; it makes the detailed calculations necessary for the accurate navigation and control of the ship; and, as in all CAAIS systems, it provides a comprehensive display of the tactical situation, such as would be required when the ship is on patrol duties.

The ability of the CAAIS system to automatically accept and process sensor information presents the Command with the ability to reduce errors and action-time operator fatigue, and generally to increase the MCMV's ability to meet its designated task.

MANUFACTURERS:

Ferranti Ltd, Digital Systems Division, Western Road, Bracknell, Berks RG12 1RA, England.

Decca Radar Ltd, Decca House, 9 Albert Embankment, London SE1, England.

1496.281

WSA-4 FIRE CONTROL SYSTEM

DESCRIPTION:

WSA-4, Weapon System Automation Mk 4 is the digital weapon control system designed for the new Type 21 ("Amazon" class) of RN Frigates. In these ships WSA-4 will interface with the Computer Assisted Action Information System (CAAIS– Entry No. **1046.261**) and, like that system is based on the Ferranti FM1600B digital computer. The system has been designed to fully utilise the capabilities of the Weapons and Sensors and minimise reaction times, whilst being capable of operation with a very small crew. Weapon direction and target designation is normally performed at a CAAIS display position. Targets selected at the display are indicated to the relevant tracker radars which are automatically controlled to search and acquire the target. Visual weapon direction facilities are also incorporated. Weapons controlled by the system are the Seacat missile and 4.5 inch (114 mm) gun used in conjunction with two Orion RTN-10X fire control radar equipments (see entry No. **1368.253**). The Orion radar heads are equipped with closed circuit TV cameras for Seacat operation.

The system includes facilities for operation in the event of breakdown or damage to the primary system. The Seacat can be aimed and fired in visual control from the Pedestal Sight while the gun can carry out surface engagements under the control of the Lookout Aiming Sight, with fire control corrections being applied at an Emergency Fire Control Box.

STATUS:

Trials of the first system in HMS *Amazon*, are at an advanced stage, and three further installations have been ordered for the following vessels in this class.

MANUFACTURERS:

Ferranti Ltd, Digital Systems Department, Western Road, Bracknell, Berks, RG12 1RA, England.

Decca Radar Ltd, Decca House, 9 Albert Embankment, London SE1, England.

1363.261

COMMODORE A I O SYSTEM

DESCRIPTION:

This is a flexible AIO system designed especially for small ships. It co-ordinates inputs of tactical data during operations and presents this in a readily assimilable form. It will solve all ship handling and tactical problems and output the directions to gun, missile and torpedo aiming systems while automatically keeping continuously updated tracks on up to 20 targets, with manually rate-aided tracking on more if required. If the system includes a data link Commodore will automatically format and compile messages for transmission to shore bases or co-operating forces. Incoming information is similarly accepted and processed for immediate display or action on board. The heart of the system is one of the Marconi-Elliott 900 series of digital computers.

All the operator controls and interfaces are flexible and logical for unambiguous input and output of data. The display facilities provide precise selection of part of the tactical picture area to the exclusion of all other information.

The interfacing facilities are designed for single logical control and consist of PPI, in relative, true motion or off-centred modes, for the presentation of an interlaced radar/symbol picture and a readout for track, supplementary information and solutions to tactical problems. Manual input to the system is by a rolling ball controller and keyboard, and there are also facilities for range scale and symbol category selection. One feature of the system is that all operating stations are completely independent.

OPERATION:

The Commodore will input from a radio link, radar, ship's log, heading gyro, stabilisation unit, visual, and the radar display. Information is then output to the radio link, the radar display, torpedoes, missile and gun stations. Individual system facilities may be selected from the following.

Radar:

Inputs accepted from up to 3 radars.

Auto track facility for tracking up to 20 targets.

Manual rate-aided tracking facilities as a backup and for additional targets.

Link:

Processing of data link information for exchange between co-operating units.

Search Radars:

Display of 8 bearing lines.

Display of search receiver fix and probability area.

Sonar:

Inputs accepted from up to 3 sonars.

4 sonar tracks each with 7 positions displayed in a 'ripple'.

3 datums each surrounded by 16 points representing a 'furthest on circle'

Log and Gyro:

Inputs accepted from log and gyro.

Capacity:

60 tracks (but max auto track 20 and max bearing 8)

Target Indication:
To 3 weapon systems.
Display Console:
PPI incorporating readout for display of target supplementary information, solutions to problems, and manual injection sequences.
Range scale selection.
Off centring and true motion available.
Category selection of symbols.
Radar selection.
Selection of radar or symbols or radar and symbols.
Rolling ball and manual injection keyboard.
Other Facilities:
Sonar contact association programme.
Helicopter control.
Solution of ship handling relative velocity problems.
Past positions of surface tracks stored for display on request.
Display of weapon danger zone.
MANUFACTURER:
Marconi Space and Defence Systems Ltd, Naval Division, Chobham Road, Frimley, Camberley, Surrey, England.

1828.261
MARCONI/SPERRY LIGHTWEIGHT GUNFIRE CONTROL SYSTEM

DESCRIPTION:
Sperry Gyroscope and Marconi Radar Systems have collaborated to create a cost effective Lightweight Gunfire Control System. Designed for any size of warship from fast patrol boats upwards, the system is capable of maintaining rapid and accurate control over small and medium calibre guns against air, surface and shore targets. The system is fully automatic, thus keeping manning requirements to a minimum – only one man, in an essentially supervisory role, is required to operate the system.
The main components of the system are:
(a) The Marconi 800 series autonomous tracking radar, ST802 (Entry **1508.253**).
(b) The Sperry Digital Predictor consisting of the Sperry 1412 Computer (Entry **1443.063**), associated interfaces and power unit.
(c) The Control Console, incorporating the display and control units for one man to supervise the radar, predictor and gun.
The total package is designed to be compact and lightweight, thus being suitable for installation in FPBs, Corvettes, Frigates, etc. The predictor uses a dedicated computer leading to operational simplicity and autonomous operation. The radar uses monopulse processing giving a significant advantage in that it is free from fade noise when compared with a conical scan radar. The system will control servo-operated guns with calibres from 20 mm upwards.
In order to make full use of the possible roles of naval guns the system offers three modes of operation:
(a) Anti-Aircraft (AA) for defence against high and low level air targets;
(b) Surface (SU) for use against surface vessels moving at speeds up to 60 knots;
(c) Naval Gunfire Support (NGS) including:
  (i) Direct Bombardment. This mode of operation is used for bombardment of a shore target visible from the ship;
  (ii) Indirect Bombardment. In this mode of operation the gun is trained on to a shore target using spotting corrections from a shore observer;
  (iii) Blind Bombardment. This is used to bombard a point defined by present range, bearing and height from map co-ordinates.
  (iv) 'Radar Assisted' Bombardment. This is used when a discrete radar echo ashore can be tracked. Offsets are then added using map co-ordinates to take account of the separation between the radar echo and the required target.
In SU and NGS modes, fuse computation is provided for use with star-shell and window. The system can also be used to give surveillance information by means of horizon search or sector scan.
DEVELOPMENT:
During 1973, aircraft tracking trials proved the ability of the system to acquire rapidly, and provide, smooth training and elevation signals to a typical AA gun. Firing trials using a medium calibre gun against surface and air targets, to prove the overall system, will take place in 1974.

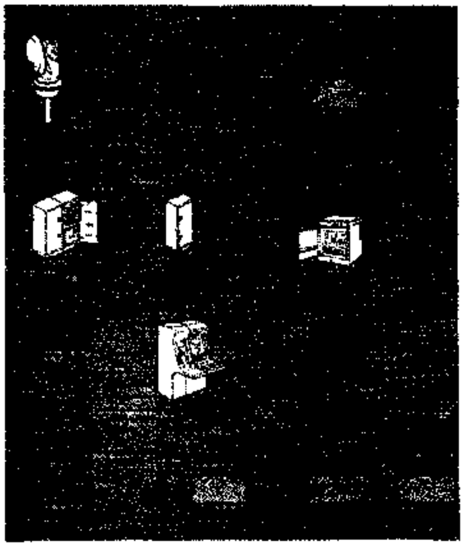


Diagram of Marconi/Sperry Lightweight GFCS

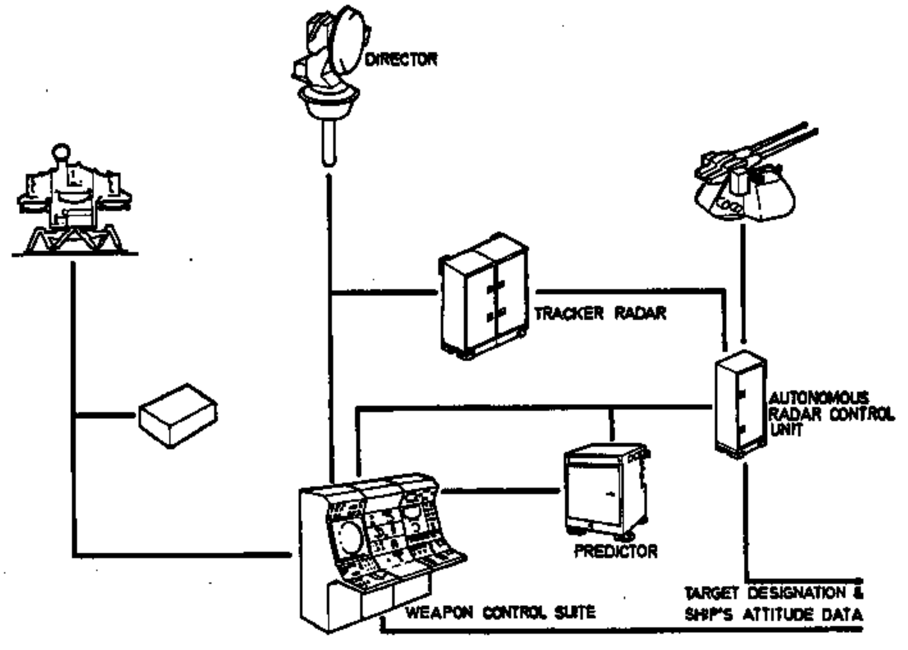
STATUS:
Proposals and submissions have been prepared. On the strength of the interest shown, small production quantities have been initiated by the two companies.
MANUFACTURERS:
Sperry Gyroscope, Downshire Way, Bracknell, Berkshire.
Marconi Radar Systems, New Parks, Leicester.

1829.281
MARCONI WEAPONS CONTROL SYSTEMS

DESCRIPTION:
The Marconi Company has followed the development of the 800 series radars with the development of integrated Naval Fire Control Systems for use with guns, surface-to-air and surface-to-surface missiles. There has been extensive co-operation with many UK companies, notably Short Brothers (Seacat missile) and Sperry UK Limited, (Digital Gunfire Predictor). The range of available systems is already extensive, and is being expanded to control different types of gun mounts and missile systems.
The Weapons Control Systems fall into three main categories:
1 Those based on surveillance radars – CS series;
2 Those based on tracking radars – CT series;
3 Those incorporating both surveillance and tracking radars – CST series

CS SERIES:
The Marconi Company manufactures a range of surveillance radars operating in the L, S and X-bands, and any of these with the appropriate Tactical Command System can form the basis of an effective anti-surface weapon control system as simple or as sophisticated as required. In its simplest form, the system provides target data to remote weapon systems. The addition of automatic track-while-scan facilities and a Sperry digital predictor allows control of a surface-to-surface missile system and guns against surface or shore targets. A limited anti-aircraft gunfire capability can be achieved by the incorporation of an optical sight for the provision of elevation data. These systems can constitute the complete fit for, say, a picket boat or may be used to update existing systems on larger vessels being retrofitted with surface-to-surface missiles.



CT Series system for gunfire control and dark-fire and blind-fire capabilities for the Seacat missile

CT SERIES:
These systems are based on fully-automatic light-weight tracker radar giving accurate space-stabilised target data for a variety of weapon

control systems. Packages already developed give a dark-fire and blind-fire capability to the Short Brothers Seacat missile system through the incorporation of a boresight television camera system, and accurate control of gunfire with the addition of a Sperry digital predictor. A system is available for the control of two different calibres (30 mm and 120 mm) and work continues to adapt the system to other calibres. The tracking radar is the Marconi ST802 (Entry **1508.253**), which provides automatic acquisition and tracking of targets. For acquisition the radar generates its own stabilised search patterns based on target range and azimuth data obtained via the Tactical Command System. It is an X-Band pulse doppler tracker with extensive ECCM facilities and is capable of continuous rotation in azimuth. It may be used to provide a stabilised horizon search which is particularly effective against low flying aircraft and sea skimming missiles.

The digital gunfire predictor provides accurate control of the light gun but, if required, a second gun mount may also be controlled. The tracking radar console includes a splash spotting display.

Defence against aircraft is provided by the Shorts lightweight Seacat control system. This has been developed jointly by Marconi and Shorts, and includes the ST802 tracker radar fitted with the Marconi V1000 TV system for automatic missile gathering. Two versions of the tracker are available providing ''dark fire'' and ''blind fire'' of the missile. In both versions the target is tracked by the radar, but for ''dark fire'' the TV is used to control the missile to the sight line. In the ''blind fire'' version the radar tracks both target and missile.

The packages are completely autonomous apart from the need for target indication and ship's attitude data; but also available is a version of the tracker (ST801) which can be controlled directly from the data handling centre of an existing action information system. In each system, the Tactical Command System incorporates the full range of status and control facilities at one location giving true autonomous operation.

CST SERIES:

This is a series of fully integrated systems comprising combinations of the various CS and CT systems. They are designed primarily for the modern Fast Patrol Boat and its enhanced fire power, but they also meet the needs of corvettes or larger warships. In the typical FPB system illustrated, any one of four surveillance radars may be fitted. They are all 200 kW X-Band radars, fully stabilised against ship's motion. The radars differ in size of antennae (1.25 metres for S810/811, 2.50 metres for S815/S816) and provision of digital MTI (S810 and S815). Air coverage is provided to 40 km.

Target detection, tracking, threat evaluation and weapon assignment are carried out using the Tactical Command System which is tailored to meet the particular needs of the ship. Normally the ST802 tracking radar is used to provide accurate target indication data to the appropriate weapon systems, but for simultaneous engagement of air and surface targets, the surveillance radar is used for controlling gunfire against the surface target, and the tracker is used to control missile engagement of the air target.

Target tracking, gun and missile control facilities are identical to those provided with the CT series weapon systems. The tracker and surveillance radars utilise a large number of common components, thus keeping to a minimum the number of on-board or base spares required. Target indication data may also be transmitted to a surface-to-surface missile control system such as that for Exocet or Otomat.

Additional sensors such as Electronics Warfare receivers and optical sights may be included in the system, to provide more comprehensive picture compilation and weapon control facilities. In particular Seacat can be controlled optically, as was the original version of the missile. A portable, on board radar simulator is available for operational training purposes.

THE UNITED STATES OF AMERICA

1666.261
GUN DIRECTOR MK 35 MOD 0

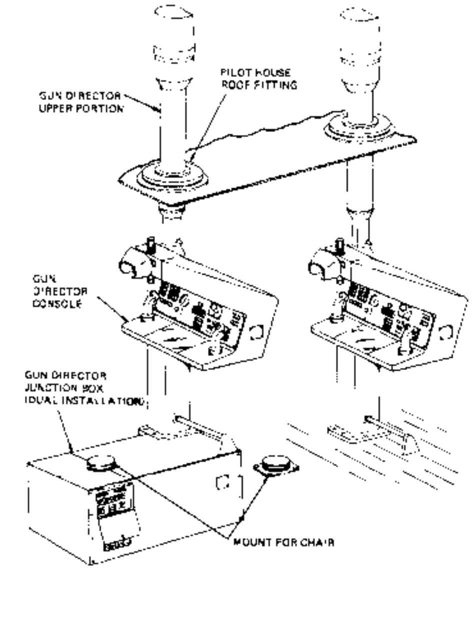
DESCRIPTION:

The Mk 35 Mod 0 Gun Director is a ship-board system for acquiring and tracking surface and air targets and engaging them with automatic gun fire. It incorporates a dual-power optical system, with day and night viewing capabilities, the line of sight being internally stabilised to the deck plane, to compensate for pitch and roll. The director combines inputs of radar (not part of system), computer, and optical scanning, under the control of the operator. Gun mounts, when under control of the director, are slaved to it.

The complete installation comprises two gun directors (No. 1 Forward, No. 2 Aft) with one junction box serving both directors. Each director head contains a head prism which can be rotated through 360 degrees (continuous) in azimuth and slewed in elevation between +80 degrees and −30 degrees. An image-intensifier tube can be interposed in the optical path to provide night vision capabilities. Controls and indicators are grouped on the two operator consoles associated with the No. 1 and No. 2 director heads. Provision is made for optical or radar ranging techniques.

MANUFACTURER:

Kollmorgen Corporation, Electro-Optical Division, Northampton, Massachusetts 01060, USA.



Shipboard installation of two Mk 35 Mod 0 gun directors

1832.261
GUN FIRE CONTROL SYSTEM MK 37

DESCRIPTION:
The GFCS Mk 37, although undeniably old and dating back to World War II years, is still in widespread use by many navies and was known to have remained in US Navy service until at least 1969. Because of a more or less continuous process of modification and improvement over a period of more than 20 years and at least 14 user nations, a detailed description of the equipment is virtually impossible. During this time various radars have been used with the Gun Director Mk 37 which provides stabilised optical and radar lines of sight to a computer (usually a Mk 1A) and, by tracking manually or with rate control, establishes and corrects target rates. Different users are likely to have changed the computer facilities to meet their own particular needs.
The main function of the system is the control of 5-inch/38 calibre guns against surface or air targets, but it has also been applied to the direction of 3-inch/50 calibre and 40 mm guns, as well as 6-inch and larger guns for barrage fire against air targets. The system has been installed aboard destroyers, light and heavy cruisers, battleships, aircraft carriers and some auxiliaries. It is also used as a battery control and a spotting station.

DEVELOPMENT:
Development was completed in time for the GFCS Mk 37 to see service in World War II. It has been the subject of various modification and updating programmes since production ceased in 1946.

STATUS:
A total of 1013 units were built, 413 by the US Naval Gun Factory and 600 by General Electric. Users, either current or within recent years, include: Argentina, Brazil, Chile, Colombia, Germany (Fed. Rep), Greece, Italy, Japan, Korea (S), Peru, Taiwan, Turkey, USA.

MANUFACTURER:
General Electric Company, Ordnance Systems, Electronic Systems Division, Pittsfield, Mass. 01201, USA.

2633.281
GUN FIRE CONTROL SYSTEM Mk 56

Gun Fire Control System (GFCS) Mk 56 is a shipboard, intermediate range anti-aircraft, gun fire control system designed for use against subsonic aircraft and surface targets.
Its primary functions are first to track aircraft targets and secondly to compute train, elevation, parallax, and fuse orders for shipboard guns. The system can also be used to control gun fire against surface targets and shore installations.
To accomplish its purpose, the system uses a radar sub-system for automatic tracking of either visible or obscured targets, an optical sub-system for tracking visible targets, an electromechanical sub-system for computing gun orders, and servomechanisms for operating the director power drives.
GFCS Mk 56 may be used against different types of targets under different operational modes. The computing sub-system is designed for optimum performance against the types of target most dangerous to own ship, which are incoming high speed torpedo planes, dive bombers, and medium altitude bombers. At slightly less effectiveness, the system can also be used against all types of surface vessels and shore installations.

SYSTEM FUNCTION:
The Mk 35 X-band radar is of conventional auto-follow design, the elevation and traverse error signals derived from the radar receiver when the target moves away from the radar line-of-sight being used to servo the radar antenna back on target. Inserted in the servo loop are the tracking control circuits which accept the error signal inputs and process them to produce, on the one hand, tracking signals for the antenna power drives and, on the other hand, elevation and traverse rate outputs to the fire control computer.
The tracking signals are passed to a gyro unit which modifies them so that the demands on the antenna power drives are modified to allow for the pitch and roll of the ship. The gyro and power drive units form part of the Gun Director, and from this sub-system are taken two sets of outputs to the computer, one set defining the target line of sight relative to the ship and the other set defining it relative to the gyro platform.
Other inputs to the computer are own ship's speed and course taken from the log and gyrocompass and target range from the radar. In addition values are set in for gun dead time and initial velocity and true wind speed and direction. From this information and the fixed displacements between the guns and the radar antenna the computer generates train elevation and fuse orders for the guns.

DEVELOPMENT HISTORY:
Development of the system was initiated by the US Navy at Massachusetts Institute of Technology in 1942 with industrial support furnished by the General Electric Company and the system went into service in the USA in 1947. More than 700 systems were delivered, and although production ceased in 1955 the system is still widely deployed, particularly in US forces but also in eleven other countries.

STATUS:
Obsolescent but navies known to have Mk 56 fittings in recent years are those of the USA, Argentina, Brazil, Chile, Taiwan, Colombia, German Federal Republic, Greece, Japan, Peru, Spain and Turkey.

MANUFACTURERS:
Complete System: General Electric Company, Ordnance Systems, Electronic Systems Division, Pittsfield, Massachusetts.

Telescope: Kollmorgen Optical Co.
Radar: General Electric Co, Syracuse N.Y.
Wind Transmitter and Parallax Corrector: Reeves Instrument Co; Belock Co.

2634.281
GUN AND GUIDED MISSILE FIRE CONTROL SYSTEM Mk 74

Similar in general conception to the Gun Fire Control System Mk 56 (q.v.) the Gun and Guided Missile Fire Control System Mk 74 is a modern system that is both electronically and mechanically of far more advanced design. It is a shipboard system designed for the control of guns or guided missiles and with the capability of performing its target acquisition, tracking and control functions against targets flying at supersonic speeds.
Main elements of the system are the Gun and Guided Missile Director Mk 73, the Radar Set AN/SPG-51 and the Computer Mk 118. The radar is in two parts, the transmitter-receiver rotating with the director and antenna assembly and being connected to the remainder of the equipment through slip rings.

SYSTEM FUNCTION:
Weapon detection equipment (not part of the GMFCS Mk 74) designates targets to the radar, computer and director, and the radar and director synchronize to this signal. The computer then generates a search pattern which the director and radar follow until the target is acquired.
When the radar and director have acquired the target they track it under computer control. The range and angular error data derived by the radar are fed directly into the computer and the computer generates the rate signals that are used to control the angular motion of the director.
Once the radar and director are tracking smoothly the computer generates fire control data and transmits gun mount and/or missile launcher position orders to the appropriate stations. It also provides missile seeker angle data as appropriate.

STATUS AND MANUFACTURERS:
In current production as part of the Tartar weapon system.
Main contractor for Tartar: General Dynamics Corporation, Pomona Division, Pomona, California.
Gun and Guided Missile Director Mk 73: General Electric Company Ordnance Systems, Electronic Systems Division, Pittsfield, Massachusetts, USA.

2632.281
GUN AND GUIDED MISSILE DIRECTOR Mk 73

This equipment is a major component of the Gun and Guided Missile Fire Control System Mk 74, one application of which is to the Tartar surface-to-air guided weapon system. Gun and Guided Missile Director Mk 73 is an unmanned, amplidyne-controlled, direct-drive motor-driven 2-axis unit. It serves as a mount for the antenna and part of the electronics of another major component of the system – Radar Set AN/SPG-51. The radar line of sight can be rotated continuously in train and can be elevated from −30 degrees to +83 degrees relative to the deck plane.

DEVELOPMENT HISTORY:
In common with other Tartar sub-systems, development of the director began in 1956. The first prototype was completed in 1958 and the equipment went into service in 1960. Currently in production, 122 equipments have been delivered to date for use in US Navy and foreign ships. Four more sets were ordered in early 1974.

MANUFACTURER:
General Electric Company, Ordnance Systems, Electronic Systems Division, Pittsfield, Massachusetts, USA.

1241.281
GUN FIRE CONTROL SYSTEM Mk 86
DESCRIPTION:
This ship's fire control system uses three sub-systems, surface and air target radars, and a remote-controlled television system, for the direction of gun-fire against surface and aircraft targets. A general-purpose digital computer is employed for the rapid processing of target data, ballistics, and computation of range and training parameters for guns.
The radar for surface target engagement is the AN/SPQ-9, a track-while-scan system. The aerial is protected by a spherical radome of estimated diameter 300 cms. This is supported on a cylindrical pedestal about 300 cms high. The remote TV camera sub-system is mounted at the foot of the pedestal, and this probably also incorporates optical sighting elements. For use against air targets, a pulse-doppler and AN/SPQ-60 tracking radar is provided.
DEVELOPMENT:
Initial in-house studies were started by Lockheed in 1961, and the first prototype was completed in 1966.
STATUS:
Two prototypes had been delivered to the USN by March 1970. Production has started, and by March 1973 16 sets had been completed when a contract for a further 11 systems was awarded by the US Naval Ordnance Systems Command. This contract included an option to purchase a further seven systems, and this option was taken up in January 1974 to bring the total number ordered to 34. The Mk 86 GFCS is used in the US Navy's new fleet of helicopter assault ships (LHAs), Spruance class destroyers, and DLG(N)-36 and -38 nuclear-powered guided missile frigates.

MANUFACTURER:
Lockheed Electronics Company, Route 22, Plainfield, New Jersey 07060, USA.

1260.281
GUN FIRE CONTROL SYSTEM Mk 87
DESCRIPTION:
This is the US designation for the Signaal M22 system described in Entry No. **1259.261**. Licence manufacturing rights were acquired by Sperry Rand and procurement for the US Navy was authorised in 1964. A successful land-based evaluation was started in 1966, and a technical and operational evaluation was started aboard the USS *Antelope* in January 1968. Preliminary findings of these evaluations reveal the Mk 87 as far superior to the Mk 63 FCS now being fitted under the new ship construction programme. It was also stated to be cheaper over a 10-year life-span.
However, the only vessels in the approved new construction programme in May 1969, when the Mk 87 was reviewed by the Committee on Armed Services in the House of Representatives, for which the system was suitable were 20 tank landing ships and 10 motor gun boats. Secretary of Defense, Melvin R. Laird, stated that to fit the Mk 87 to these craft would delay their completion and therefore the decision to fit the Mk 63 should stand. Seven other vessels in future building programmes are planned to have the Mk 87, but its procurement in Fiscal Year 1970 was not required.

1835.281
FIRE CONTROL SYSTEM Mk 92
DESCRIPTION:
The Mk 92 FCS is under development for fitting in two new classes of USN ships, the Patrol Frigate and Patrol Hydrofoil, Missile, (PF and PHM). The latter is also known as the NATO Hydrofoil, since the overall programme of development and construction is being carried out in collaboration with W. Germany and Italy, who both plan to have essentially the same craft but differing in some aspects of weapon and sensor fits. One such variation is in respect of the fire control system: the Italian Navy will employ an Argo FCS, while the USN and German Bundesmarine will have virtually the same system, namely the Hollandse Signaalapparaten M28 which has been given the American designation Mk 92, and which will be produced under licence in the USA by Sperry Gyroscope. Details of the M20 Series of HSA fire control systems will be found in Entry No. **1359.291**, a few pages earlier in this section.
The Mk 92 is very similar to the M25 and M27 systems built by HSA for the Belgian, German and Netherlands navies, the former providing for control of air and surface engagements by guns and missiles, while the M27 additionally has provision for torpedo control. The Mk 92 will be used for air and surface actions using guns and missiles, and there are a number of other changes from the basic M25/M27 configuration to suit USN requirements. In compliance with the differing sensor arrangements and armament in the two classes of USN vessels to be fitted with the Mk 92 this system will be produced in different versions, and the Mk 92 Mod 2 for the Patrol Frigate. An Mod 0 version has been built for the initial test, evaluation, and proving procedures starting in 1974.
PATROL HYDROFOIL, MISSILE:
The USN variant of the PHM will have as its armament eight Harpoon anti-ship missiles (**2641.221**), and an Oto-Melara 76 mm dual-purpose gun. In addition to the co-mounted search and tracking radars which are a feature of the M20 Series fire control system, other sensors will include an X-band navigation radar, inertial navigation system, and an Electronic Warfare suite. Current plans call for a total USN force of 30 of these ships by 1977/8.
PATROL FRIGATE:
The new class of Patrol Frigate (PF) for the US Navy will have as its principal operational roles Anti-Submarine Warfare, Anti-Air Warfare including both anti-aircraft and anti-missile capability, and anti-ship missions. These ships will have a dual-purpose launcher able to launch either Harpoon surface-to-surface or Standard surface-to-air missiles. Other armament will include a US-built Oto-Melara 76 mm dual purpose gun (Mk 75).
The Mk 92 Mod 2 FCS for this class of vessel will operate within a more elaborate environment than the PHM's Mod 1 version. In addition to its own search and tracking radars (with integral IFF), other sensor equipment will include an AN/SPS-49 search radar, AN/SPS-55 X-band navigation radar, and an AN/SPG-60 STIR (Standard Target Illuminating Radar). The Mk 92 system's radar will be provided with an additional CW illuminating radar transmitter of US origin, and in the Mod 2 version the original Dutch digital computer will be replaced by a Univac UYK-7 machine. The complete Mk 92 Mod 2 is to be integrated with the ship's digital rapid reaction command and control system, which is one reason for the change of computer which eases the interfacing problems.
In the period 1974 to 1979 the USN plans to procure a total fleet of 50 PF ships, the current programme being for construction of the first seven vessels. Shore and sea trials of the Mk 92 will be carried out in advance and concurrently with building of the lead PF ship. Sea trials will be carried out aboard the USS Talbot (DEG-4).

MANUFACTURER:
Sperry Gyroscope, USA.

1307.231
SAMID – SHIP ANTI-MISSILE INTEGRATED DEFENCE
DESCRIPTION:
This programme is to a large extent the American response to the Egyptian sinking of the Israeli destroyer Eilath in October 1967 with a Soviet-designed Styx anti-shipping missile, and to other factors giving the US Navy concern regarding weapons of this type. These factors include, according to Congressional statements, continuing increases in the number and types of anti-shipping missiles available to the USSR forces; the variety of available launch platforms (ships of most sizes, aircraft, submarines and shore sites); and Soviet exports of anti-shipping missiles. Although struck from the Congressional record, it is believed that it was also stated that the USN had a limited capability to counter such weapons, apart from the capability to destroy the launch platforms.
Only very broad indications have been given of the means adopted to counter the threat of anti-shipping missiles under the SAMID programme. Improved passive electronic warfare sensors and active deception measures are among those known to be involved, and the use of chaff dispensing rockets to confuse the incoming missiles' radar homing is a further provision.
Relatively simple modifications have been evolved for several search radars to improve their clutter performance, and the man/machine interface.
Fire control radars were given the best available modifications (i.e. those that could be applied without extensive design or new research effort) to improve detection, acquisition and tracking capabilities against anti-shipping missiles. Another measure was a major effort to achieve far greater integration of the ship's active and passive sensors with all other elements of the ship. This was accomplished by the introduction of data transfer units, and has the effect of considerably reducing the reaction time to anti-shipping missile threats. It also permitted a better utilisation of the counter-measures and defensive weapons available.
On-board training facilities were also improved by the provision of an ECM signal generator. Type 15E27 and an AN/SPH-1 radar video recorder which enabled simulated attacks to be generated.
STATUS:
Active development continues, and the system will be installed initially in US Navy guided missile destroyers (DDG), "Belknap" class frigates (DLG), and "Gearing" class destroyers (DD). Evaluation is in progress in USS Towers (DDG).

1493.261
US NAVAL TACTICAL DATA SYSTEM
DESCRIPTION:

NTDS, Naval Tactical Data System is the designation given to the combinations of digital computers, displays of various types, and data links which are installed on US Navy ships for the on-line collection, processing, storage, and presentation of information from sensors such as sonar, radar, optical, and aircraft or ship consorts, via data link. NTDS also is engineered to interface with ATDS (Airborne Tactical Data System) and MTDS (Marine Tactical Data System). All three systems have the prime function of providing for automated organisation and display of information for command and control teams for such purposes as threat detection and assessment, and weapon-target allocation.

Although designed to a common concept, NTDS exists in a number of versions, varying in size and equipment complement according to the age of installation and the size of vessel fitted. The overall system has also been subject to a continuous process of updating since its introduction into service in the late 1950s. By 1969, for instance, three generations of display devices had been employed. The basic digital computer for the system, the AN/USQ-20, was preceded in some installations by other types, and newer NTDS will employ the Univac AN/UYK-7 (Entry No. **1467.063**).

STATUS:

By 1969, 30 USN ships had been fitted, in aircraft carriers, guided missile frigates and cruisers, and installations are now approaching 50 in number. Versions of NTDS are planned for most new construction attack vessels, the most significant being the 30 DD-963 destroyers to be built by Litton.

1834.281
AEGIS COMMAND AND CONTROL SYSTEM
DESCRIPTION:

Aegis represents the latest development in the evolution of AAW (Anti-Air Warfare) combat systems. The AN/SPY-1 introduces a fully automatic radar to perform search and tracking, and the use of a midcourse-commanded missile increases the firepower of the ship. The introduction of these innovations into the fleet with the attendant high target-handling capability brings a requirement for considerable expansion of automation in C and C and requires that command be exercised by negation.

The aspects of Aegis as an anti-aircraft and anti-missile weapon system are described more fully in Entry No. **2507.231**, in an earlier section of this volume, this entry being more directly concerned with the C and C features of the system.

Originally, Aegis was designed for installation in a 10,000-ton DLGN-38 class ship. The paragraphs that follow briefly describe this ship s combat system and the role of C and C within it.

The combat system of the DLGN-38 ship is shown in simplified form in Fig. 1. The Aegis part of the system consists of Radar Set, AN/SPY-1; Weapon Direction System (WDS), Mk 12; Fire Control System Mk 99 (consisting of a Tracking Illuminator, Mk 91 and Slaved Illuminator, Mk 90) the Guided Missile Launchers, Mk 26; the midcourse-command-version of the standard missile, SM-2; and finally the Aegis portion of the C and C system, Mk 130.

In addition to AAW, this ship also performs surface warfare and anti-submarine warfare missions. These missions, as well as Aegis, are supported by the additional sensors shown in Fig. 1 and by the gun and underwater-battery fire-control systems; the latter shares one of the launchers with Aegis. The C and C system integrates the Aegis and non-Aegis elements into a total combat system, and interfaces these elements with command personnel in CIC.

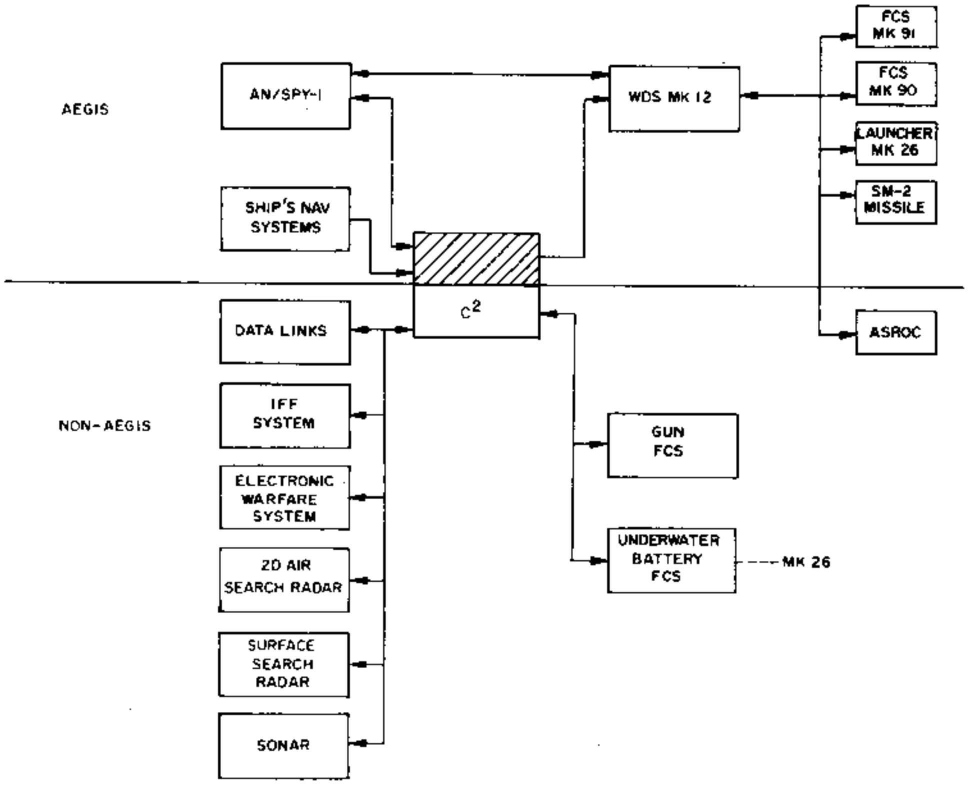

Figure 1. DLGN-38 Combat System

The baseline design of the C and C segment in the Aegis combat ship was based on the use of standard digital computers (AN/UYK-7) and associated peripherals, and an updated general purpose display system, Display Group AN/UYA-4. Auxiliary equipment in the system includes switching equipment, a digital clock, a magnetic disc and a multiplexer to allow non-C and C computers to assess the disc.

The operation of the Aegis weapon system is shown in Fig. 2. It begins with a search-and-detect operation by the phased-array radar. A detected target is placed into track by the radar and passed to the command-and-control system for evaluation. Once a target is determined to be a threat by the C-and-C system, orders are furnished to the weapon-direction system to develop a fire-control solution. Missiles are loaded on the launcher by commands furnished by the weapon-direction system. The phased-array radar furnishes target track data to the fire control system which designates the launcher firing position through the weapon-direction system.

After launch, the missile is guided by the phased-array radar until the homing phase of the flight at which time the fire-control system illuminator is slaved to target coordinates supplied by the radar, thereby furnishing the illumination on which the missile can home. Following intercept, the illuminator is available for the next threat. In the meantime, the multifunction phased-array radar, coupled with the multicomputer control system, continuously searches for new targets and simultaneously tracks targets already detected or engaged. The result is virtually instantaneous response to any new single or multiple threat that evolves.

The overall system control of Aegis is exercised through the console operators. These operators insert 'doctrine', select targets for various actions, and establish modes of operation. The UYA-4 consoles are usually co-located in a Combat Information Center (CIC) for ease of operator communications.

The ATC (Aegis Tactical Coordinator) is the lead operator. The main functions of the ATC are to supervise the overall conduct and operation of the CIC; insert tactical doctrine, threshold values, and own ship position data; and evaluate the computed threat potential of targets and assign weapons to the MSS/EC when required.

The MSS/EC (Missile System Supervisor/Engagement Controller) combines positions normally separately manned. He provides operator control of the weapon system. His main functions are to assign launcher and illuminator and mode of operation, monitor launcher and illuminator status, monitor engageability of selected targets, control firing and re-firing, monitor missile status, and monitor air engagements.

The SS (Sensor Supervisor) interacts with the Detector Tracker (see below) and provides a degree of track management. His main functions are to delete targets from the C and C system if the track load becomes too great, perform manual tracking using radar video displayed on the PPI, and enable use of SPY-1's burnthrough mode.

The DT (Detector Tracker) reports to the sensor supervisor in the organi ational structure. He has a direct counterpart in the NTDS system and does manual tracking in support of the SS.

ELECTRONIC WARFARE SYSTEMS

Because, in general, the efficiency of a nation's electronic warfare (EW) systems and equipment is enhanced by denying possible opponents information on its operation, performance and the level of technology attained in this area, it is not possible to either apply the same treatment to this subject as that applied in Jane's Weapon Systems to other aspects of military equipment or to suggest that what can be described is representative of the latest state of the art.

Nevertheless EW is too important to be disregarded, and the following notes and entries have been compiled to enable readers to place in perspective what information is available and any other data which they may individually acquire.

EW Objectives:

Military electronic systems are mostly employed either to obtain information concerning an enemy, or to assist in the use of such information in support of one's own actions against that enemy. Examples are radar to detect and track targets, and radio command links to guide missiles to the targets. In this simple case the attacker would use ECM to (1) try to avoid detection, (2) prevent tracking, and (3) to interfere with the defender's missile guidance. The defender would employ ECCM techniques to counteract the attacker's attempts. He also would employ ECM to oppose those attacker's electronic systems that are necessary for performance of the attack.

Elint:

There is a whole range of EW equipment dedicated to the gathering and collation of as much data as possible within practically the entire electro-magnetic spectrum. This area of EW is usually referred to as Elint (Electronic Intelligence) or electronic reconnaissance. Companion disciplines, which can employ similar techniques but which have different objectives, are Comint (Communications Intelligence) and Sigint (Signals Intelligence). It is not proposed to elaborate upon these activities in this section but their principal function is the interception and monitoring of enemy, and possibly friendly or neutral, communications traffic of all kinds. Though this may on occasion yield direct information of military or political value, there are important secondary forms of data that can be derived from Comint and Sigint operations. These may range from indications of possible intentions which can be deduced from changes in the levels of signals activity in differing geographical locations, to tactical intelligence obtained by recording the locations of identified signal sources.

While overlapping communications monitoring to some extent, Elint is mainly concerned with the collection and analysis of electronic radiation from sources other than communications systems. Elint is performed on a regular basis in times of peace, prior to specific missions under actual war conditions, and during an attack.

Operations in the first of these categories have the basic objective of securing the maximum possible data on the complete electronic environment; on the grand scale, globally; at lower levels, within those areas of interest to any one nation. Depending upon the resources available and the military requirements, special ships, aircraft, and fixed and mobile land Elint facilities are employed, often operating to comprehensive reconnaissance schedules.

This branch of Elint may be termed 'strategic', and in the next three paragraphs the principal categories of information sought and the purposes to which it is applied are briefly discussed.

Ideally, all types of radars (land, sea, or airborne, for surveillance, fire control navigation etc) will be detected, located, and identified by their 'radar signatures' in all their operating modes (eg search, tracking etc), and their transmissions recorded. These recordings, which will contain the radar characteristics such as PRF (pulse repetition frequency) pulse width, transmitter frequency, modulation, etc, which constitute the 'signature' of a radar which enables it to be identified without being seen. Other electronic reconnaissance targets which are given similar attention are, navigation systems, command and telemetry links, and data links.

The information thus obtained is applied in several ways. Firstly, there is the straightforward intelligence function where the recorded signals are analysed for the purpose of establishing the likely function and mode of operation of each individual electronic equipment. This information may also permit an assessment of the equipment's and/or its associated system's performance. This in turn may make possible some evaluation of the state of the art attained by the nation surveyed.

Secondly, the types, numbers, and locations of electronic systems detected will enable an evaluation of the other nations' strength and intentions to be made. Regular monitoring may reveal potential changes in strategy.

Elint and its subsequent analysis will also fulfil a number of 'tactical' functions. Most direct in application is the use of the knowledge of opposing equipment in the development of appropriate ECM and ECCM equipment and procedures. At the tactical level, in war, special Elint missions may be mounted for the purpose of gaining data for use in planning a specific attack. Typical objectives might be the discovery of the number, types and locations of defensive search radars, missiles etc, and the level of activity in the target area, this data to be used in planning the best mode of attack and the ECM and ECCM tactics to be employed.

An extension of this which is typified by the latest American programmes is to employ computers and other sophisticated equipment to provide a very precise correlation between the location of emitters, defined by a variety of geographical reference frames, so that this information can be used for the guidance of air-to-surface weapons of various kinds for "defence suppression" purposes. DME (Distance Measuring Equipment) is one of the principal navigation reference systems under development for this purpose. Additional information will be found on projects such as PELSS (Precision Emitter Location and Strike System), ALSS (Airborne Location and Strike System), and the other reconnaissance aspects which come within the Pave Strike programme; and weapons, such as Maverick and laser-guided munitions, are described in the Air-to-Surface Missiles, and Reconnaissance Systems pages of Section One of this book.

ECM Objectives:

In broad terms, ECM are employed against an opponent's electronic systems with the objectives of denying him the information they provide, and frustrating the operation of opponent's electronic systems which threaten the realisation of the attacker's intentions. The paragraphs which follow contain examples of specific applications of the techniques which are available to achieve this overall objective.

The crew of a bomber aircraft in the course of an attack on a fixed target will be concerned to achieve the following objectives in turn as the attack develops: to avoid detection by enemy surveillance radar for as long as possible; to prevent tracking by radar after detection; to hide, if possible, the probable identity of the target; to prevent acquisition and tracking by artillery and surface-to-air missile radars. The ECM means available for fulfilling these aims consist of jamming systems which are intended to (a) deny the opposing radar any target information, (b) confuse the radar, or (c) constructively deceive it. The various means are further sub-divided into 'active' and 'passive' techniques.

Considering first, active jamming intended to completely neutralise the opposing radar, two main techniques are used, 'spot' or 'barrage' jamming. The former will normally be applied when the parameters of the radar to be jammed are known, and consists of the transmission of continuous noise on the frequency of the victim radar. Here it is necessary to briefly anticipate the description of ECCM which follows, and mention the techniques of rapidly varying the operating frequency of a radar to frustrate spot jamming. Several modes are possible, known variously as 'frequency agile', and 'frequency wild', or 'swept frequency' radars. These developments have in turn led to jammers capable of following the changes in frequency of the victim radar, and 'swept spot' jammers in which the jammer frequency is swept across a band of frequencies covering those of the victim radar.

The other main type of noise jammer is the 'barrage' or broad-band jammer, the output of which is simultaneously radiated across a whole band of the radar spectrum. This method can be more effective against frequency agile radars or in an environment where exact radar transmitting frequencies are not known, but it requires appreciably greater jammer output power to achieve comparable results to a spot jammer on a given victim radar channel. Where a spot jammer might prove effective with an output of 100 watts, a broad-band jammer could require an output of 10 kW.

The next category of active jamming is that known as deception jamming. Here the aim is not to swamp the victim radar with so much noise that the target return cannot be extracted, but to deliberately falsify the indications. This technique may also be used to confuse, by providing sufficient false, but realistic, data to the victim radar as to make extraction of the valid target data impossible. It will immediately be apparent to the reader that active jammers of this type are considerably more sophisticated than the straightforward noise jammers.

The main reason for their greater complexity is that the jammer's performance characteristics need to be more closely matched to those of each type of radar it is desired to counter. There is a need for far more detailed knowledge of the victim radar's performance parameters and modes of operation, both in advance and in the course of actual military missions. The latter requirement has to be met by on-board equipment designed to monitor and analyse the transmissions of the victim radar, while Elint will have furnished the advance data which is needed for the design of the ECM system.

Deception techniques are mostly directed toward either of the two principal elements of target data produced by a radar— range and bearing. In simple terms, the ECM system detects and analyses the illuminating radar's pulses, and having determined PRF etc, transmits on the victim radar's frequency reply pulses of greater amplitude than the normal reflected signal. This series of pulses, being stronger than the genuine target echoes, is then tracked by the radar's range-gate circuits instead of the genuine target echoes. By systematically altering the delay of the ECM-generated pulses, the victim radar produces erroneous range data indicative of a false track for the target. ECM sets of this type are usually referred to as 'range-gate' stealers or 'track-breakers'.

False bearing information is generated by the ECM system transmitting a strong pulse at a point in time when the victim radar's antenna is not pointing at the target. The false echoes, being stronger than the genuine returns, are seen by the radar as the actual target, in much the same way as the 'range-gate' stealer creates a false set of range data. To be effective the ECM system must be provided with means of establishing the victim radar's characteristics, and in particular its scanning pattern and rate.

Combination of the two foregoing techniques can be effected to yield an ECM system capable of generating a number of false targets, the spread and number of which it is hoped will make it impossible to identify the genuine target.

Other active counter measures include the use of decoy devices which can range from simple drones programmed to fly away from the attacking force along the most deceptive flight path, to more complicated devices which incorporate ECM equipment to simulate the electromagnetic signature of an actual attacking aircraft. They may also include their own ECM systems. The benefits to the attacker of such methods accrue from the deception and confusion they create and the overloading of the defensive system that they are capable of inflicting.

The most widely known and used form of passive ECM is that known as 'chaff'. In essence this consists of the dispensing of quantities of radar reflecting material, such as tin-foil, which has been cut to lengths approximately one half wave length at the band of radar frequencies which are of interest. This characteristic ensures a strong radar response, and the spread of large quantities of chaff produces effects which may be used either to conceal the true target or confuse the defending radar.

Although an aircraft attack against a land target has been used as an example, the fundamental ECM techniques described in that situation are also applied (with detail variations) to the majority of the remaining military situations in which opposing electronic systems confront each other.

So far in this discussion, ECM has been considered from the attacker's point of view, but ECM techniques are available, and are used, by the defender also. He too has much to gain by depriving his opponent of as much information as possible, and to this end passive methods of target detection are preferred to active methods (radar) where possible. For instance, the attacker will not know when he has been detected, or the locations of defensive radars if these are inactive. Passive detection systems, which rely upon the information that can be obtained from any electromagnetic radiations emanating from the attacker are widely used. Examples of typical equipments are described in later paragraphs.

Specific sources of radiation from the target which may provide a subject for this form of ECM are the attacker's radars (navigation, search etc), or conventional radio transmissions. The information that can be obtained by the defender by its use includes: warning of the target's presence, its bearing from the ECM detector, and such data as analysis of the recorded target signals yields.

ECCM:

Having set out the broad objectives of ECM, the objectives of ECCM can be simply summarised as those of rendering ineffective ECM, or if this is not possible, either reducing its effects or trying to turn ECM procedures against their users. One other general observation can be made at this stage. ECCM is mostly concerned with *techniques*, which are embodied in the design of electronic systems (eg a surveillance radar), whereas ECM usually requires a separate item of *equipment* which operates in its own right and not as an adjunct to another system.

As has previously been seen, the ultimate objective of most ECM systems is to either deny the opposition the information he seeks, to surround this with so much false data that the true information cannot be extracted, or to supply so much false data that the information handling capacity of the victim system is swamped. In terms of communication theory, all these aims represent varying degrees of degradation of the victim system's signal-to-noise ratio, to the detriment of its signal detection performance.

In the design of electronic systems, such as a radar, certain general basic principles apply when seeking to obtain the optimum desired signal detection probability. High transmitter power, good antenna gain, a narrow system bandwidth, and those means which drive an enemy to the use of a broader jamming bandwidth are all important.

All but the last of these desired qualities will be design objectives, quite apart from ECM considerations, if only to counteract the effects of natural noise. The last, however, represents a major ECCM activity.

Before going on to describe some of these techniques, it will be useful to consider some of the other design objectives in the context of their relationship with certain forms of ECM. Good directional properties in the antenna, and the minimising of side-lobes will reduce the amount of noise entering the system from directions other than that in which the antenna is pointing. This in turn will eliminate or reduce the efforts of jamming which is intended to produce false bearing information. However, any increase in antenna receiver gain obviously increases both signal and jamming equally when directed at the target.

Measures which can be adopted to force the enemy to spread his jamming over a broader bandwidth are based mostly on the various techniques for changing the operating frequency of the radar. These include rapid switching between a number of discrete frequencies, sweeping the frequency and random variations in frequency.

In meeting the challenge of more sophisticated jamming, i.e. that which attempts to obscure the genuine signal by false data having characteristics akin to genuine signals, instead of mere noise, more complex ECCM methods are required.

A fundamental concept upon which a number of such ECCM techniques are based is that of imposing on the transmitted signal some form of coding that will provide a means of positively identifying the returns. Such techniques may also have the additional benefit of making it more difficult for opposing ECM to generate spurious returns which accurately simulate genuine ones. The amplitude, phase and frequency of the transmitted signal may each be modulated according to a variety of coding methods, and the system receiver equipped with appropriate decoding circuitry to permit recognition of return signals. Other receiver techniques which are of use include coherent detectors and cross- and auto-correlation systems.

Each of the several different classes of radars (pulse, CW or Continuous Wave, pulse-doppler, etc) and the various modes of operation have inherent resistance to some forms of ECM, and also lend themselves to one or more specific ECCM techniques. Readers who wish to explore this wide subject more fully are referred to the numerous excellent texts on radar technology.

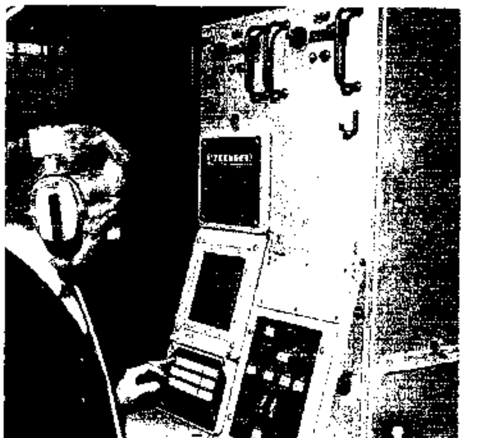
ELINT EQUIPMENT

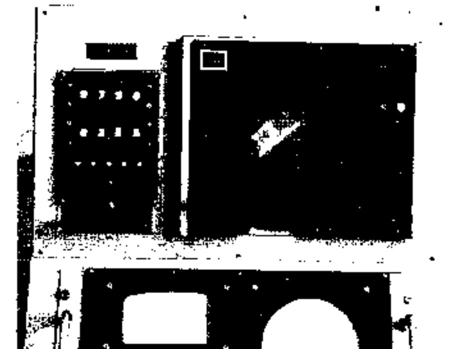
The prime requirements of Elint (Electronic Intelligence) equipment fall into three broad functional categories: detection, monitoring, and analysis. Although operational requirements and other factors will lead to equipment which is designed to take care of one or other specific aspect of Elint, certain desirable general design criteria can be stated. For detection and monitoring, receivers ideally will have the highest possible total bandwidth coverage, coupled with a narrow detection bandwidth for the examination of selected bands of interest in the spectrum. This latter requirement immediately forces a compromise between it and the need to provide sufficient detection bandwidth to ensure the acceptance of enough of the signal bandwidth to permit analysis. Good receiver sensitivity is a further requirement. Another characteristic of importance is that known as 'dwell time'. This may be paraphrased as the time a given receiver needs to look at a signal of interest before it is ready to go on to deal with another signal at a different frequency. This is conditioned by the performance of the logic circuitry used, the scanning methods employed, and recording limitations. The aim is to achieve the lowest attainable dwell time.

Three types of receivers for Elint use can be mentioned. Simplest is the 'wide-open' or video receiver which achieves a broad band response by the use of broadly tuned circuits. Such receivers frequently incorporate little or no logic circuitry, and as there is no frequency conversion, received signals are rapidly and relatively faithfully available for recording. Limitations of the type are lack of sensitivity and poor frequency resolution.

These deficiencies are mitigated in the second type of receiver in which banks of parallel filters,



Operator's console of the SUSIF, Surface Ship Intercept Equipment made by the MEL Equipt. Co. Ltd. The rectangular display presents the complete electromagnetic environment in terms of frequency band and direction of arrival of intercepted signals. More details of this equipment are given in Section Three



A compact EW installation of Decca RDL Series equipment (Entry No **1341.253***) in which the basic direction finder display (upper right) is complemented by additional units for frequency analysis functions*

each bank having progressively narrower pass bands, are linked by IF (Intermediate Frequency) stages in which signals passed through the preceding filter bank are converted down to frequencies lying within the collective pass band of the next bank of filters. As an example, the first stage may consist of three filters capable of passing signals 9-10 GHz, 10-11 GHz and 11-12 GHz, respectively. Therefore if an unknown frequency between 9 and 12 GHz is fed in, it can be determined in which third of this band its frequency lies by recording which of the three filters produces an output. If this output is then 'down converted' and applied to a second bank of filters which have a combined pass band of 1,000 MHz and individual pass bands of 200 MHz, the frequency of the signal can now be established to the nearest 200 MHz. Further converters and filter stages can be added to increase the resolution of the system. Logic circuitry is provided to establish those filters through which a given signal passes, this information being used to provide an indicator readout or printed record. This technique offers advantages of higher sensitivity and frequency resolution compared with the 'wide-open' receiver, but at the price of somewhat increased dwell-time. The latter effect arises since a signal passing through a sequence of filters inhibits those filters (and segments of the spectrum they monitor) until the measurement is completed. Newer technology, such as the use of digital computers to control Elint receivers, offers ways of increasing the speed of operation thereby mitigating the effects of higher dwell time.

The third basic type of Elint, or 'ferret' receiver, is that in which a sharply tuned circuit is manually or automatically swept across the frequency band of interest. Typically, this type of equipment consists of a superhet receiver with provision of accurate, ganged tuning of RF, mixer, and oscillator stages, generally under mechanical or electronic control. Means are also provided for recognition of signals of interest and interruption of the frequency scanning process while these signals are recorded or analysed. Compared with the two previous types of receiver, sensitivity is higher, but data rate is lower. Data rate can be increased by raising the scanning rate, but to the detriment of sensitivity and frequency resolution.

Emitter characteristics of interest for Elint purposes include, carrier frequency, PRF, pulse-width, antenna scan rate, antenna scan pattern, antenna side-lobe pattern, modulation (FM, AM, digital etc), and radars of all types, command links, etc, are the principal objects of attention.

Signal analysis systems and equipment vary considerably in the levels of sophistication employed and in the facilities provided. Some, such as the EMI Electronics Ltd SARIE (Semi-Automatic Radar Identification Equipment), are intended for use with existing direction finding receivers and interfacing with other ships' systems.

SARIE automatically analyses the video-data derived by the receiver from the intercepted radar transmission into a number of parameters, including pulse repetition frequency and pulse width. These parameters, together with certain manually determined data, are then electronically compared with a 'library' of known radar data. The result of the analysis and any identification arising from the comparison are presented on the Alpha-Numeric Display. Facilities can be provided for interfacing the output with a standard ship's teleprinter or Action Computing Centre. Compact, modular design is suitable for installation in new or existing ships, aircraft or other military vehicles with the minimum of modifications.

1379.091
EW DIRECTION FINDERS

In Entry No. **1378.091**, the detection and analysis of enemy electromagnetic radiations was discussed. If this information is to be fully utilised, the geographical locations of the sources must be established. This generally entails the use of direction-finding equipment, which exists in many forms to comply with differing operational requirements. Equipment of this kind is known by several names, most common being 'passive radar', 'RDF-Radio Direction Finding', or 'Intercept systems'. Direction finding techniques also play an important part in ECM and ECCM systems, in addition to their role in Elint operations.

As might be expected from the diversity of direction finding applications implicit in the above, this results in a large number of types of equipment, designed to fulfil specific functions. Land-based systems, for example, will include those for detecting and locating potentially hostile emitters approaching or operating near friendly territory. These emitters may be carried by ships, aircraft or land forces. Other land-based direction

finders may be concerned with surveillance of the electromagnetic environment in 'hostile' territory, as part of the overall Elint programme.

Naval forces require EW direction finders to give warning of opposing ships and aircraft, and in aircraft similar systems are used to locate a potential threat (air search radar, missile tracking radar etc), or a potential target.

Both directional and omni-directional antennas are employed, but the latter are more common, one reason being the unavoidable operational circumstance that the direction of arrival of a signal is not known in advance. Antennae are dealt with in more detail in entry No. **1380.091**.

Directional antennas of one form or another, designed to produce radiation patterns appropriate to overflying or 'sideways-looking' aerial reconnaissance applications, may be used on aircraft, drones, or satellites in support of Elint operations. Location of radiation sources is usually effected by the subsequent correlation of the recorded signals with navigational data, time, and the known characteristics of the antenna. Multiple observation of the emitter, and the use of triangulation plotting techniques, or variants of it, are typical of this method of location.

A type of EW direction finder which most justifies the use of the term 'passive radar' is that in which a directional antenna, rotated at high speed, is connected to a receiver. Such systems are generally employed for the passive detection of hostile radar transmissions, and provide bearing information of the source relative to the receiver. Thus, to some extent, the system operates as a radar without its transmitter. Broad-band provisions are made according to requirements to enable one system to cater for the detection of as many radar bands as possible. These provisions apply to both the antennae and the receiver. A high scanner rotation rate is necessary to increase the probability of reception of the hostile radar illumination. Representative relative rotation speeds are, up to 2-3,000 RPM for the passive radar, and 10-30 RPM for surface search radars. An example of this type of EW direction finder is given in Entry No. **1381.053**. Land, sea, and airborne equipment using this technique are in use.

Fixed antennas of several types also are used for direction finding, mostly relying upon monopulse techniques. To derive directional data by these methods entails more complex signal processing arrangements, and consequently systems of this sort are more usually employed in non-airborne roles, though their use in aircraft is by no means excluded. Ships' EW systems frequently include one or more systems in this category.

Two methods described by Sparagna, Oeh, Huber, and Bullock of GTE Sylvania, Inc (*Microwave Journal*, May 1971), illustrate techniques possible with antenna arrays of two or more conical log spiral elements, and broad-band spirals.

In a three-channel phase and amplitude comparison monopulse system, RF signals are received by each of four such elements and then combined in a beam-forming network to produce azimuth and elevation sum and difference signals simultaneously. The sum of the four element radiation patterns is characterised by a single beam with its maximum on the axis of the array. The difference produces a split beam with its null coincident with the axis of the array, and lobes in anti-phase on each side. Since the phase relationship between sum and difference patterns is in opposition to one side of the axis and in phase on the other side, the sense of signals arriving from left or right of the axis can be determined by phase comparison.

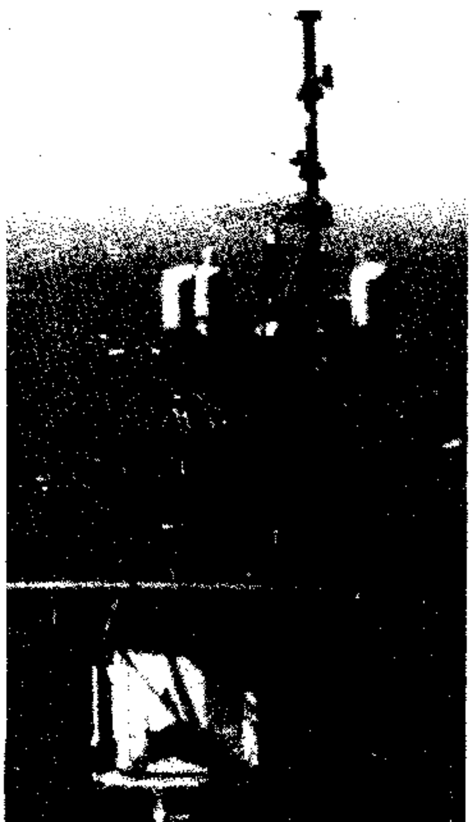
Precise bearing data is obtained by comparison of the amplitudes of the signals amplified in the sum and difference log IF strips, the output voltage difference being proportional to the ratio of the signal strengths received by the sum and difference patterns. The magnitude of this ratio is equated to the angle of arrival of the signal off the array axis.

A typical field of view for an array of this sort is in the region of 30 degrees, and RMS bearing accuracies of 2-3 degrees are quoted.

The other method described is phase comparison monopulse interferometry, in which the differential phase between two antennas is compared to determine the direction of arrival of an incident RF wave front. This defines the angle of arrival in one plane, and another, similar, channel is needed to determine the second co-ordinate angle. While it is essentially true that accuracy of such a system increases as the baseline between antenna elements is increased, this gives rise to ambiguity.

For multi-octave phase interferometry, measurement of frequency is critical in order to resolve phase and angle ambiguities. The multiple wavelength base-line interferometer referred to as the phase/phase technique can be used over several octaves. The antenna separation to wavelength ratio is selected for the interferometer baselines to provide a ratio that permits unambiguous angle determination once the frequency of the signal is measured. Broad-band planar log periodic spiral elements arranged to provide the interferometer baselines over the desired frequency range of the system are used.

Lobe comparison systems, of greater or lesser complexity than those described above, are employed with suitable antennae to fulfil a variety of other operational functions in addition to that of Elint. In aircraft, for instance, Radar Homing And Warning (RHAW) systems which alert the crew to the fact that their aircraft is being illuminated by radar, generally provide an indication of the direction of the threat.



This picture of the upperworks of the USN escort, USS Hepburn, *shows a variety of EW antennas. The three dome-topped housings probably protect 'spinning' aerial DF and intercept equipments for various parts of the RF spectrum, and other aerials can be discerned arranged around the drum-shaped section of the mast. Near the bottom of the picture is another small assembly of eight horn antennas in a group which also may be for microwave direction finding*

1380.091
EW ANTENNAE

Antennae for EW applications are as widely varied as the numerous functions of EW itself and the differing constraints imposed by the requirements of operation from mobile platforms of all types, and fixed bases. Much of antenna design still remains nearer to art than science, which leads to a situation where secrecy concerning new developments is likely to be rewarded by greater dividends than in other areas of military technology which have been more rigidly formulated. For these reasons the following paragraphs contain descriptive notes of examples of those types normally found in EW systems only. Practically all other types find application in one or other area of the overall EW activity, but are treated fully in many textbooks.

As the previous paragraphs on other aspects of EW have indicated, normally conflicting design objectives such as broad-band operation, high gain/sensitivity, good signal-to-noise performance, etc have to be faced. These and similar problems are encountered in EW antenna design.

Pairs of bent dipoles, arranged to form a turnstile array, provide hemi-spherical coverage and circular polarisation. This is a type of antenna commonly met on naval vessels for monitoring purposes, and can often be identified as a symmetrical installation of four tapered 'thimble'-shaped radomes on a flat base-plate.

Log-periodic antennae of various types are widely used, and this form of antenna is valuable for both its broad-band and directional characteristics.

The spiral in its several forms is a particularly useful EW antenna type and has applications on ships and in aircraft. Two or four-arm equi-angular cavity-backed spirals are widely used for the broad band, circularly polarised and good directional properties they exhibit. They are particularly suited to aircraft installation because of their small size and flush mounting possibilities. Spiral elements are frequently used in precision broad-band direction finding systems such as amplitude monopulse, two-channel phase and

Electronic warfare aerials on the mast of a Royal Netherlands Navy ship. Microwave horns can be seen, with an array of four log-periodics

amplitude monopulse, and double-base interferometer arrays.

A related type of antenna is the Archimedes spiral, and this form, allied to a serpentine effect introduced into the spiral, in the Raven AM-139 is stated to permit either smaller physical dimensions for a given performance, or an electrically larger antenna for the same physical dimensions.

Phased arrays of equi-angular spirals are employed to form simultaneous multiple beam DF systems. One array produced by Sylvania Electronic Systems consists of five 'venetian blind' slats each of which carries 16 spiral elements and is capable of being rotated (with the other slats) to increase the gain of the beams off the broadside position.

Matched conical spirals with beam-forming networks can be used to form arrays for monopulse and other direction finding methods, as previously described. Such arrays are more frequently encountered on naval vessels and can often be distinguished by relatively large 'thimble' protective radomes on the superstructure.

In the field of antennae for active ECM purposes, the use of phased arrays to provide beam agility is a subject which is currently receiving considerable attention, but upon which little information is available. So-called multiple beam antenna systems are similarly under energetic development in this context. Stripline techniques, which eliminate the heavy and complex waveguide arrangements previously required, are significant in the development of the latter.

1492.091
ACTIVE ELECTRONIC COUNTER MEASURES

INTRODUCTION:

Within this broad category of Electronic Warfare are contained those systems and equipment which seek to deny an enemy the proper use of his electronic systems by the use of radiation(s) on one's own part. Two main classes of equipment are employed. These are described by their general mode of operation, and are 'noise jammers' and 'deception jammers', respectively. The terms are self explanatory. The former has the objective of injecting sufficient noise into the opposing system (radar, command link, etc) to render it inoperative, while the second is designed to give protection by more subtle means which usually are intended to deceive. This is often achieved by the generation of enough false targets to make it impossible to establish the genuine one, or to produce a single, strong false target for an opposing radar to lock on to while the real target goes untracked.

NOISE JAMMERS:

The principal criterion in the design of noise jammers is the realising of maximum noise-power density at the opposing receiver(s). A jammer transmitter capable of an output of 100 watts and a bandwidth of 10 MHz radiating on one X-band radar frequency would produce a noise-power density of 10 W/MHz. The same output spread over a bandwidth of 1,000 MHz would yield a noise-power density of 0.1 W/MHz.

The former type of jamming corresponds to what is known as spot jamming, and the latter to broad band barrage jamming. Among the ECCM available against the former are the various methods of varying the operating frequency of the subject radar. To meet this, and additional to the broad-band barrage technique, jammers can be made to sweep a band of frequencies, the rate of sweep being optimised to produce the greatest coincidence with the subject radar's frequency usage, or to monitor and follow changes in the subject radar operating frequency. There are thus a number of compromise options available in the design and tactical use of noise jammers.

If sufficient space and prime power can be provided to permit a reasonable noise-power density to be achieved, broad-band barrage jamming is generally preferable, especially in regard to such ECCM as frequency agility which modern microwave devices are making increasingly attractive.

An ALQ-87 ECM pod beneath an F-111A aircraft

A type of ECM system extensively employed by the American air forces in Vietnam is based on the use of pods specially equipped to fulfil one or more ECM roles. The ALQ-71 barrage jamming pod contains sub-systems for noise jamming in the L-, S-, and C-bands of the radar spectrum. The pod weighs about 150 kg, is 3 m long, and 25.4 cm in diameter.

Separate units contain pairs of jammers for each of the three radar bands. The noise signals are radiated by blade antennae, six in all, on the underside of the pod. These provide both horzontally and vertically polarised signals. At least 700 of these ALQ-71 systems have been produced for use on F-4, F105D/F, F-101, T-23, B-57 and RB-66 aircraft, and they are used to give protection against air surveillance radars and surface-to-air missile battery radars.

Another pod system, the ALQ-72, operates in the X-band and is designed to counter airborne intercept radars. Noise signals are radiated from a rear facing horn projecting beneath the pod which weighs 91kg and is 2.5 m long. Over 300 have been produced and it is used on the same aircraft types as the ALQ-71.

Noise jammers used on the B-52 include the ALT-13/28 carcinotron noise jammer, the ALT-16/31 travelling wave tube barrage jammer, and the ALT-15/32. US Navy jammers include the ALQ-31, ALQ-55, ALQ-76, ALQ-78, and ALQ-91, for airborne use, and SLQ-12A, SLQ-17, SLQ-19, and SLQ-21 equipment for shipboard applications.

DECEPTION JAMMERS:

Most deception jammers have the objective of replacing genuine radar target data with information which is false in respect of range or bearing, or both parameters. The basic essentials for this to be achieved are a means of generating a replica of the subject radar's signals at a higher power level, and arrangements for systematically controlling the transmission of the false signal in time, relative to the subject radar's parameters. Those of the latter which are of principal concern are PRF and antenna scanning rate. Thus, it is implicit that the jammer also incorporates certain facilities for the analysis of radar signals reaching the aircraft.

Considering first the generation of false target information in respect of range, a pulse on the correct frequency and of the current waveform, if transmitted 12 micro-seconds after receiving the radar's pulse, will produce an effect at the subject of a target one nautical mile further from the radar than the actual range. If the subject radar's PRF can be accurately and successfully predicted, it is possible to anticipate reception of the pulse at the target and for the jammer to transmit the false reply early, thus producing a false, shorter range indication. This suggests one ECCM, variation of the radar PRF.

To produce false targets at other than the genuine bearing from the subject radar, the antenna scanning rate is determined, and pulses are transmitted by the jammer on a systematic basis when the radar beam is not directed at the real target. Factors determining the efficiency of this type of jamming are the radar antenna sidelobe and gain characteristics, and the power available from the jammer. Range, of course, influences the relative effects of these parameters.

The above remarks apply essentially to the jamming of non-coherent radars. In the case of coherent systems, the jammer must be able to maintain the correct phase and frequency stability relationships with the subject radar for the false reply to be accepted by the radar receiver. Deception jamming is made more difficult by the adoption of pulse-compression, matched filter, and pulse coding techniques. One method of coping with such ECCM is to employ a jammer-repeater, in which instead of attempting to generate a replica of the radar's transmission, the received signals are delayed by a controlled length of time before re-transmission.

Principally, these jamming measures are employed to frustrate surveillance and search radars. For tracking radars different jamming techniques are required.

At its simplest the track-breaker technique involves overlaying the genuine target echo with a false one (when the tracker radar has locked on), increasing the power of the false echo, and then varying the false echo so that as the radar remains locked on to the stronger echo, false target data is generated.

Tracking systems using conical scanning can be jammed by sensing the scan rotation rate, and modulating the false echo at the same frequency. This has the effect of causing the tracking antenna servo system to point the scan in an incorrect direction. The extent and direction of this deflection are dependent on the amplitude of the modulation and its phase relationship with scan rotation.

A more recent concept in the active jamming field, mainly directed towards creating confusion and/or saturation in the opposing radar environment, is that of expendable jammers. This idea has been the subject of substantial research and considerable debate in the USA, and the outcome is not yet clear. Specific proposals which have been made include the 'seeding' of planned areas of operation by numerous jamming transmitters supported by parachutes, and possibly switching them all on simultaneously by command link. Other functions, such as tuning, might also be performed by similar means from a control aircraft.

1497.091
PASSIVE ELECTRONIC COUNTER MEASURES

DESCRIPTION:

Within this category of electronic warfare are those means of combating opposing radars which do not rely upon the use of transmissions. It includes chaff, decoys, radar absorbent materials, and more latterly, the incorporation of certain design features in targets such as aircraft that have no other purpose than to reduce the effective radar cross-section.

Of these, chaff is the oldest, still the most widely employed, and most varied in form and application. Chaff consists of lightweight metallic dipoles of dimensions corresponding to those of dipoles at or around the radar frequencies it is desired to jam. By resonating at these frequencies, when deployed in great numbers, clouds or corridors of chaff produce a very large radar back-scatter cross section. This property is exploited tactically in many ways to counter specific threats, and results in a considerable range of equipment for the deployment of chaff.

Physically chaff is generally of either thin metal foil or a metallised glass or plastic. The latter materials are newer, although metal foil or wire may be used in some instances. Advantages of the more recent substitutes are better dispersion after ejection, lighter weight, and better packing density.

The use of metallised glass fibres, which are of about one mil diameter, permits roughly twice the number of individual dipoles to be packed in a given volume as occupied by aluminium foil. The former material is also more convenient for the longer dipoles which are necessary for countering radars operating in the lower frequency bands, S- and L-bands, for example. Bundles or balls of fibres cut to varying lengths to cover several frequency bands are employed, and these are contained in small cardboard packets which fly open after being ejected from the chaff dispenser. The slipstream then causes each ball to rapidly break up into individual strands over a wide area.

A typical chaff dispensing system used by US forces is the ALE-32 which is capable of ejecting both chaff packets and infra-red flares, the latter as decoys of infra-red homing missiles. One installation of the ALE-32 is in a pod-mounted system in which two ALE-32 dispensers and their magazines (3 per dispenser) are located in a back-to-back configuration. Up to six of these pods could be carried by USN EA-6A ECM aircraft but two is the normal complement. A variety of release programming options is available to the aircraft crew.

Another dispensing technique employed consists of a rocket which is projected ahead of an attacking aircraft to provide protection by creating a chaff cloud between it and the defending radar(s). An example of this is the ADR-8A carried by USAF B-52 bombers, which is fired from the ALE-25 rocket pod.

The ejection system as used in the ALE-32 is electro-mechanical, and other examples of this type are the ALE-24 and ALE-27. The latter is a repackaged version of the former, and both are installed in different models of the B-52. In the B-52 G and H, the ALE-24 consists of four 5-channel ejectors located in each wing of the aircraft, each ejector being capable of releasing 10 packets of chaff per second. In B-52 C to F models, the ALE-27 installation comprises four ejectors on each side of the rear fuselage.

Alternative ejection methods include pneumatic and pyrotechnic. The ALE-28, used in the F-111, is of the former type and uses compressed nitrogen to expel chaff packages from dispensers housed in the rear of the fuselage. Each dispenser has two independent magazines under the control of a remote timing and control unit in the cockpit. The ALE-29A has two separate dispensers, each having 30 launcher tubes for individual packets of chaff. These are ejected by electrically fired impulse cartridges. Firing can be programmed to permit bursts, or salvoes, of packets of varying sizes to be fired at various intervals on an automatic basis. The ALE-29A was initially developed for carrier-borne aircraft.

The uses of chaff for the defence of naval forces, especially from radar homing missile threats, are a subject of considerable study. In this context there is a potential advantage over the aircraft uses of chaff in that the far smaller ratio of target speed to chaff cloud speed in the surface ship case renders discrimination between the two on this basis far more difficult. Depending upon tactical requirements and the resources available, chaff could be dispensed from aircraft or helicopters, but in addition to these methods, ways of making surface vessels self-sufficient in this respect are under examination. One technique, which has been used on the USS *New Jersey* is an adaptation of the Zuni rocket, which is used to carry a chaff payload some kilometres from the ship before dispersing the chaff by explosive means. There is also a requirement for shorter range rockets or mortars which would be capable of rapid and accurate response to meet the threat of low-altitude anti-ship missiles.

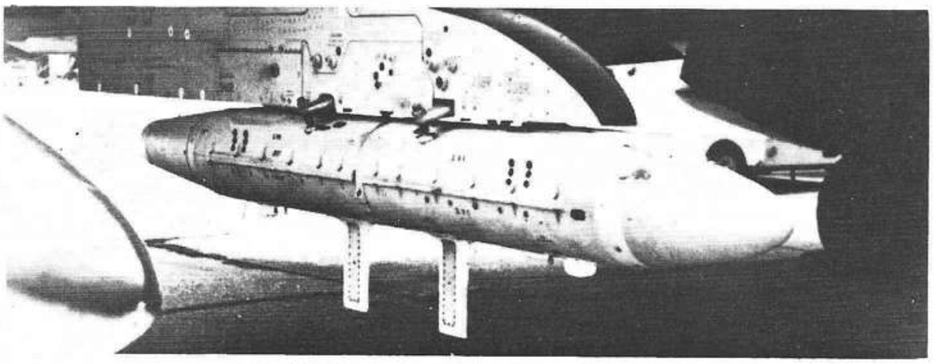
A variety of devices based on similar principles to those of chaff technology have been developed by USA as 'penetration aids' for ballistic missiles, with the objective of confusing detection and tracking radar systems. Some are identical or similar to those used in conventional airborne

This photograph taken from an RN Phantom of a Soviet Badger bomber shows what is probably a passive tail warning blister above the gunner's position applications, such as metallised glass fibres, while others are specifically for outer atmosphere use.

An example of this class, and which is probably intendedfor more sophisticated usage, is a dielectric rod on which are wound bands of radar reflecting material in a form which suggests the intention of creating the radar signature of a much larger body (warhead, for example). Their construction indicates the possibility that they are projected from either the missile booster or the warhead on a systematic basis to create a number of realistic tracks from which it is difficult or impossible to discern the genuine warhead.

In the overall anti-radar activity, work on radar energy absorbing materials has been in progress for a long period and is continuing. Although such materials have proved valuable in such applications as linings for radar anechoic test chambers and other scientific or engineering applications, widespread use in the operational military environment appears still to lie in the future. While an appreciable body of knowledge has been acquired in respect of particle size and distribution necessary in radar absorbent materials, combining these requirements with the mechanical properties required in aircraft, for example, remains a difficult problem. Still more sophisticated, electrical, means of absorbing incident radar energy are being explored, but details are too scarce to permit a useful account in the present volume.

EA-6B aircraft of USN Tactical Electronics Squadron 129 (VAQ-129), showing ALQ-99 ECM pods and fin-top housing for ECM receivers. Each pod contains two jamming transmitters and a receiver; the fin housing contains six antennas and a receiver. Antenna for ALQ-100 deception jammer projects from left wing



ALQ-87 ECM pod beneath wing of F-4 aircraft

1643.091
AMERICAN ELECTRONIC WARFARE PROJECTS

GENERAL:

Each of the US Services has Elint responsibilities, and in addition there are similar facilities operated by other US Government agencies. The USAF, USN, and US Army each carry out airborne Elint operations, and all three operate ground based installations for data gathering and analysis. Ferret satellites are another source of Elint, and the USN has an effective force of electronic intelligence ships, which though numerically smaller than the Soviet equivalent, is highly active and effective. Throughout the world the USA maintains numerous "special communications" installations, both large and small, supported by comprehensive communications networks for the exchange and transmittal of either 'raw' or analysed information to users. Drones and remotely piloted vehicles are increasingly being employed for EW operations in each of the main operational categories—Elint, active counter-measures, and passive counter-measures. The most recent project being the Compass Cope programme.

The scale and efficacy of these varied EW activities can only be surmised from occasional items of authentic information that reach the public domain at infrequent intervals. American trade and technical journals have been able to publish more information concerning the performance of certain Soviet airborne radars than they are able to provide on the physical construction or appearance of these equipments. The almost inescapable conclusion is that these journals have been given some of the fruits of Elint operations, since few journalists, of any nationality, are likely to have either the equipment or the opportunities to gather data such as operating frequencies, pulse-length, PRF, scan patterns etc of Soviet military aircraft radars.

Occasional indications of this type give some slight insight to the importance of Electronic Warfare in the overall military environment. The following list of known US EW projects, and the EW equipment lists in Section Four of this edition are included to assist the reader in his own researches.

AGTELIS:

This is a US Army design project for an automatic ground transportable emitter location and direction finding system. The contractor is Bunker-Ramo, and a contract valued at about $8.5 million was announced in June 1974.

Big Look:

This is a US Navy system for bulk gathering of electronic intelligence data using EC-121M aircraft. These aircraft have been operating in most parts of the world for many years. They will be replaced progressively with EP-3E Orion Elint aircraft.

Big Team:

USAF designation for ten special purpose RC-135C aircraft used by Strategic Air Command in late 1960s.

Black Crow:

USAF code name for a system of detecting vehicles in South East Asia battle areas by means of the RF energy emitted by their ignition systems. All AC-130 gunship aircraft in that theatre were equipped with the Black Crow sensor, which has since been considered as the basis of systems for gathering more sophisticated intelligence by the same method. (See RINT).

Cefirm Leader:

This is a US Army programme providing for battlefield airborne direction finding and jamming of enemy communications systems. It was formerly called project Crazy Dog, and was initiated in the late 1960s. The aircraft employed is the Beech RU-21 and equipment contractors include McDonnell Douglas Electronics Company.

Cefirm Lion:

A similar project to Cefirm Leader (qv), but with different frequency coverage.

Cefirm Scavenger:

This is a US Army project study to provide Beech RU-21 aircraft with the means of communications code breaking.

Cefly Lancer:

This US Army programme was revealed in early 1972. It was planned to use a modified Beech RU-21 aircraft to gather enemy signals information and relay this data to a ground station. It has been reported that the aircraft will be 'minimally manned', which is understood to mean that in normal operation the route will be followed under pre-programmed automatic control, but with provision for manual over-ride and return to base in the event of an emergency.

Charger Blue:

A US Navy programme under which the frequency coverage of USN aircraft ECM equipment is being extended to cater for the use of new frequencies by Soviet radar and missile systems. Equipment employed includes the ALR-45 and ALR-50 receivers and analysis sets, and the ALQ-126 deception jammer.

Combat Angel:

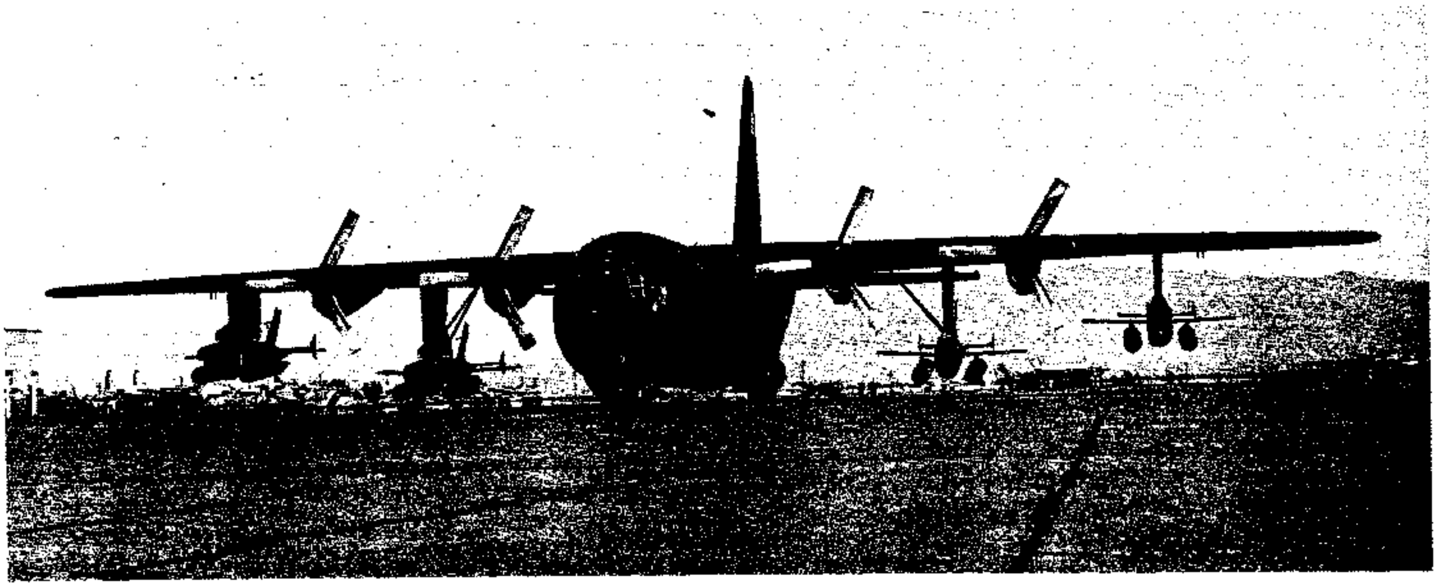
USAF project to use Teledyne Ryan Aeronautical Model 147 drones to precede a bomber force to disperse chaff as a counter-measure to ground air defence radars. Each drone carries two underwing pods containing ALE-2 chaff dispensers, and a later development is the replacement of the older dispenser by the ALE-38 which can carry between 110 and 160 kg of rolled chaff. Employed in South East Asia. The drones are air-launched from special C-130 aircraft and are recovered in mid-air by helicopter or aircraft. Drone flight path is normally pre-programmed. In the latter half of 1973 it was announced that 57 Combat Angel drones operated by Tactical Air Command were to be modified for use as temporary replacements for EB-66 electronic warfare aircraft due for retirement. The normally air-launched drones were adapted for rocket assisted ground launching. Other modifications include the installation of internal jammers.

Combat Dawn:

USAF signal collection system using a Teledyne Ryan Aeronautical 147TF drone. Used in South East Asia and possibly further afield in the Far East.

Combat Look:

A USAF programme by which four RC-130A



DC-130A aircraft loaded with four Model 147 drones, each carrying two ALE-2 chaff dispenser pods

aircraft were modified and provided with equipment for radar mapping duties in South East Asia. Probably operational from late 1967.

Combat Scent:
USAF programme involving the equipping of a number of special-purpose RC-135U aircraft for Strategic Air Command. Programme believed to have been initiated in 1970-71, and probably now operational.

Compass Cope:
A USAF project under which Boeing and Teledyne Ryan are developing competitive long-endurance, high-altitude drones for multiple reconnaissance and Elint operations.

Compass Dart:
USAF programme for electronic direction finding.

Compass Dawn:
USAF programme for electronic direction finding.

Compass Dwell:
A USAF project under which Martin Marietta is developing a piston-engined drone for Elint and photo-recce missions.

Compass Ghost:
A USAF research and development programme of investigation into electro-optical countermeasures for tactical aircraft.

Compass Matrix:
Project to achieve more flexible and efficient use of the jamming capabilities of the ALQ-119 pods carried by USAF F-4 fighter bombers through the use of a computer to control the energy management of the jammer outputs.

Compass Quick:
An equipment and system improvement programme for USAF C-135 Elint aircraft.

Compass Strike:
USAF system of direction-finding using TOA (Time of Arrival) technique for location of hostile radars by computer-equipped F-4 aircraft.

Constant Angels:
A USAF project to carry low-cost, expendable ECM drones beneath the wings of strike aircraft for launch when in the combat area to provide deception and active jamming of defence radars. Studies were planned to start in the latter half of 1972.

Coronet Organ:
USAF study programme for improved methods of employing existing ECM systems. it includes use of Combat Angel drones, flying either pre-programmed or remote controlled flight paths, and specially equipped jamming aircraft.

DTPEWS:
Design To Price Electronic Warfare Suites. Under this programme a family of EW equipment ranging from threat warning systems to passive surveillance equipment and deception electronic counter-measures, of modular design, will be developed to permit EW suites appropriate to various classes of USN ship to be assembled with maximum commonality and minimum cost. The activity is a follow-on to Shortstop. A total of 293 new and existing ships are planned to be fitted. All will have a threat warning capability; a wide area surveillance capability in 175 ships; and an ECM capability in about 60 ships.

EF-IIIA:
Electronic Warfare version of F-111A. One of eleven projects in the Pave Strike programme for enhanced strike capability and defence suppression for the USAF.

ERASE:
Electronic Radiation Source Eliminator. This is a US Navy research and development programme devoted to advanced anti-radiation missile technology.

EP-3E Aircraft:
A number of Lockheed Orion anti-submarine aircraft (seven P-3A and two P-3B) are being modified for electronic surveillance duties, in which role they carry the designation EP-3E. These will be deployed on a world-wide basis to replace EC-121M aircraft. Changes in the Orion aircraft include use of Allison T-56-A-14 engines, as in the P-3C; strengthened wings and landing gear; and a modified fuselage. Take-off weight has been increased to 64,400 kg. Three large radomes, two ventral and one dorsal, give the EP-3E a characteristic appearance; the lower two presumably house scanners for passive search and direction finding, and it is possible that the forward unit also has an active radar capability. The upper radome will house special broad band-receiver antenna arrays. There are also numerous fixed antennas for Sigint data collection.

EV-1:
In May 1974 the US Army announced plans to modify a number of OV-1 reconnaissance aircraft to equip them for Elint duties. The new designation is EV-1. There is a possibility of Israel evaluating the EV-1 and acquiring a number of these aircraft.

Le Faire Vite:
This colloquially named project is a US Army programme for the provision of a sophisticated and extensive Elint facility in Europe to accept and process what radio and radar data can be gathered from adjoining Warsaw Pact countries. Collection methods are likely to involve both airborne and ground-based systems. The only information concerning the location of Le Faire Vite is that it will be based in West Germany. Harris Radiation Systems was awarded a $9.5 million contract in January 1972.

MEWS:
Microwave Electronic Warfare System. A US Navy development programme under which Texas Instruments is producing a phased array jamming equipment for USN aircraft.

PELSS:
PELSS—Precision Emitter Location and Strike System—is an $86 million programme with the objective of devising a method of locating opposing radar emitters by means of TOA (Time-of-Arrival) techniques. One of the eleven major projects of the Pave Strike programme.

Quick Fix:
This is a US Army programme to provide a helicopter-borne communications intelligence collection capability. The major contractor is the United Technology Laboratory and the project had reached the test phase by early 1972.

Quick Look 1:
This code name refers to a US Army Elint system that employs Mohawk OV-1C aircraft equipped with the APQ-142 electronic intelligence receiving system flying missions parallel to the European NATO/Warsaw Pact boundary line for the gathering of radar activity data. The equipment is thought to cover a band extending from the UHF region up to J-band, and to be capable of providing emitter locating facilities. It is housed in two large pods carried on outboard wing station mounts. The APQ-142 is produced by United Technology Laboratory.

Quick Look 2:
Quick Look 2 is the designation of a US Army study for an improved version of Quick Look 1, and which will be carried by the OV-1D aircraft. The Litton ASN-86 inertial navigator fitted to this aircraft provides potential for improved emitter location accuracies, and other improvements would include provisions for on-board analysis or ground relay of intercepted radar signals. The contractor is HRB Singer.

RINT:
RINT—Radiation Intelligence is the term given to methods being examined for the gathering of intelligence data by detection and analysis of spurious RF radiation from enemy systems and equipment. Potential sources include: motor transport, power generation and supply equipment, radar when working into a dummy load, electro-mechanical communications equipment, power lines etc. The US DoD, USAF and a number of manufacturers are engaged in studies of this technique.

Rivet Ace:
This is the sixth and latest in a series of ECM updating programmes for USAF Strategic Air Command B-52 bomber aircraft. Equipment involved includes the ALQ-117 combined noise and deception jammer: ALQ-122 'smart noise equipment', developed by Motorola under the Quick Reaction Contract (QRC) 496; ALQ-127 active tail warning radar; and QRC-515 improved ALT-28 jammer.

Rivet Card:
A USAF programme of the late 1960s under which six special purpose RC-135M aircraft were outfitted for Strategic Air Command.

Rivet Quick:
A USAF programme under which a number of special purpose RC-135M aircraft were equipped

for Strategic Air Command in 1968.

Rivet Top:
Under this USAF project of the late 1960s a number of EC-121 aircraft were equipped with an automatic data relay system for the transmission of ground sensor data back to a ground analysis station. Deployed in South East Asia.

See Saw:
US Navy airborne electronic warfare project.

Senior Book:
A USAF programme for gathering Elint data using U-2 high-altitude reconnaissance aircraft.

Shortstop:
US Navy ship-borne EW system, AN/SLQ-27. Two systems had been produced by ITT and had entered evaluation trials by early 1972. System combines a multi-band antenna array, several receivers, a threat evaluation sub-system, and counter-measure equipment. Equipment includes a Sylvania antenna, the SLQ-17 deception repeater jammer, and WLR-8 spectrum scanner and analysis receiver. Shortstop was developed for use on carriers, missile frigates and destroyers. The project was cancelled because of unacceptable costs, and the successor programme is the Design To Price Electronic Warfare Programme.

TAREWS:
Tactical Air Reconnaissance and Electronic Warfare Support. USAF photographic/Elint/ECM drone study project.

TASES:
Tactical Airborne Signal Exploitation System. This is a US Navy project with the aim of providing a successor system for the carrier-borne EA-3B, land-based 'Big Look' EC-121 aircraft, and later the interim EP-3E (qv) Elint aircraft. The system will be carried on an aircraft yet to be chosen and will be used for long-range Elint missions to provide detection, location, signal collection, and automatic analysis of emitters. In February 1973 it was reported that the two principal candidate aircraft are the S-3A Viking and the EA-6B. TASES-equipped aircraft would detect radar signals of unknown ships at long range, determine their direction, perform some signal classification and relay real-time data back to surface ships.

TEDS:
Tactical Electronic Decoy System for simulating strike aircraft to draw the fire of enemy surface-to-air missiles. The USAF originally proposed that the decoys would carry jamming equipment and target augmentation devices, and have adequate performance to simulate high-performance aircraft, but subsequent to the 1973 Middle East conflict, reconsideration suggested a less complex and cheaper type of vehicle.

TEREC:
Tactical Electronic Reconnaissance. Extended spectrum, high accuracy Elint system under development for USAF F-4C.

TEWS:
Tactical Electronic Warfare System. Internal EW suite for F-15 aircraft, and comprising Loral ALR-56 radar warning receiver, Hallicrafters

Teledyne Ryan Model 147 drone with ALE-2 chaff dispenser pods

ALQ-135(V) counter measures set, and Magnavox ALQ-128 warning receiver.

Tree Cat:
US Navy phased array jammer equipment under development by Maxson Electronics.

Tree Moth:
US Navy noise jammer released by parachute from an aircraft or drone and capable of radiating 1 kW of noise in the S-band during a descent time of about 10 minutes. USN tests of the system, which was developed by Bowmar/TIC, were carried out in the last quarter of 1973.

Wild Weasel:
The Wild Weasel code name is applied to USAF ECM-equipped aircraft and their operations against opposing air defence and missile guidance radars, in support of strike and bomber aircraft. A small number of the specially equipped Wild Weasel aircraft accompany the larger force of strike aircraft with the objective of providing protection for the latter by co-ordinated jamming operations of all kinds (deception, spot, barrage etc) to reduce the effectiveness of anti-aircraft defences. Wild Weasel operations were carried out in South East Asia since 1966 at least, and the overall designation covers a variety of aircraft, equipment, and operational techniques.

Initially, the primary platform was the F-105F Thunderchief aircraft, carrying an Electronic Warfare Officer to operate the ECM systems, one of these aircraft accompanying other fighter-bombers on strike missions. A number of RB-66 tactical bombers were also employed. More recently, in the USAF attacks on North Vietnam in April, 1972, EB-66 and F-105G Wild Weasel aircraft were used to jam 'Cake' series height-finding radars and Fan Song B guidance and control radars. Hardware included in Wild Weasel installations includes AN/APR-25, -26, -35, -36, -37, and -38 ECM sets. A number of F-4D aircraft are to be fitted with an advanced Wild Weasel installation.

466L:
The USAF 466L programme is a world-wide network for the collection, processing, distribution and transmission of electronic intelligence data to a variety of user organisations, including the US Forces. Data gathered is understood to include communications traffic, satellite transmissions, navigation signals, and certain radar transmissions. Site locations that have been named include Turkey, Pakistan (Bada Beir), Clark Air Force Base (Philippines), Japan, Alaska, and Australia. The Pakistan site was dismantled several years ago, and there is some doubt that the Australian installation is associated with 466L.

Few details of equipment have been obtained, but the ITT FLR-12 passive receiver antenna system and the Sylvania FLR-9 are used.

438L:
Under the 438L designation the USAF set up an intelligence data handling system (AIDS— Auto Intelligence Data System) for the high speed processing of information gathered on a world-wide basis. The system was subsequently transferred from the USAF to the Defence Intelligence Agency thereby making the 438L nomenclature redundant. It has not been confirmed that this system deals with actual electronic signals intercepted from foreign transmitting equipment, and it is possible that its function is to process written and other forms of intelligence data.

1644.091
SOVIET ELECTRONIC WARFARE

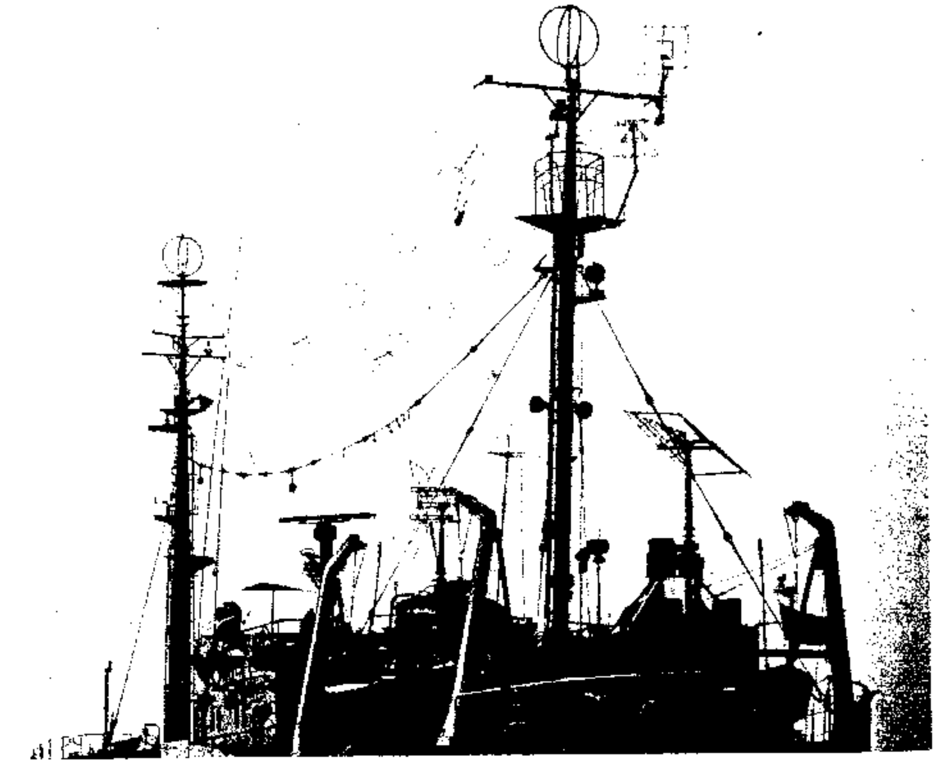
General:
Evidence of Soviet EW activities, in detail at least, is even more scanty than that of comparable American operations, but what there is points clearly to a full appreciation and considerable skill in the use of EW techniques. The specially equipped Russian 'trawlers' which can usually be found in the neighbourhood of foreign forces whenever anything of interest is happening, are a well-known example of Soviet Elint at work. There is a fleet of over 50 Soviet surveillance ships. Almost equally widely recognised are the naval vessels that accompany NATO forces on their exercises, and the Soviet aircraft that probe land defence systems and shadow shipping.

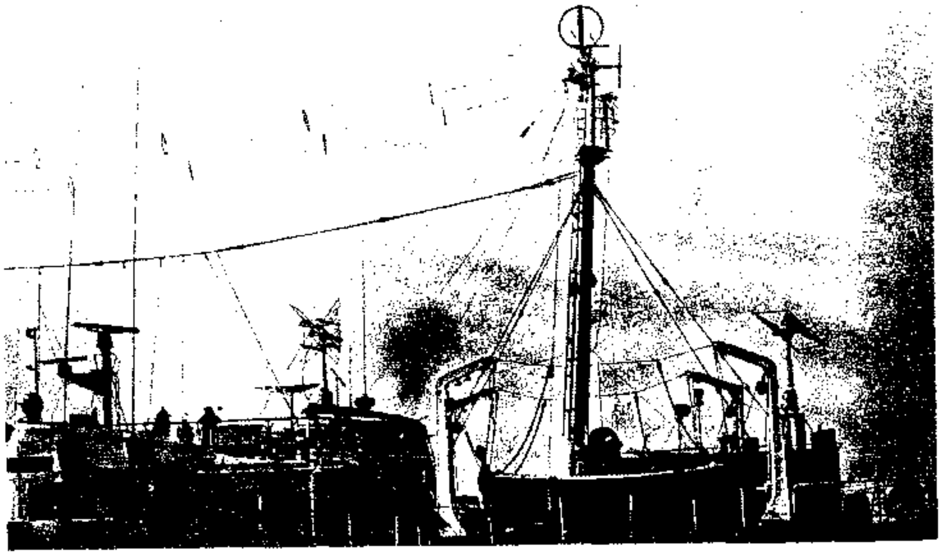
Other significant indications are such difficult to conceal objects as EW antenna arrays on ships of the Soviet fleet, which items of hardware handsomely outnumber their counterparts on Western vessels. The large number of Cosmos series satellites includes so many which are not photographic reconnaissance vehicles, scientific, or other identifiable missions, that a considerable ferret satellite population is a fairly safe assumption.

Most of the other evidence of Soviet EW activity is only directly obtainable by military authorities in the West, and how much of this becomes public is a matter of accident or design on the part of those who reveal morsels of what has been discovered.

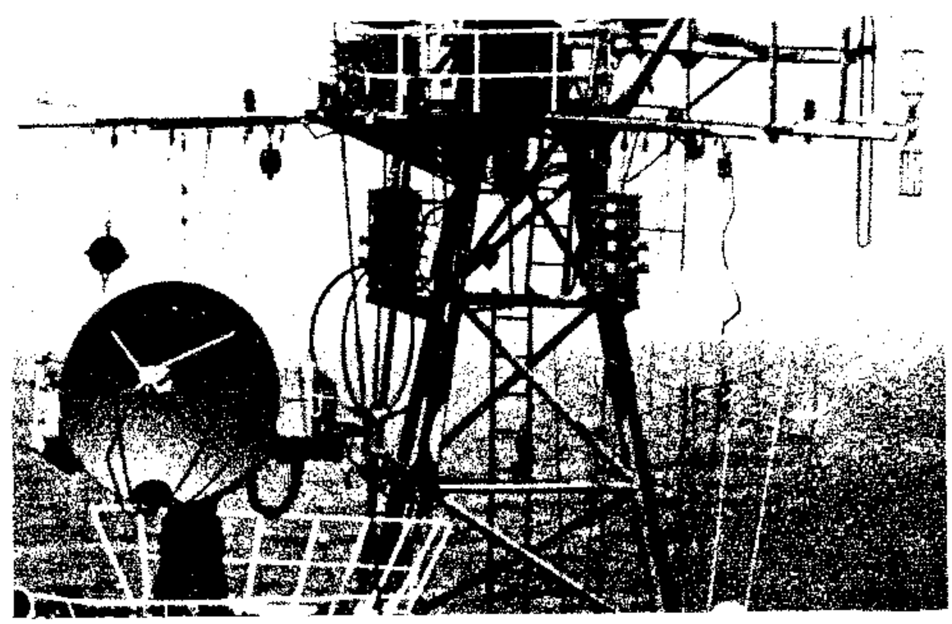
Sources of this nature have yielded such uncorroborated, but reasonable, facts as: sophisticated use of chaff to obscure air transport movements at the time of the large-scale movement of forces into Czechoslovakia in 1968; passive tracking of US Navy ships in the Mediterranean by night and without using active radar; the use of spot and barrage noise jammers capable of 1 kW in aircraft; use of deception repeater jammers in bomber aircraft; the incorporation of elaborate ECCM in missile guidance and other radars, and the use of ground-based jammers to frustrate radiation homing air-to-surface weapons. The existence of a land-based radio direction finding network, designated 'Krug', has also been reported, and this is said to be used for the location of surface ships at ranges of about 10,000 km and for the direction of maritime reconnaissance aircraft. In November 1972, General Sir Walter Walker, when addressing the Military Committee of the North Atlantic Assembly in Bonn, said the Soviet EW capability had shown a "startling increase" in the two previous years, and went on to warn that on the NATO northern flank the Soviet forces "can neutralise our ship-to-ship tactical networks, our early warning radars, our weapon control systems, and our battlefield communications."

The inadequacy of this information makes it impossible to attempt any quantitative or qualita tive analysis of Soviet EW capabilities, but in general similar sums of money to those spent by the USA can be expected to be devoted to EW by the Soviet Union, and the same relationship between the technologies of the two major powers as obtains in other areas of military equipment, probably applies also.





The two photographs of a Soviet Elint monitoring ship, taken in the Baltic recently, reveal the elaborate arrays of antennae fitted. Several types of direction finding loops, four directional broad-band log-periodic arrays, and many others can be identified



The two cylindrical shaped antenna arrays on the lattice mast of this Soviet Navy Petya Class escort are probably microwave detection and direction finding systems. Radar to left is Owl/Hawk Screech fire control radar for guns

SECTION TWO – PLATFORMS

ARMOURED FIGHTING VEHICLES

AUSTRIA

2015.102
AUSTRIAN MEDIUM TANKS

DESCRIPTION

Main tank forces of the Austrian Army comprise some 150 M-47 (**5046.102**) and 120 M-60 (**5024.102**) medium tanks. There are also some 40 M-41 light tanks.

It has been reported that an experimental substitution of an M60 A1 engine in an M47 tank has been made. It is understood that if this proves to be satisfactory after evaluation some or all of the M-47 tank force will be so modified. The modification involves both raising and modifying the rear deck of the tank.

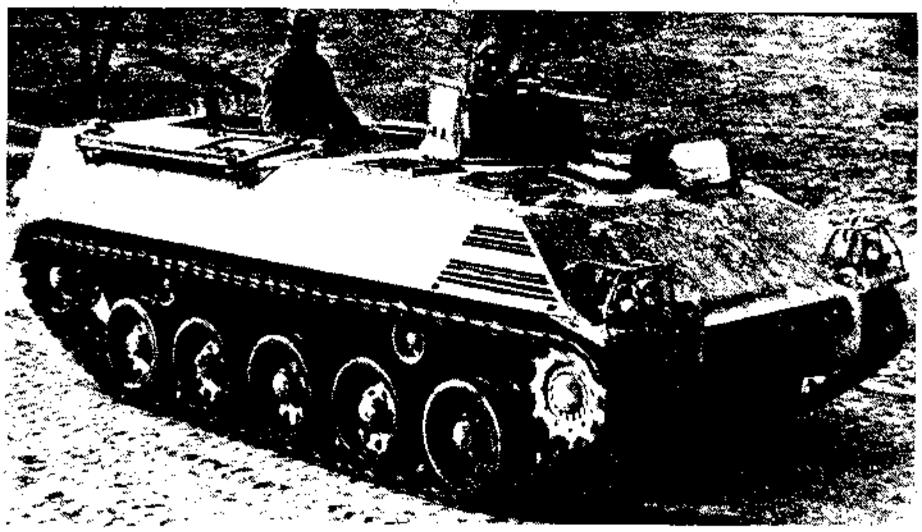
5075.102
SAURER SCHUTZENPANZER SPz-G 4K3F

DESCRIPTION:

One of a family of armoured personnel carriers developed by Osterreichische Saurer-Werke, the SPz-G1 4K3F is currently the standard carrier in use by the Austrian forces.

The chassis of this vehicle has also been used, in modified form, in the Panzerjäger 'K' SP anti-tank gun (**5032.102**). In its unmodified form it has a front-sprocket drive from a Saurer 200 b.h.p. diesel engine (or from a Saurer 4F 220 b.h.p. engine, in which case the vehicle designation is 4K4F) and a hull designed to accommodate a driver and 9 infantrymen. Provision is made for mounting a 12.7 mm machine gun or a 20 mm turret-mounted cannon: the vehicle has also been fitted experimentally with twin 80 mm rocket launchers.

Variants of the basic design include artillery control vehicles (SPz-Fü A1 and SPz-Fü A4), AA control vehicle (SPz-FüFla), mortar carriers (SPz-GrW1 and SPz-GrW2), radio vehicles (SPz-Fü 1 and SPz-Fü 2), teleprinter vehicle (SPz-FS) and ambulance (SPz-San).



Saurer Schützenpanzer—APC version with machine gun

CHARACTERISTICS:

Crew: 10 (driver plus 9 infantrymen).
Weight: 12.5 tonnes (laden)
Size: Height 1.65 m (excluding MG etc). Length 5.4 m Width 2.5 m.
Road Speed & Range: 60 km/h/350 km.
Armament: Provision for 12.7 mm MG or 20 mm cannon
Engine: Saurer 200 b.h.p. (3F) or 250 b.h.p. (4F).
Agility: Ground pressure 0.5 kg/sq cm. Max step 0.8 m. Max trench 2.1 m. Max gradient 80%. Ground clearance 0.42 m.
Water-crossing: Unprepared wading to 1.0 m.

DEVELOPMENT:

Sequential development by Saurer. Development of the earliest version (3K3H) started in 1956.

STATUS:

In service only with the Austrian Army, where more than 400 of various versions are in use.

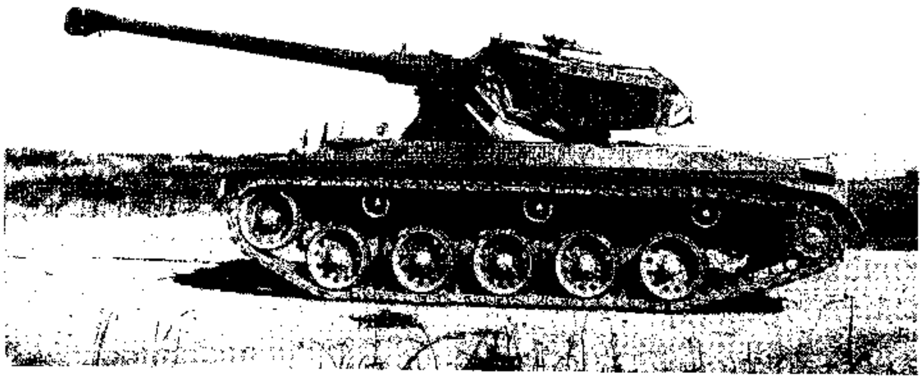
MANUFACTURERS:

Osterreichische Saurer-Werke AG, Vienna, Austria. (taken over by Steyr-Daimler Puch in 1970)

5032.102
SELF-PROPELLED ANTI-TANK GUN PANZERJAGER 'K'

Development of this weapon was initiated in 1965 to provide the Austrian Army with an anti-tank weapon independent of those mounted on their M47 and M60 tanks. The development involved mounting the French FL-12 turret (**2148.103**) and 105 mm gun on the chassis of the Saurer 4K Armoured Personnel Carrier.

The gun used is the French D 1504 (**2147.103**) which fires a spin-stabilised hollow charge shell with a range of 2,000 m and a muzzle velocity of 800 m/sec. The FL-12 turret used on this vehicle and on one version of the French AMX 13 tank (**5020.102**) is of the 'oscillating' type, permitting the use of a semi-automatic loading mechanism with two ammunition magazines, each holding six rounds, in the rear turret overhang. This system enables the crew to be reduced to three, and permits a high rate of fire for the first twelve rounds after which the magazines must be replenished. The modifications to the chassis have been quite extensive, these have included moving the engine and transmission to the rear, the drive sprocket now being at the rear, the suspension has been modified and there are now three return rollers, the armoured personnel carrier having only two.



Panzerjager 'K' with 105 mm gun in 'oscillating' turret

CHARACTERISTICS:

Crew: 3 (Commander, gunner, driver)
Weight: 17 tonnes (laden)
Size: Length 7.78 m (gun forward), 5.58 m (hull only) Height 2.355 m Width 2.50 m.
Road Speed: 65 km/h **Range**: 530 km.
Main Armament: French 105 mm QF gun.
Method of ranging: Commander's estimate. A laser rangefinder is under development. An infra-red/white light searchlight can be fitted.
Max anti-tank range of main armament: 2,500 m.
Ammunition type: Spin-stabilised HEAT, HE and smoke. 26 rounds carried
Secondary armament: Coaxial 7.62 mm MG.
Turret rotation: 360° powered traverse.
Gun elevation limits: $-6°$ to $+13°$
Engine: Steyr Model 6FA 6 cylinder diesel developing 300 hp at 2300 rpm.
Transmission: Mechanical manual gearbox type ZF 655, with five forward and one reverse gears. Single plate clutch.
Agility: Ground pressure 0.75 kg/sq cm. Max step .8 m. Max trench 2.40 m. Max gradient 70%. Ground clearance .40 m. Power-to-weight ratio 17.8 bhp per tonne.
Water crossing ability: Unprepared wading to 1.0 m.

STATUS:

Five prototypes have been built and these have undergone extensive trials. An early production order is expected.

MANUFACTURERS:

Steyr Daimler-Puch (who took over Osterreichische Saurer-Werke AG in 1970)

BELGIUM

FN 4 RM62 in mortar version with 60 mm mortar and twin 7.62 machine guns

5058.102
FN4 RM62 LIGHT ARMOURED CAR

DESCRIPTION:

The FN 4 RM62 has been produced for the Belgian gendarmerie in two versions; first, in a gun version, equipped with a 90 mm gun; second, in a mortar version, carrying a 60 mm mortar and twin 7.62 mm FN machine guns. An army troop carrier version to carry 9 men (including the driver) has also been built as a prototype only.

CHARACTERISTICS (both versions unless stated):

Crew: 3 (Commander/loader, gunner, driver)
Weight: Gun version 8.8 t. Mortar version 8.0 t.
Size: Height 2.52 m. Length (hull) 4.5 m. Width 2.26 m.
Road Speed/Range: 110 km/h/550 km
Main Armament: 90 mm CATI gun or 60 mm mortar
Method of Ranging: Commander's estimate
Rounds carried: For gun 40 rounds mixed HEAT and anti-personnel. For mortar 46 rounds
Secondary armament: Gun version: 1 co-axial one roof mounted AA 7.62 mm MG. Mortar version: Twin 7.62 mm MG's that can be elevated independent of mortar
Turret rotation: 360°, electrically assisted hand traverse at two speeds, fast or slow
Engine: FN 652 6 cylinder petrol engine of 4.74 litres. 130 bhp at 3,500 rpm
Transmission: Single plate dry clutch, synchromesh gearbox with 4 forward and 1 reverse gears

STATUS:

Production was completed in 1971. A total of 62 were delivered to the Belgian Gendarmerie.

MANUFACTURER:

Fabrique Nationale Herstal S.A. (FN), Herstal, Belgium

FN 4 RM62 in gun version with 90 mm gun

BRAZIL

2028.102
BRAZILIAN ARMOURED VEHICLES

DESCRIPTION:

In recent years Brazil has developed a number of AFVs, the first of these being the Cutia-Vete T1 A1 (**5100.102**). The two more recent vehicles are the EE-9 Cascavel armoured car (**5101.102**) and the EE-11 Urutu armoured personnel carrier (**5102.102**). Both the EE-9 and EE-11 have good export potential.

5100.102
CUTIA-VETE T1 A1

DESCRIPTION:

Design of this vehicle commenced in 1966 and by 1972 about 100 had been built. The Cutia-Vete T1 A1 is probably used as a reconnaissance vehicle or personnel carrier.

CHARACTERISTICS:

Crew: 4
Weight: 2.72 tonnes (laden)
Size: Length 3.66 m. Height 1.0 m. Width 1.83 m.
Road speed/Range: 80 km/hr/370 km
Armament: 1 7.62 mm MG
Engine: Four cylinder petrol

STATUS:

In service with the Brazilian Army

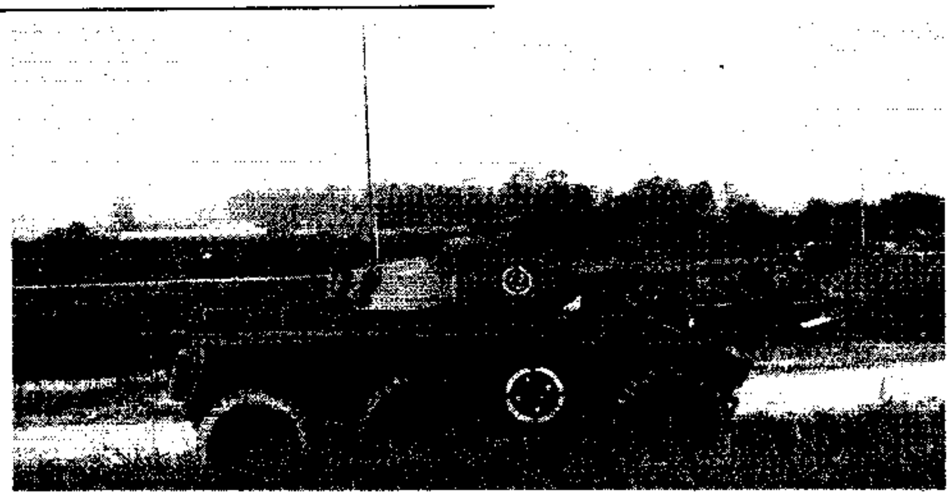
5101.102
EE-9 CASCAVAL ARMOURED CAR

DESCRIPTION:

Design of the EE-9 started in July 1970 and the first prototype was completed in November 1970: it uses many components of the EE-11 Urutu armoured personnel carrier (5102.102). It was developed by Engesa with the assistance of the University of Sao Paulo and the Brazilian Army. The prototype was armed with a 37 mm gun but production vehicles will be fitted with 90 mm gun as fitted to the French AML 90.

CHARACTERISTICS:

Crew: 3 (Commander, gunner, driver)
Weight: 10.75 tonnes (laden)



EE-9 Cascavel Armoured Car with 90 mm Gun

Size: Length 5.998 m (gun forward). 5.18 m (hull only). Height 2.33 m. Width 2.44 m
Road Speed / Range: 100 km/hr/800 km
Main Armament: French 90 mm gun (Model D.921)
Max anti-tank range of main armament: 1500 m
Ammunition types: HE (m/v 650 m/s) and Hollow Charge (m/v 760 m/s) Total of 20 rounds carried
Secondary armament: Coaxial 7.62 mm MG
Engine: Mercedes Benz (Brazil) 6 cylinder, in-line diesel developing 172 hp at 2,800 rpm.
Transmission: Clark gearbox with five forward and one reverse gears. Single plate clutch
Agility: Max step: .6 m. Max gradient 60%
Ground clearance .35 m.
Water crossing ability: Unprepared wading to 1.0 m

STATUS:
Production of a small batch is under way for the Brazilian Army

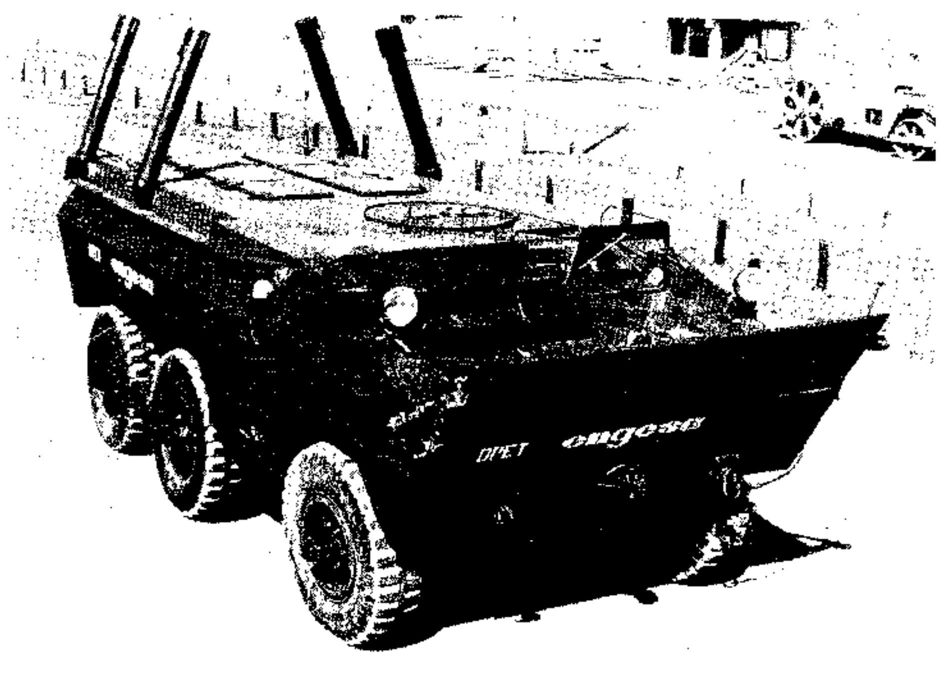
MANUFACTURER:
Engesa, Sao Paulo, Brazil

5102.102
EE-11 URUTU ARMOURED PERSONNEL CARRIER

DESCRIPTION:
The EE-11 Urutu has been designed by Engesa: the first prototype was completed in July 1970 and in 1972 Engesa received a production order for the vehicle.

The hull of the EE-11 is of all-welded construction. The driver is on the left with the engine to his right. There are doors in each side of the hull, a single door is provided at the rear and there are hatches in the roof. Firing ports are provided on either side of the hull and at the rear. A wide range of armament installations can be provided including a single 7.62 mm or 12.7 mm MG on a ring mount, turret mounted 7.62 mm or 12.7 mm MGs, turret mounted 20 mm cannon, or a turret mounted 76 mm or 90 mm gun. Various types of engine can be installed, according to customer requirements. The basic model is fully amphibious for crossing inland waters and optional equipment is available to enable it to operate in heavy seas.

CHARACTERISTICS:
Crew: 15 (driver plus 14 men)
Weight: 10.50 tonnes (laden)
Size: Length 5.76 m. Height 2.0 m (without armament). Width 2.44 m
Road Speed / Range: 95 km/h/700 km
Main Armament: See above
Engine: Mercedes Benz (Brazil) 6 cylinder, in-line diesel developing 172 hp at 2800 rpm
Transmission: Gearbox has five forward and one reverse gear. Two speed transfer case
Agility: Max step: .6 m. Max gradient 60%.



EE-11 Urutu Armoured Personnel Carrier

Ground clearance .35 m
Water crossing ability: The basic model is amphibious being propelled in the water by its wheels. If required it can be fitted with two propellers and two rudders, this model can operate in heavy seas.

STATUS:
The basic model is in production for the Brazilian Army and the Brazilian Marines have ordered some fitted with propellers.

MANUFACTURER:
Engesa, Sao Paulo, Brazil

CHINA (PEOPLE'S REPUBLIC)

5042.102
T59 MAIN BATTLE TANK

DESCRIPTION
Very few details of the Chinese tank manufacturing programme are available. It is known that there are two large tank factories in the neighbourhood of Mukden, and it is believed that the bulk of the current production is based on the T59 tank, which is a modified version of the T54 Soviet tank (**5049.102**), 3,000 of which were supplied to China in the 1950s and early 1960s. Production of T59 is believed to have started in 1963.

The major differences from the T54 appear to be the lack of a gun stabiliser and of infra-red equipment, and the omission of power traverse. Both the gunner and loader have hand traverse mechanisms, but this must mean a very poor rate of engagement and difficulty of engagement on anything but a flat fire position. This information is not recent, however, and it may well be that tanks in current production are superior to the early models. Some of the early production tanks were supplied to Pakistan in 1966 and much of the available information has come from that source.

Chinese built T59 Tank on a parade in Pakistan

5103.102
T-60 LIGHT TANK

DESCRIPTION:
The T-60 Light Tank is a development of the Soviet PT-76 Light Tank (**5038.102**), some of which were supplied to China by the Soviet Union in the late 1950s.

It has six road wheels with the driving sprocket at the rear and the idler at the front. The turret, which is similar in shape to that fitted to the T-59 (**5042.102**), is fitted with an 85 mm gun and a co-axial 7.62 mm machine gun. A 7.62 mm anti-aircraft machine gun can be fitted to the turret roof. The T-60 is fully amphibious, being propelled in the water by waterjets.

STATUS:
In service with China, North Vietnam, Pakistan and Tanzania

5104.102
T-62 TANK

DESCRIPTION:
This is said to look like a miniature T-59 and to be armed with an 85 mm gun and a co-axial 7.62 mm machine gun. Loaded weight is about 21 tonnes. Five large road wheels are fitted

STATUS:
In service with Albania, China and Sudan.

5105.102
T-63 TANK

DESCRIPTION:
The only information available on the T-63 is that it is armed with an 85 mm gun and has five small road wheels and four return rollers.

5106.102
TYPE 55 ARMOURED PERSONNEL CARRIER
DESCRIPTION:
This is the Soviet BTR-40 (**5037.102**) built in China. As far as it is known the Chinese model has characteristics similar to those of the Soviet vehicle.

5107.102
TYPE 56 ARMOURED PERSONNEL CARRIER
DESCRIPTION:
This is the Soviet BTR-152 (**5035.102**) built in China. As far as it is known the Chinese model has characteristics similar to those of the Soviet vehicle.

5108.102
M-1967 (or M-1970) ARMOURED PERSONNEL CARRIER
DESCRIPTION:
This is a Chinese designed and built armoured personnel carrier and was first seen in 1967. Its running gear is similar to that fitted to the T-60 (**5103.102**) light tank and may well be based on this vehicle. It has a loaded weight of 10 tonnes and can carry ten men including the driver. Armament consists of a 12.7 mm machine gun.
STATUS:
In service with China and Tanzania.

CZECHOSLOVAKIA

5074.102
OT-64 (SKOT) ARMOURED PERSONNEL CARRIER
DESCRIPTION:
The OT-64 (or SKOT) is based on the Tatra 813 truck. Development started in 1959 and by 1964 the vehicle was in service. The vehicle has a hull of all-welded construction, doors are provided each side of the hull, at the rear are twin doors and there are hatches in the roof. Firing ports are provided in the sides and rear of the vehicle.

The OT-64 is fully amphibious, being propelled in the water by two propellers at the rear. All eight wheels are powered, the front four being used for steering.

CHARACTERISTICS:
Crew: 2 (Commander and driver) plus 18 infantrymen
Weight: 14.8 tonnes (laden)
Size: Length 7.44 m. Width 2.55 m. Height 2.70 m (with turret)
Road Speed / Range: 95 km / hr / 700 km
Armament: See derivatives
Turret Rotation: 360° by hand
Engine: Tatra Model T-928-14 8 cylinder diesel developing 180 hp at 2,000 rpm
Transmission: 8×8 drive. Gearbox has five forward and one reverse gears
Agility: Max step 0.5 m. Max trench 2 m. Max gradient 60%. Ground clearance 0.4 m
Water crossing ability: Fully amphibious, water speed 8.9 km / hr

DERIVATIVES:
Model 1 with or without a single 7.62 mm machine gun.
Model 2 with 7.62 or 12.7 mm machine gun with a curved shield.
Model 3 (Also known as the SKOT-2A). This has a similar turret to that fitted to the BTR-60PB (**5034.102**) and BTR-40P-2 (**5036.102**) vehicles. The turret is armed with 14.5 mm and 7.62 mm machine guns.
Model 4 (Also known as the SKOT-2AP). This has a very high turret with the same armament as the Model 3.
Model 5 with two Sagger anti-tank missiles mounted towards the rear of the vehicle.

OT64B with 12.7 mm MG in turret. This amphibious vehicle can carry up to 20 infantry men

STATUS:
In service with Czechoslovakia, Egypt, Hungary, India, Libya, Morocco, Poland, Sudan, Syria, Uganda

5109.102
OT-62
ARMOURED PERSONNEL CARRIER
DESCRIPTION:
The OT-62 (or TOPAS) is the Czechoslovakian built version of the Soviet BTR-50PK (**5035.102**) armoured personnel carrier. The Czech built version is a better vehicle than the Soviet model and has a higher road speed and a higher radius of action. An NBC system is fitted.

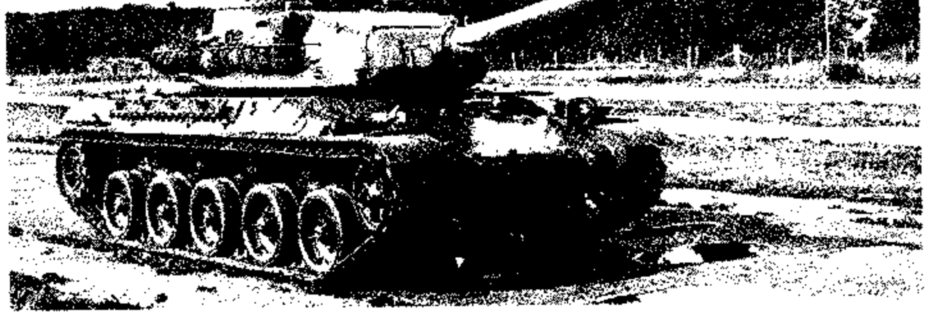
CHARACTERISTICS:
Crew: 2 (Commander and driver) plus 18 infantrymen
Weight: 15 tonnes (laden)
Size: Length 7.08 m. Width 3.14 m. Height 2.35 m (with turret)
Road Speed / Range: 62 km / hr / 450 km
Armament: See derivatives
Engine: PV-6,6 cylinder in line diesel, 132 hp at 1200 rpm
Agility: Max step 1.1 m. Max trench 2.8 m. Max gradient 70% Ground clearance .36 m. Ground pressure 153 kg cm^2
Water crossing ability: Fully amphibious, water speed being 11 km / hr, propelled in the water by waterjets

DERIVATIVES:
Model 1 has two projecting bays, no armament normally fitted.
Model 2 is similar to Model 1 except right bay has a turret fitted with a 7.62 mm MG and a T-21 recoilless rifle.
Model 3 this has a large turret fitted with one 7.62 mm and one 14.5 mm machine guns. Model 3 has a crew of 3 plus 12 infantrymen.
STATUS:
In service with Czechoslovakia, Egypt, Hungary, India, Poland

FRANCE

5018.102
MAIN BATTLE TANK
AMX 30
DESCRIPTION:
The design of AMX 30 stems from the same joint specification agreed by the Defence Ministries of France and West Germany in 1957, as does the Leopard tank. As with Leopard, the priorities in the design were: Firepower, Mobility, and Protection. The trials of the first two prototypes were conducted in 1962, and although these mounted a 105 mm gun, the total weight was kept to 32 tonnes. Later the weight increased in development to 35 tonnes, but even so AMX 30 remains the lightest main battle tank mounting a 105 mm gun.

The semi-automatic gun is electrically fired and can achieve a rate of 8 rounds per minute. Side-mounted on the gunshield this weapon is composed of a 56-calibre barrel, without muzzle brake or smoke evacuator, and a recoil and counter-



AMX30 Tank

recoil mechanism. Recoil length and stress are 380 mm and 25 tons respectively.

Designed primarily as an anti-tank weapon the gun will normally fire either an anti-tank shell with a non-rotating hollow charge (MV – 1,000 m/s) or an anti-personnel high-explosive shell (MV – 700 m/s). It will accept other NATO standard ammunition, however, with the exception of APDS which the French authorities regard as outmoded. The anti-tank shell is effective up to at least 3,000 metres and will perforate up to 360 mm of armour at normal incidence and up to 160 mm at 70 degrees from normal. The HE shell can be used up to 3,500 metres with a flat trajectory and has a maximum range of 11,000 metres with a 20 degree elevation angle. Fifty rounds of 105 mm ammunition can be carried by the tank, of which twenty-two can be in the turret.

For fire control there is an X12 coincidence range-finder for the tank commander and an X8 sighting telescope for the gunner. Normal gunlaying is hydraulic with an emergency manual standby. Gun traverse is unlimited and elevation limits are $-8°$ and $+20°$.

Secondary armament can be either a co-axial 12.7 mm machine-gun paired with the main gun or a co-axial 20 mm gun. In addition there is a 7.62 mm NATO machine gun for close defence.

The mobility of the tank is good, with a high power to weight ratio of 20 bhp/t, the limitation of cross-country performance being set by the suspension system rather than the power available at the sprocket.

The undercarriage is of Vickers type, comprising a rear sprocket wheel, five rubber-tyre double bogie-wheels, five supporting rollers that support only the inner half of the track, a crank-mounted pulley mechanism to stretch the tracks and a centrally-guided track consisting of track shoes on which V-shaped rubber soles are bolted. The suspension is of the torsion-bar type with resilient stops and with hydraulic dampers for the two outer bogie-wheels.

A great deal of care has been given to the optical and sighting arrangements, which are as comprehensive for both daylight and night use as on any main battle tank. The AMX 30 is likely to prove an economical and reliable tank in service.

Ballistic protection is achieved as much by the design of the armour as by its thickness, oblique angles being presented to probable impact wherever possible. The body is made of laminated armour plates and of fully welded cast iron parts. The turret consists of a carapace made of armour steel cast in one piece. For a tank of this type, however, mobility, effective observation and inconspicuous silhouette are as important to protection as its ability to withstand direct attack. In keeping with modern requirements NBC protection has been designed with especial care: absence of unnecessary leaks, an air filtration system and a slight internal overpressure being the main features of this part of the design.

CHARACTERISTICS:

Crew: 4 (Commander, loader, gunner, driver)

Weight: 36 tonnes (laden)

Size: Length, with gun reversed 9.48 m. Length of chassis 6.60 m. Width 3.10 m. Height to top of turret 2.29 m. Height overall 2.86 m

Road Speed/Range: 65 kmh/5-600 km

Main Armament: 105 mm QF gun

Method of ranging: Optical coincidence range-finder

Rounds carried: 50 rounds. Mixed HEAT and HE

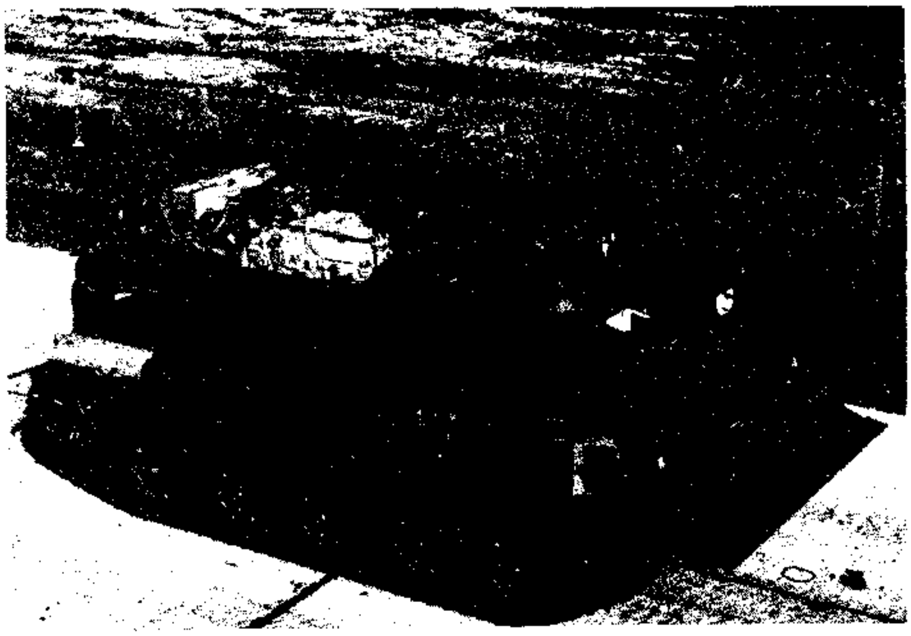
Max Anti-tank range of main armament: 3,000 metres

Secondary Armament: Coaxial 12.7 mm MG (likely to be replaced by 20 mm cannon in some production tanks). One 7.62 mm MG on Commander's cupola

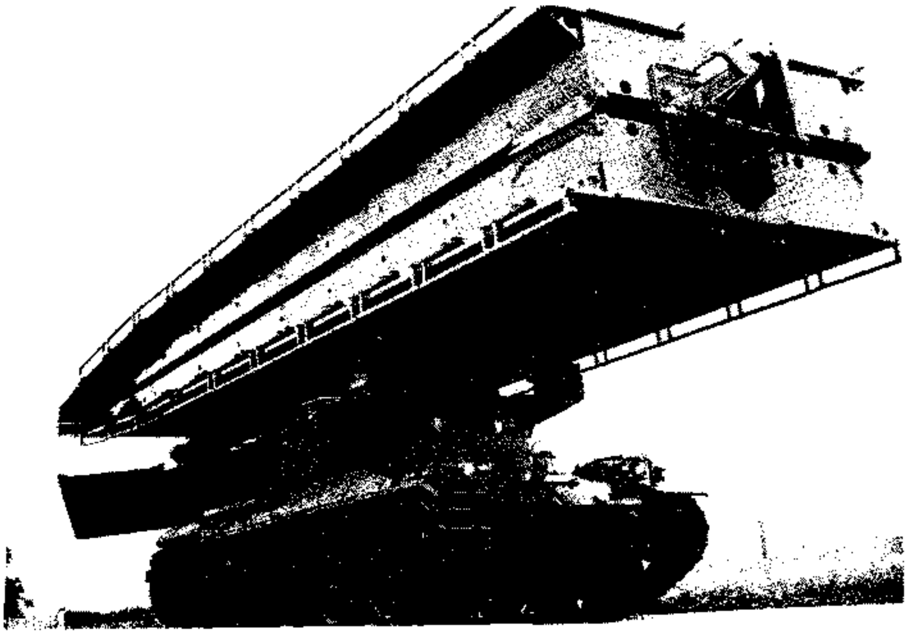
Turret Rotation: 360° in 12 secs

Engine: Hispano Suiza HS 110 flat-12 cylinder multifuel supercharged diesel. 720 bhp at 2,600 rpm

Transmission: Mechanically operated gearbox giving 5 forward, one reverse gear. Centrifugal automatic clutch, electrically controlled by the gear lever.



AMX-30 Armoured recovery vehicle



AMX-30 Bridgelaying tank

Agility: Ground pressure 0.77 kg/cm². Max step 0.9 m. Max trench 2.9 m. Max gradient 60% (1 in 1.7). Ground clearance 0.45 m. Power-to-weight ratio 22 bhp/tonne

Water crossing ability: Unprepared wading depth 2.2 m. (i.e. to top of turret). A snorkel adaptation enables wading to 4 m to be conducted

NBC Protection: The air supply for the crew can be passed through a three-stage filter unit in the turret when the tank is closed down

Night Vision Equipment: Searchlight for white light or IR mounted above the gun. IR sights for commander and gunner can be fitted.

AMX-30 DERIVATIVES:

Bridgelayer

The bridgelayer version has a hinged span 22 m long which can be used to bridge a 20 m gap: it takes 10 minutes to lay and remove the bridge. The bridge is composed of one span in two hinged elements with removable widening panels and wheel guides. Without widening panels the width of the bridge is 3.1 m, but this may be increased to 3.93 m by the use of widening panels.

The bridge can be laid from slopes up or down to 30° and with a tilt of 15°. The span can be laid or removed from either end. It has a crew of three men (commander, operator and driver). Main dimensions of the bridgelayer in road trim are – length 11.5 m, width 3.8 m, height 4 m. Weight with the bridge is 40 tonnes and without the bridge 32 tonnes.

Recovery Vehicle

This has a crew of four men (commander, driver/radio operator and two mechanics). Equipment fitted includes an hydraulically operated spade at the front of the vehicle; the main winch has a capacity of 35 tonnes and the auxiliary winch a capacity of 4 tonnes, cable lengths being 90 m and 120 m respectively. The hydraulically operated crane can lift between 4 and 15 tonnes and can be rotated through 240°. Loaded weight with a spare power unit is 40 tonnes and it has a maximum road speed of 60 km/hr. Overall dimensions are – length 7.18 m, width 3.14 m and height 2.65 m.

AMX-30-S 401 A Anti-Aircraft vehicle with twin 30mm cannon – see entry 2138.131 and 5539.103

AMX-30 Javelot Anti-Aircraft System – see entry 2110.131

AMX-30 155mm GCT – see entry 5574.103

AMX-30 Roland Anti-Aircraft System – see entry 2218.131

AMX-30 with Pluton missile – see entry 2130.111

AMX-30S

This is now in production. It differs from the basic AMX-30 in that it has been designed to operate in very high temperatures. The modifications to the basic vehicle include: slightly lowered gear box ratios, the engine develops 620 hp at 2400 rpm, sand shields have been fitted. The road speed is now 60 km/hr. A light intensifying passive driving periscope can be fitted and a laser rangefinder is under development.

AMX-30 STATUS:

In production. On order for, or in service with, the following countries – Chile, France, Greece, Iraq, Libya, Peru, Saudi-Arabia, Spain, Venezuela.

MANUFACTURERS:

Groupement Industriel des Armements Terrestres, 10, place Georges Clémeneeau, 92211 Saint Cloud, France.

5020.102 LIGHT TANK AMX 13

DESCRIPTION:

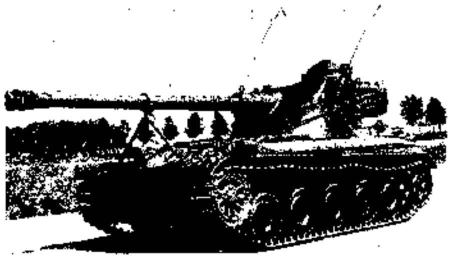
One of the most successful tanks produced since the Second World War, the AMX 13, has a history extending back to a requirement issued in 1946. It has been in production for some twenty years – during which time it has undergone numerous modifications to meet changing requirements and take advantage of technological improvements – and is still manufactured in very large numbers.

Original main armament was a 75 mm gun; but later versions mounted a 90 mm gun, in which form the tank is currently in service with the French Army, and a 105 mm gun, which is the version currently in production. The 105 mm gun fires the same anti-tank shell as is fired by the AMX-30 tank gun (**5542.103**) but with a muzzle velocity of 800 m/s: this shell will perforate up to 360 mm of armour at normal incidence. The gun will also fire a high-explosive anti-personnel shell with a muzzle velocity of 700 m/s. The gun is fired electrically.

By far the most notable feature of the AMX-13 tank is the use of an oscillating turret (see **2149.103**) which makes it possible to incorporate an automatic loading device for the main gun while still achieving a low profile for the turret. This automatic loading system permits a high rate of fire while requiring only two men in the turret.

In order to keep weight down the AMX-13 is not heavily armoured and relies extensively on its mobility and on its low silhouette for protection on the battlefield. It is indeed the lightest tank to mount a 105 mm gun.

From the basic tank a family of 23 armoured vehicles has been developed over the years; and, apart from those supplied to the French Army, some 4,000 of various members of the complete family have been exported to Algeria, Argentina (has also assembled AMX-13s, the first one being completed in 1969), Austria, Cambodia, Chile, Dominican Republic, Ecuador, Egypt, France, India, Indonesia, Israel (few, if any, remain in service), Ivory Coast, Jordan, Kenya, Lebanon, Morocco, Netherlands, Nepal, Peru, Saudi Arabia, Singapore, South Vietnam, Switzerland, Tunisia, Venezuela.



AMX13 with 105 mm gun

AMX-13 with 90 mm gun (ECP Armées)

CHARACTERISTICS:

Crew: 3 (Commander, gunner, driver)

Weight: 15 t in combat order

Size: Length 4.88 m (chassis only); 6.36 m (including 90 mm gun); 6.50 m (including 105 mm gun). Width 2.50 m. Height 2.30 m

Road Speed: 64 km/h

Main Armament: 105 mm gun (MV 800 m/s) or 90 mm gun (MV 950 m/s) or 75 mm gun (MV 1,000 m/s)

Secondary Armament: Coaxial 7.5 mm or 7.62 mm MG.

Method of Ranging: Optical rangefinder linked to sight and laser rangefinder.

Main Armament Rounds Carried: 32 rounds of 105 mm or 34 of 90 mm. 12 rounds in the automatic loader magazines

Night Equipment: IR searchlight and IR sights

Turret Rotation: 360°; power-assisted traverse mechanism

Engine: SOFAM Type 8GXb, 8 flat in-line cylinders – petrol spark ignition 250 bhp

Agility: Ground pressure 0.76 kg/cm². Max step 0.65 m. Max trench 1.6 m. Max gradient 60% (31°). Ground clearance 0.37 m. Power-to-weight ratio 16 bhp/ton.

DERIVATIVES:

As noted above, the AMX-13 family of derivatives numbers 23. Some of the more important are:

- 155 mm SP Howitzer
- 105 mm SP Howitzer
- Anti-aircraft tank (various calibres)
- Mortar vehicle (81 or 120 mm)
- Armoured personnel carrier
- Bridge-layer
- Dozer
- Recovery vehicle
- Ammunition carrier
- Ambulance

STATUS:

With 75 mm gun: still in service outside France.

With 90 mm gun: in service as standard equipment of French mechanised infantry brigades and elsewhere.

With 105 mm gun: in service in several countries outside France.

MANUFACTURER:

Creusot-Loire (Groupes Marine Schneider), 15, rue Pasquier, 75383-Paris, France.

5009.102 AMX 10P ARMOURED PERSONNEL CARRIER

DESCRIPTION:

This amphibious armoured personnel carrier is the first tracked APC developed in France which has not been adapted from a tank design. Its high, straight sides make it amphibious, and water-jet propulsion is used to give it an impressive water-crossing performance. It is powerfully armed with a 20 mm cannon which is operated from below armour, so that no member of the crew need be exposed. Prototypes of this vehicle have been under trial since 1969 and production for the French armed forces began in 1973.

CHARACTERISTICS:

Crew: 11 (Driver, gunner plus section of 9 infantrymen)

Weight: 13.8t in combat order, 11.3 t in travel order

Size: Length 5.85 m. Width 2.78 m. Height to top of turret 2.54 m (hull only 1.87 m)

Road Speed: 65 km/h

Cross-country Speed: 30-40 km/h

Water Speed: 6.5 km/h (by tracks)

Road Range: 600 km

Combat Range (NATO war mission): 24 hours

Engine: Hispano Suiza watercooled, multi-fuel 280 bhp at 3,000 rev/min

AMX 10 Amphibious Armoured Personnel Carrier

AMX 10P on rough ground

Armament of the AMX10P, 20 mm cannon and 7.62 coaxial MG operated from inside the vehicle

Interior of the AMX10PC Command Post Vehicle

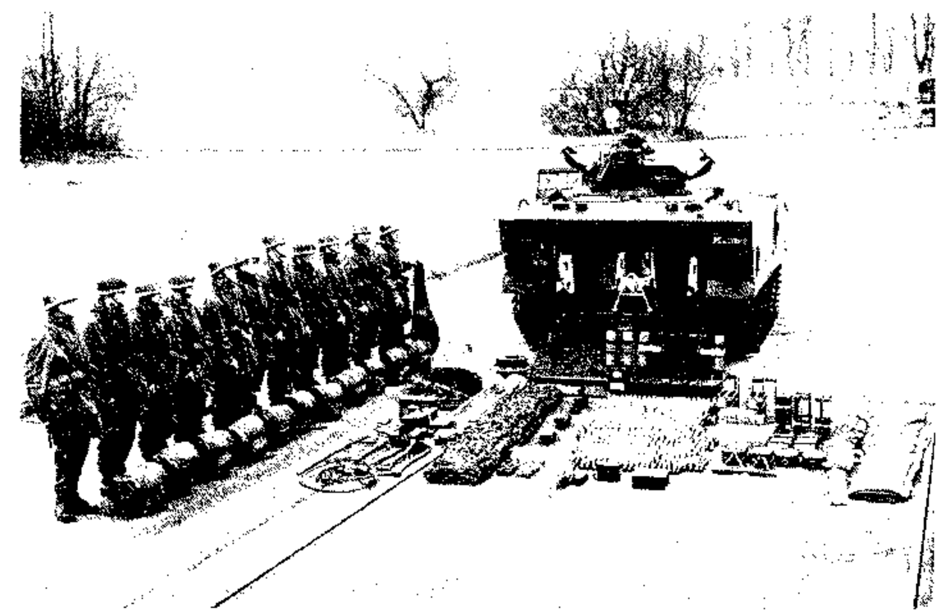
Transmission: 4 forward, 1 reverse pre-selected gears with hydraulic torque converter
Agility: Ground pressure 0.53 kg/cm². Max step 0.7 m. Max trench 1.6 m. Max gradient 60%. Power to weight ratio 20 bhp/ton
Armament: 20 mm cannon. 350 ready rounds + 450. 7.62 mm MG 900 ready rounds + 1,100. Both operated from inside the turret
Sights: Gunner, × 2 and × 6. Commander × 1 and × 6. Optional night observation and firing equipment

VARIANTS:
The French authorities are taking the AMX10P vehicle as the starting point for a substantial AMX10 family of AFVs

The first of these are the AMX-10TM, which tows the Hotchkiss-Brandt 120 mm mortar and has a crew of six, and the AMX-10PC command vehicle. Under development is the AMX-10D recovery vehicle, AMX-10M anti-tank vehicle with ACRA (**2071.111**) or HOT (**2212.111**) missiles and the AMX-10C with turret- or hull-mounted 105 mm gun.

Also under development is a wheeled family of vehicles, the first of which, the AMX-10R, was shown in 1971; in 1973 the AMX-10RC (**5110.102**) was shown.

MANUFACTURER
GIAT (Groupement Industriel des Armements Terrestres) 10, place Georges Clémenceau, 92211 Saint-Cloud, France.



This picture of the AMX10P with its large rear door lowered well illustrates the carrying capacity of the vehicle. In addition to the eleven men with their kit, weapons and food and the tools and accessories for the vehicle, the picture shows 800 rounds of 20 mm ammunition and 2,000 7.62 mm rounds

5110.102
AMX-10RC
RECONNAISSANCE VEHICLE

DESCRIPTION:
The AMX-10RC is a member of the AMX-10R family of vehicles at present under development; it was shown for the first time at Satory, in June 1973. All of these vehicles use components of the AMX-10P family (**5009.102**).

The vehicle is fully amphibious, being fitted with waterjets. Its oleo-pneumatic suspension can be adjusted to suit the tactical situation. A full range of passive night driving and night fighting aids are fitted. A comprehensive fire control system is also fitted, including a laser rangefinder.

CHARACTERISTICS:
Crew: 4 (Commander, gunner, loader/radio operator, driver)
Weight: 15 tonnes (laden)
Size: Length 6.243 m (hull). Width 2.78. Height 2.565 m (overall)
Road Speed/Range: 85 km/hr/800 km
Main Armaments: 105 mm gun, elevation −8° to +20°
Method of Ranging: Optical and laser rangefinder
Ammunition: no low-charge finned shell with a m/v of 1000 m/s, maximum m/v being 1500 m/s. Effective range 1650 m
Secondary Armament: co-axial 7.62 mm machine gun
Turret Rotation: 360° hydraulic traverse with manual for use in an emergency
Engine: Hispano-Suiza HS 115-2, V-8 water-cooled, 276 hp at 3000 rpm

AMX-10RC Reconnaissance Vehicle (Christopher F. Foss)

Transmission: 4 forward and 1 reverse pre-selected gears with hydraulic torque converter
Agility: Max step 0.7m. Max trench 1.6 m. Gradient 60%. Ground clearance 0.30 m
Water crossing ability: Fully amphibious
NBC Protection: An NBC system is fitted

STATUS:
Trials with the French Army.

MANUFACTURER:
GIAT (Groupement Industriel des Armements Terrestres) 10 place Georges Clémenceau, 92211 Saint-Cloud, France

5010.102
ARMOURED PERSONNEL CARRIER
AMX-VTP M-56

DESCRIPTION:
Developed during 1955 and 1956 on the basis of a lengthened AMX 13 tank chassis, this APC is still the standard equipment for mechanised infantry in the French Army. A maximum of 12 infantrymen can be carried, ten of them sitting back to back down the middle of the vehicle. Large hatches which open up the sides and top enable the infantry section to use their weapons from the vehicle on occasions. A turret left forward can be equipped with either a 7.62 mm or 12.5 mm MG. The crew can dismount either through two rear doors or through their top hatches. In addition to the French Army, the Dutch, Italian and Belgian armies are equipped with this vehicle. It is likely to be replaced by AMX-10 as this comes into service.

CHARACTERISTICS:
Crew: 13 (Commander, driver plus eleven infantrymen)
Weight: 14 tons (laden)
Size: Height 2.40 m. Length 5.70 m. Width 2.70 m.
Road Speed/Range: 60 kph/370 km
Armament: Turret mounted MG in two versions, either a 7.62 mm or 12.5 mm MG
Turret rotation: 360°
Engine: SOFAM 8, 8 flat in-line cylinders. Petrol spark ignition 270 bhp
Agility: Ground pressure: 0.7 kg/sq cm. Max step 0.65 m. Max trench 1.60 m. Max gradient 60% (31°). Ground clearance 0.48 m. Power to weight ratio 17.8 bhp/ton
Derivatives: The principal derivatives of this basic design are:
Command vehicle, ambulance, dozer vehicle, battery command vehicle, 81 mm and 120 mm

AMX VTP M56 Armoured Carrier armed with 12.7 mm MG mortar vehicles, pioneer vehicle, cargo carrier, artillery support vehicle, missile vehicle with two launchers either side for ENTAC (**2081.111**) anti tank missiles. The Netherlands have fitted a TOW (**2830.111**) system to one of their vehicles for trial purposes.

MANUFACTURER:
Creusot-Loire (Groupes Marine Schneider) 15, rue Pasquier, 75-Paris-08, France.

ARMOURED CAR
AML 245

DESCRIPTION.

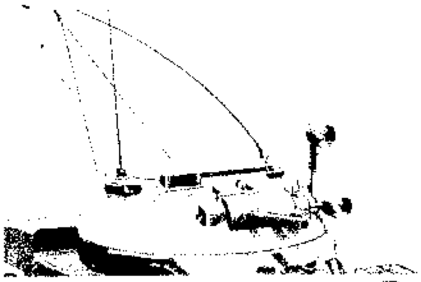
The requirement for a light armoured car for the French Army arose during the Algerian War in the 1950s. A specification was written for a vehicle of similar mobility, but greater firepower, than the Ferret Scout Cars that were then in French Army service. At the same time it was to be lighter and more easily serviced than the 8-wheeled EBR Armoured car. The result was the Auto-mitrailleuse Légère or AML (Panhard Model 245). Prototypes were built in 1960 and production followed with commendable speed, so that the first French Army Units were equipped in 1961. Since then some 4,000 vehicles have been produced in 6 different armament configurations and sales have been made to 27 nations. A large number have also been built under licence in South Africa. The roles of the AML are armed reconnaissance, frontier protection, convoy escort and internal security. Its reliability, silence, and speed make it especially valuable in these roles. Special features include the use of Hutchinson puncture proof tyres, enabling the vehicle to run even when the tyres have been damaged by gunfire or by mine, the long range of 600 kms, and the simplicity and ease of maintenance of the vehicle.

Latest in this series of fighting vehicles is a version mounting the new 60 mm Hotchkiss-Brandt vehicle-mounted mortar (**2151.103**). Another recent addition to the range is the AML HS 30, the "HS 30" referring to the 30 mm Hispano Suiza

AML 245 Turret Types

HE 60-7 Turret

Armament	One 60 mm breech loaded mortar, which can fire direct up to 350 m and indirect to 1,800 m. Also twin 7.62 mm MGs.
Ammunition	53 mortar shells, 3,800 rds MG
Laden Weight of Vehicle	4.8 t

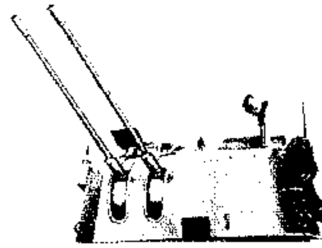


H90 F1-7 Turret

Armament	D921 90 mm gun, firing HE and HEAT ammunition up to 1,500 m range. Also one coaxial 7.62 mm MG.
Ammunition	20 90 mm shells (MV of HE is 650 m/s and of HEAT is 760 m/s). 2,000 rds MG
Laden Weight of Vehicle	5.5 t

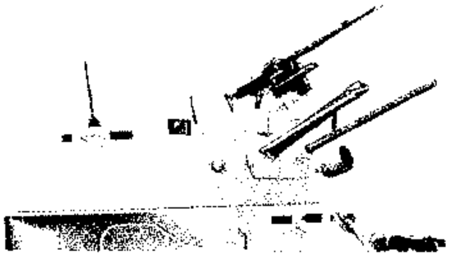
S 530 Turret

Armament	Two AME 621 20 mm anti-aircraft guns. Automatic loading from two magazines of 300 rds.
Traverse speed	80 degrees/s
Elevation speed	40 degrees/s
Firing rate	740 rds/min per barrel
Laden Weight of Vehicle	5.5 t



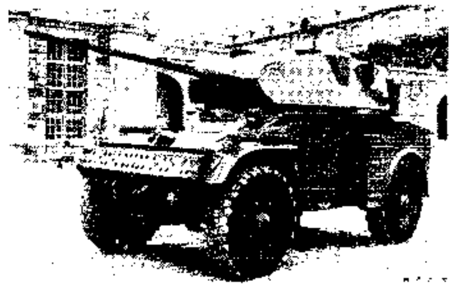
HE 60-20 Turret

Armament	One 60 mm breech-loaded mortar, which can fire direct up to 350 m or indirect up to 1,800 m. Also one automatic 20 mm gun firing HE or AP shells at 750 rds/min with MV of 720 m/sec. A 7.62 mm MG is mounted on the roof.
Ammunition	39 mortar shells, 300 20 mm shells.
Laden Weight of Vehicle	4.9 t



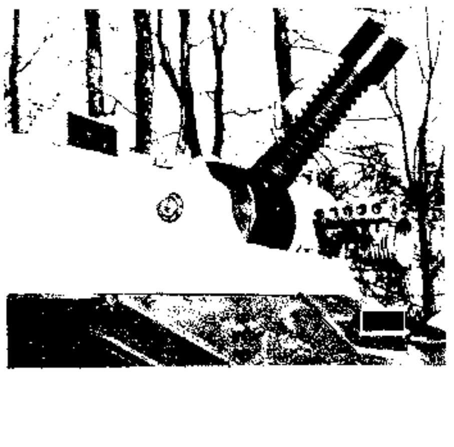
HS 30 Turret

Armament	One HS 30 mm gun (831 SL) for ground and anti-aircraft fire, electrically or manually fired. Also one AA 52 machine gun mounted alongside the 30 mm gun and a second mounted on the turret roof.
Ammunition	200 30 mm rounds (155 on belt) 2,200 rounds MG.
Turret weight	1.9 t in fighting order



HB Vehicle Mortar Turret

Armament	One 60 mm Hotchkiss Brandt Vehicle Mortar type 60 MC A1, breech-loading or muzzle loading (for high angle fire). Twin 7.62 mm Mgs.
Ammunition	53 mortar shells, 3,800 rounds MG (M35-47 or M61 shell and HB "canister" shell)



gun which is the vehicle's main armament. A two-man turret carries this gun and MG and the vehicle is designed to engage both ground and airborne targets – the main gun can be elevated to 75° or depressed to —8° and the practical engagement range is 2,600 metres.

CHARACTERISTICS (common to all turret types):

Crew: 3 (Commander / loader, gunner, driver)

Weight: Varies between 4.8 t and 5.5 t depending on turret type

Size: Height 2.1 m. Length (hull 3.79 m). Width 2.0 m.

Road Speed / Range: 100 km / h / 600 km

Method of Ranging: Commander's estimation

Turret Rotation: 360°, manually operated traverse on all except S530 turrets, 15 secs per revolution

Engine: Panhard 4HD 4 cylinder horizontally opposed air cooled petrol engine. 1,997 cc. 90 bhp at 4,700 rpm. Compression ratio 7 : 1

Transmission: Manually operated gearbox with six forward and one reverse gear. Electrically operated centrifugal clutch eliminating need for a clutch pedal

Agility: Ground pressure about 0.98 kg/cm varying slightly with different turrets. Maximum step 0.3 m. Maximum trench 0.78 m with one set of ditch plates, can be increased to 3.1 m using ditch plates from four cars. Maximum gradient 60% (1 in 1.6). Ground clearance 0.33 m. Power to weight ratio varies from 16 to 19 bhp / t depending on turret type.

Water crossing: By fording, without preparation to depth of 1.1 m

Variant: The VTT-AML APC, separately described, uses 95% similar components.

Amphibious AML

A major feature of Panhard's recent work on the AML has been the enlargement of its capabilities by making it amphibious. This has been done by boxing the existing armoured hull of the vehicle with thin sheet-metal coffers filled with expanded polyurethane. This material has the advantages of being self-extinguishing when ignited, of being non-absorbent and therefore buoyant and of providing a detonating point for a hollow charge projectile before it reaches the armour plate. The added materials increase the all-up weight by only about 10% and the vehicle is then amphibious.

STATUS:

In production. The AML is in service with the following countries – Algeria, Burundi, Cambodia, Congo, Ecuador, Eire, Ethiopia, France, Iraq, Israel, Ivory Coast, Kenya, Libya, Mauritania, Morocco, Malaysia, Nigeria, Portugal, Rhodesia (from South Africa), Rwanda, Saudi Arabia, Senegal, South Africa, Spain and Tunisia.

MANUFACTURER:

Société de Constructions Méchaniques Panhard et Levassor, 18 Avenue d'Ivry, Paris 13e, France.

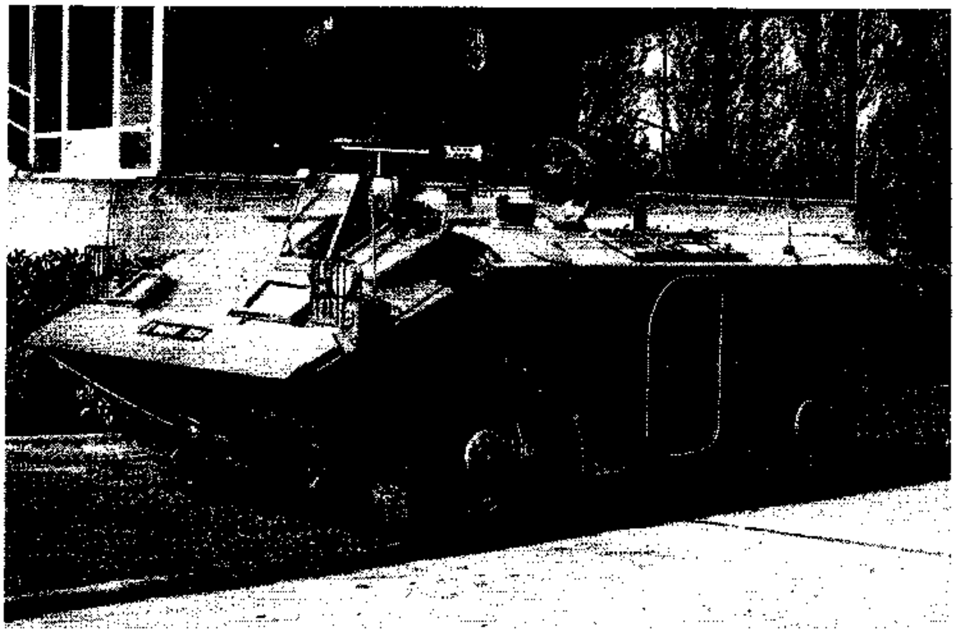
2158.102
NEW PANHARD WHEELED VEHICLES

DESCRIPTION:

Panhard has built prototypes of a new range of wheeled armoured vehicles. These are known as the M4 (4 × 4), M6 (6 × 6) and M8 (8 x 8). They all have hulls of all welded construction and are fully amphibious being propelled in the water by two propellers at the rear of the vehicle, water speed being 6/7 km/hr. They have doors in the sides and rear of each vehicle and firing ports are provided. Hydropneumatic suspension is fitted, allowing the height of the vehicle to be adjusted. They all use a number of similar components such as suspension units and gearboxes, thus keeping logistics and costs to a minimum. The conventional clutch has been replaced by an hydraulic converter that ensures a smooth transmission: the gear box has two ranges. An NBC system is fitted.



Panhard M4 vehicle

CHARACTERISTICS

	M-4	M6	M-8
Crew:	10	10	12
Weight (laden):	10.9 t	11.8 t	13 t
Length:	5.305 m	5.855 m	6.70 m
Width:	2.50 m	2.50 m	2.50 m
Height (low):	2.53 m	2.53 m	2.53 m
Height (road):	2.67 m	2.67 m	2.67 m
Height (cross country):	2.79 m	2.79 m	2.79 m
Road speed:	90 km/hr	90 km/hr	90 km/hr
Road range:	1000 km	1000 km	1000 km
Max step:	.60 m	.91 m	.80 m
Max trench:	1.1 m	1.9 m	2.2 m
Max gradient:	60%	60%	60%
Fording:	Amphibious	Amphibious	Amphibious

DERIVATIVES:

M-4 – This can be fitted with a wide selection of turrets up to and including a 90 mm gun. It can be powered by a Caterpillar 1150 developing 200 hp/3000 rpm or a Berliet V800 developing 165 hp/3000 rpm or a Baudouin DF 6S developing 185 hp/3000 rpm. A Voith 502-3 automatic gearbox is fitted.

M-6 – This can be fitted with a wide selection of turrets up to and including a 90 mm gun. It is powered by a Caterpillar 1150 developing 200 hp/3000 rpm or a Caterpillar 1160 developing 225 hp/2800 rpm or a Baudouin DF 6S developing 185 hp/3000 rpm. It has a Voith 502-2 automatic gearbox.

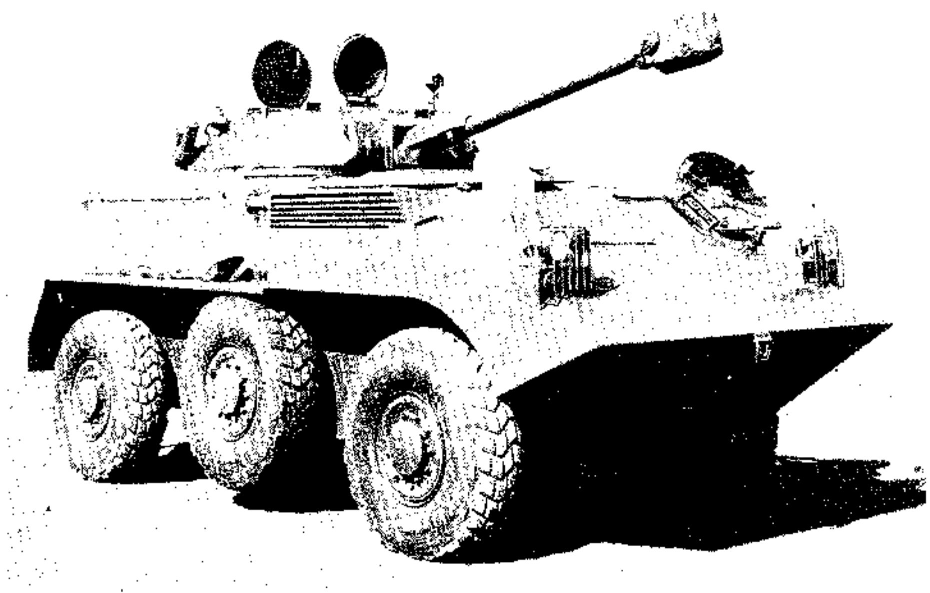
M-8 – This can be fitted with a wide selection of turrets up to and including a 105 mm gun (ie the same as that fitted to the AMX-10RC 6 × 6 vehicle **5110.102**). It is powered by a Caterpillar 1160 engine developing 225 hp at 2800 rpm and a Voith 502-3 automatic gearbox is fitted.

STATUS:

The Panhard M-4 and M-6 are being tested by the French Army and are in competition with the Saviem VAB (**5111.102**).

MANUFACTURER:

Société de Constructions Mécaniques, Panhard et Levassor, 18, Avenue d'Ivry, Paris 13e, France.



Panhard M6 vehicle

Panhard M8 vehicle

5022.102
M3/VTT
ARMOURED PERSONNEL CARRIER

DESCRIPTION

This comparatively recent vehicle has been developed from the AML 245 Armoured Car, and has 95% compatibility in mechanical components with the earlier vehicle. It is designed especially for use in counter-insurgency and internal security situations, where large numbers of armed men have to be conveyed swiftly, silently and safely to a trouble spot. It is likely to be especially valuable in this respect in city riots and other similar situations and the vehicle has indeed already been adopted officially by the French police. In addition to the crew of two, it will carry ten fully armed infantrymen. To permit exit through the back of the vehicle, the engine position has been

The M3 / VTT armoured personnel carrier

moved forward from its position at the rear of the AML 245 Armoured Car to just behind the driver on this vehicle. The box-like structure of the body, mostly fabricated from 10 mm armour plate, allows the vehicle to be fully amphibious.

A variety of different armaments can be carried, either with a fully rotating cupola or with a roof mounted weapon. Several variants to the basic design for special functions are now in development. The vehicle is now in full production and has already been sold to several countries.

CHARACTERISTICS:

Crew: 12 (Commander, driver plus 10 armed men) as APC

Weight: 5.8 t

Size: Height over CAFL turret 2.24 m. Length 4.45 m. Width 2.4 m

Road Speed / Range: 100 km / h / 600 km

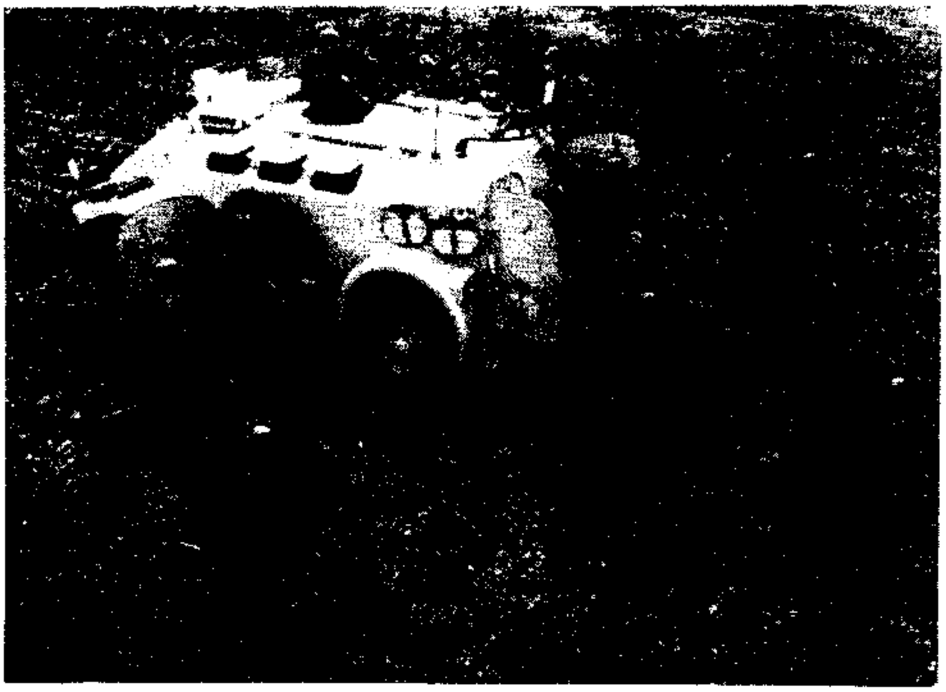
Armament: Various

Access: Two side doors and two rear doors

Engine and Transmission: As for AML 245

Agility: As for AML 245 except that power to weight ratio is 16.5 bhp / t

Water crossing ability: Inherently amphibious; propulsion by wheel spin



The personnel-carrying capacity of the M3-VTT is well illustrated here

VARIANTS:

The basic M3 can also be used as an ammunition / load carrier, mortar carrier, radio / command vehicle, workshop vehicle or an ambulance. Shown at Satory in 1973 was the M3 VDA Anti-Aircraft vehicle armed with twin 20 mm cannon (**2164.131**).

STATUS:

In production. In service with Abu-Dhabi, Congo, Eire, France, Iraq, Kenya, Lebanon, Malaysia, Saudi-Arabia.

MANUFACTURER:

Société de Constructions Mécaniques, Panhard et Levassor, 18, Avenue d'Ivry, Paris 13e, France.

5059.102
BERLIET VXB ARMOURED PERSONNEL CARRIER

DESCRIPTION:

The BL12 prototype amphibious armoured personnel carrier developed by the Berliet company between 1965 and 1968 was evaluated by the French Army in 1969. As a result of this trial, a modified version of the same vehicle, known as VXB, has now been designed. The VXB incorporates the considerable experience that the Berliet company have gained in the development of trucks and heavy wheeled vehicles for military and civil use. It is a robust, reliable and easily maintained vehicle with good cross-country performance.

CHARACTERISTICS:

Crew: 12 (Commander, driver and 10 infantrymen)

Weight: 15.5 t

Size: Height (to top of turret) 2.0 m. Length 5.92 m. Width 2.5 m

Road Speed / Range: 85 km / h / 750 km

Armament: See under Variants

Engine: Berliet V800 Diesel. 8-cylinder V type, 6.92 litres. 160 bhp at 3,000 rpm

Transmission: Berliet synchromeshed and air-assisted gearbox giving six forward and one reverse ratios

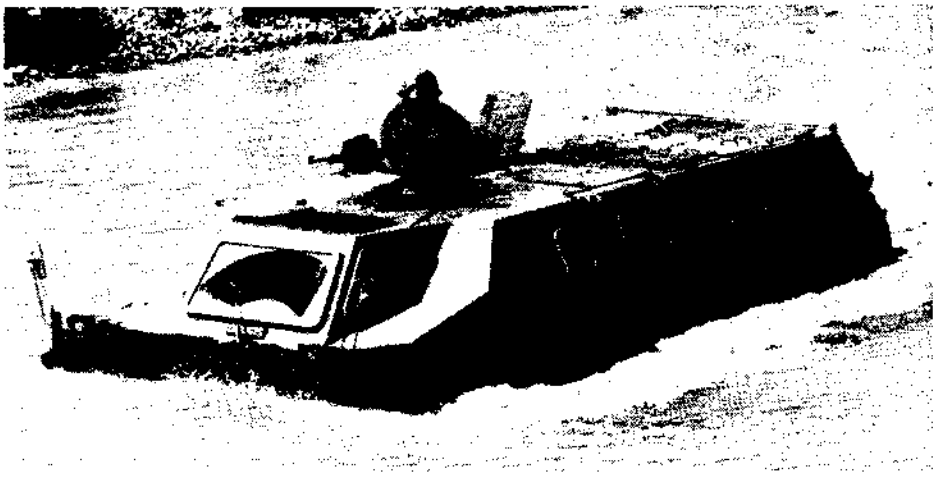
Agility: Maximum gradient 60%. Ground clearance 0.48 m. Power to weight ratio 14.2 bhp / t

Water crossing ability: Full amphibian, propulsion by wheel spin at 4 km / h

Exit for crew: The engine is at the rear of the vehicle. Exit is by two large doors at the centre of each side

Self-recovery: A 4.5 t winch is fitted at the front

The Berliet VXB Amphibious Armoured Personnel Carrier



Berliet VXB swimming

as a standard feature, particularly designed to assist in negotiating steep river banks.
VARIANTS:
A wide range of possible uses of the VXB has been proposed and prototype models embodying many of these proposals have been constructed. The vehicle can be used as a personnel carrier, as a carrier of a smaller number of troops with a substantial volume of stores, as an ambulance and as a cargo carrier.
Allied with these internal arrangements is a range of possible armament configurations extending from the provision of one or more MGs in single mountings on the hull to fully rotating one-man turrets armed with MGs or 20 mm cannon.
STATUS:
In service with the French Gendarmerie.
MANUFACTURER:
Automobiles M. Berliet, Département des Affaires Militaires, 160 Boulevard de Verdun, 92-Courbevoie, France.

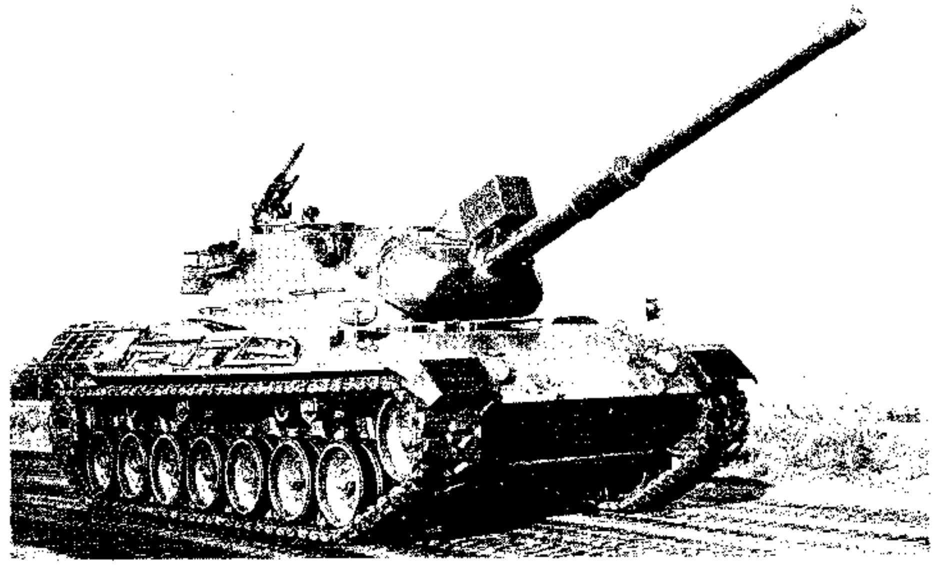
5111.102
SAVIEM VAB
FRONT ARMOURED VEHICLE
DESCRIPTION:
The Saviem VAB (Vehicule de l'Avant Blindé) has been developed under a programme laid down by the French Army and is in competition with the Panhard M-4 and M-6 vehicles (**2158.102**).
There are two models in the range, a 4 × 4 and a 6 × 6, both of which have the same over-all dimensions and use the same components. They have hulls of all-welded construction and are fitted with an NBC system. The vehicles are fully amphibious and can be fitted with a winch. A wide range of roles is envisaged including a troop carrier (12 men), missile vehicle, mortar carrier, cargo vehicle (up to 2 t of cargo), command post, ambulance, radio vehicle and recovery vehicle. Various types of armament can be fitted including 20 mm cannon.
CHARACTERISTICS:
Crew: 2 (commander and driver)
Size: Length 5.855 m, Width 2.48 m, Height 2.06 m
Road Speed / Range: 90 km / hr / 1000 km
Engine: 6 cylinder diesel, 245 hp
Transmission: Either mechanical with 6 gears or hydraulic with 5 gears and a converter
Agility: Max gradient 70%. Ground clearance .40 m
Water crossing ability: Fully amphibious
STATUS:
Under test by the French Army
MANUFACTURER:
Saviem, 8 quai Léon Blum, 92152 Suresnes, France.

GERMANY (FEDERAL REPUBLIC)

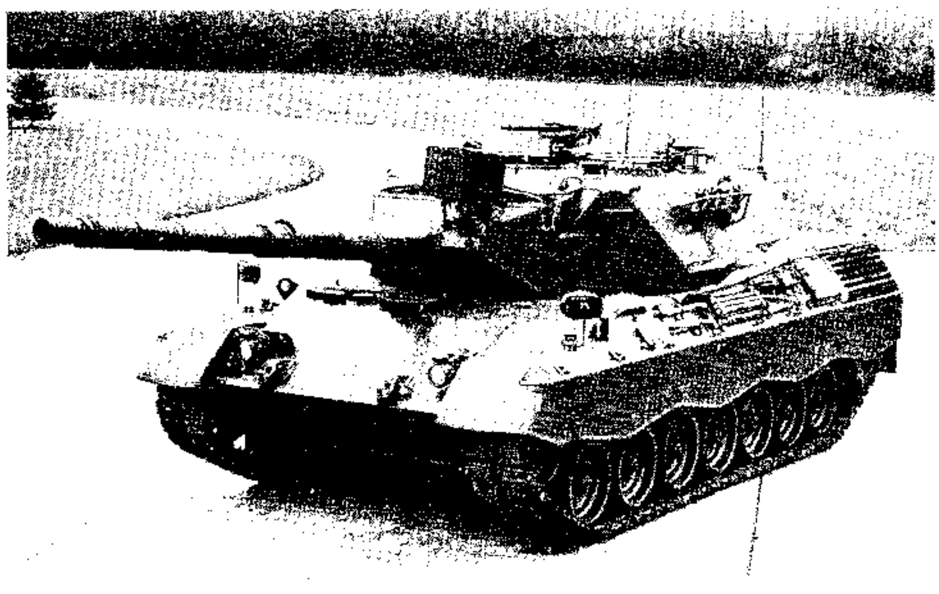
5015.102
MAIN BATTLE TANK
LEOPARD
DESCRIPTION:
Leopard is the first main battle tank to be manufactured in Germany since 1945, and it has been an extraordinarily successful achievement. The specification drawn up jointly by the Defence Ministries of France and Germany in 1957 listed the priorities for the design in order as: Firepower, Mobility, Protection. The intention of this joint agreement was to devise a NATO standard tank in the 30 t class. In the event a joint design could not be achieved, and the French initiated the design which eventually emerged as AMX 30, whilst the Germans designed Leopard.
The firm of Krauss-Maffei were chosen as overall contractors for series production of Leopard Tanks and Gepard AA Tanks (**2370.131**). The ARV, CEV and Bridgelayer versions were prepared by MaK Maschinenbau GmbH of Kiel. The testing of a 155 mm GCT on a Leopard chassis has started.
The first Leopard left the production line on 9th September, 1965, the first ARV, exactly a year later, on 9th September, 1966, and the first Bridgelayer (know known as Biber) in November 1973. Up to November, 1973, 3141 Leopards had been built: Germany (2187), Belgium (334), Netherlands (342), Italy (200) and Norway (78). 600 tanks are being built under licence by Oto-Melara in Italy (**2005.102**). there is also an additional order for 250 tanks for the German Army.
670 Leopard variants have been built by MaK of Kiel distributed as follows:

	ARV	CEV	BRIDGELAYER
Germany	444	36	6
Belgium	36	6	
Netherlands	41	14	–
Italy	69	12	–
Norway	6	–	–

The production of 105 Bridgelayers for Germany and 14 for the Netherlands is anticipated.
In mid-1976 the series production by Krauss-Maffei of 420 Gepards (Anti-Aircraft Vehicle) for the German Army and 95 for the Netherlands will begin. Belgium is interested in purchasing 55 and Italy 130.
The features that have contributed to the success of Leopard, can be summarised as:
1. Exceptional mobility, especially on hard going, achieved by a power to weight ratio of 21 bhp/t.
2. A powerful, accurate and quick firing gun (the 105 mm L/A3) which accepts the standard NATO ammunition stockpiled in huge quantities.
3. The reliability and long life of components due to good design and intensive environmental testing.
4. The ease of maintenance, and ease of crew training due to the absence of electronic luxuries.

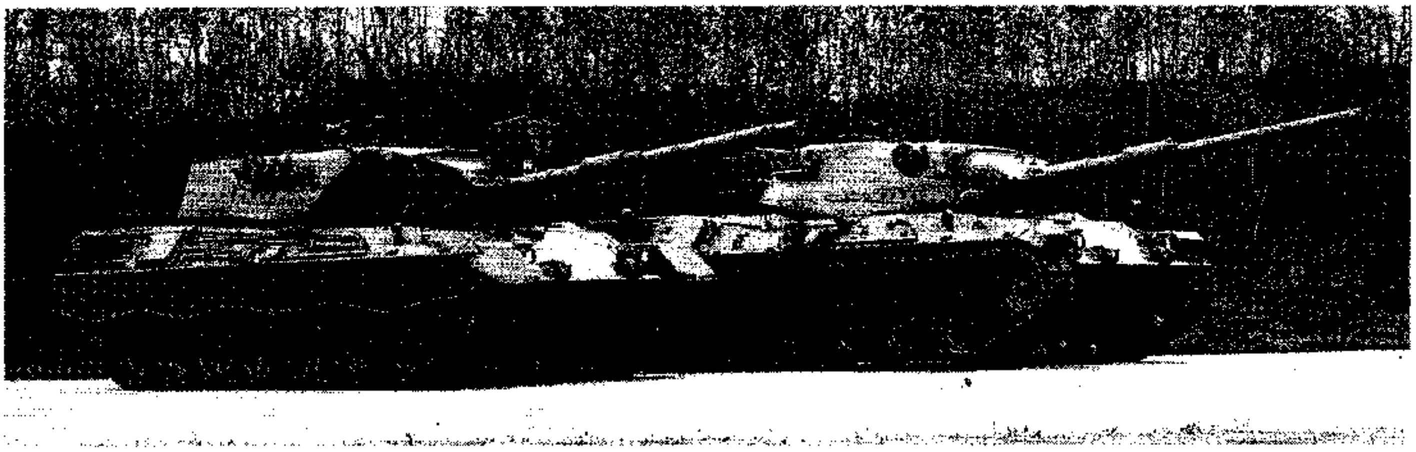


The Leopard Tank as originally delivered

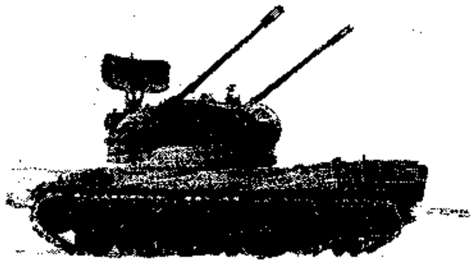


Leopard A3 MBT with new turret

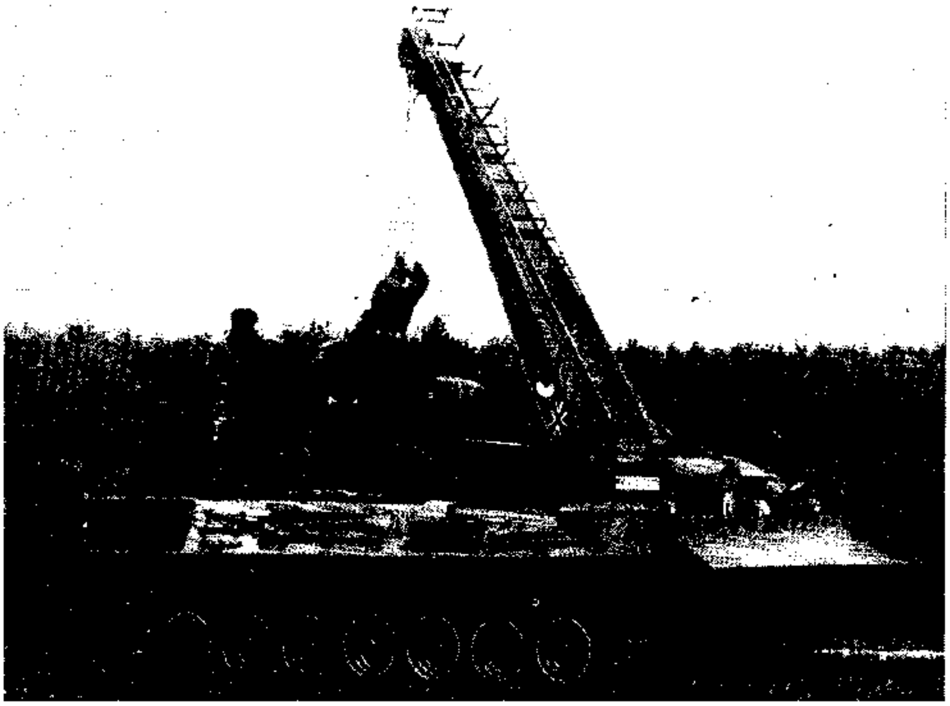
CHARACTERISTICS:
Crew: 4 (Commander, loader, gunner, driver)
Weight: 42.2 tonnes (laden)
Size: Height 2.62 m, Length (hull) 6.94 m, Width 3.25 m



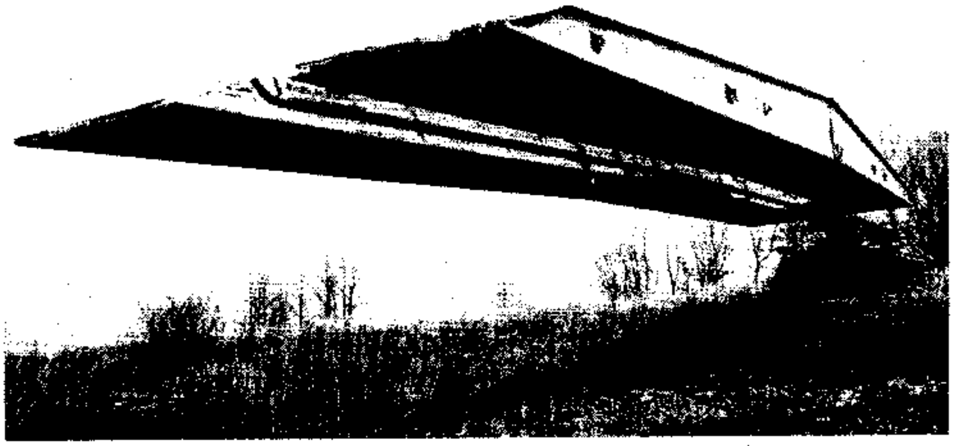
Leopard A3 (left) *and A2* (right)



Flakpanzer Gepard – German version of the AA vehicle



Leopard Armoured Recovery Vehicle



Leopard Bridgelayer BIBER

Road Speed / Range: 65 km/h/600 km
Armament: British 105 mm QF gun (L7A3)
Method of Ranging: The gunner has a rangefinder capable of being used either stereoscopically or coincidentally
105 mm Rounds Carried: 60 mixed loads of ADPS, HESH, HEAT and smoke
Max anti-tank range of main armament: APDS – 2,500 m. HEAT – 2,500 m. HESH – 5,500 m
Secondary Armament: One coaxial 7.62 mm MG. One roof mounted 7.62 mm MG for operation by Commander. 5,500 rounds carried
Turret Rotation: 360°, by Cadillac Gage electro hydraulic power traverse, in 12 secs
Engine: Daimler-Benz 90° V-10, 4 stroke, liquid cooled, supercharged, multifuel, compression ignition. 830 bhp at 2,200 rpm
Transmission: Four speed gearbox with hydraulic torque converter and electro-hydraulic gear selection
Steering: By tiller bar giving infinitely variable turn radii
Agility: Ground pressure – 0.86 kg/cm². Max step – 1.15 m. Max trench – 3.00 m. Max gradient – 33°. Ground clearance – 0.45 m. Power-to-weight ratio – 21 bhp/t
Water crossing ability: Unprepared wading to 1.2 m. Prepared wading to 2.25 m (turret top). Snorkel equipment permits deep water wading to 4.5 m
NBC Protection: Pressurised air conditioning and filtration system fitted
Night Vision Equipment: A white light/IR searchlight can be fitted on the gun mantlet. Gunner and driver positions can be fitted with IR viewers, and sights
Variants: The 1845 Leopards delivered to the German Army between 1965 and 1971 have now been designated Leopard **A1** after retrofitting of Cadillac-Gage main armament stabilisation system, thermal sleeve for the main armament, replaceable track pads, suspension skirts and deep wading equipment. 232 vehicles have additionally been designated Leopard **A2**s with improved ballistically protected turrets and image-intensifying night vision equipment **(1727.153)**

The 110 Leopard **A3**'s have a turret welded from rolled steel (spaced armour). From 1974, 250 vehicles, designated Leopard **A4**, with the same turret as the A3 and an integrated fire control system will be delivered to the German Army. The fire control system consists of a stabilised panoramic telescope on the commander's cupola, a computer-controlled rangefinder coupled with the stabilised main armament and a ballistic computer.

Leopard Derivatives

Armoured Recovery Vehicle – This is fitted with a crane that can be traversed through 270°, a spare engine can be carried on the rear deck and a dozer blade is mounted at the front, this can be used for dozing operations or for supporting the vehicle when the crane is being used. Performance data is similar to the basic Leopard, additional data is as follows:
Road Range: 800 km
Capacity of crane: 20 t (cable length 100 m)
Max pull of winch: single pull: 35 t (90 m of cable, double pull: 70 t

Width: 3.25 m
Fording depth: with schnorkel 4 m
Armament: 7.62 mm MG in bow of vehicle, 7.62 mm AA MG on roof

Combat Engineer Vehicle: This was developed from the ARV and has the following additional features – the dozer blade is fitted with ripping teeth for tearing up roadways etc, earth boring equipment is fitted and there is stowage space for sapper equipment.

Flakpanzer 1 (Gepard) – This is based on a Swiss development concept (**2370.131**). The Flakpanzer 1 is built by Krauss-Maffei as general contractor on a Leopard chassis with twin 35 mm cannon and two different radars, Siemens for the German Army and HSA for the Netherlands Army (**2302.153**). For these the chassis is equipped with an auxiliary power supply consisting of a 90 hp diesel engine and a 60 kw generator. Mobility is the same as the Leopard.

Self-Propelled 155 mm GCT Leopard: This has been carried out by Krauss-Maffei in collaboration with the French GIAT. The Leopard chassis has been fitted with the 155 mm turret normally mounted on the AMX-30 chassis. The turret is completely unmodified and is interchangeable between the AMX-30 and the Leopard chassis. The Leopard chassis maintains an auxiliary power supply from a 9 KW generator driven by a 20 hp multi-fuel engine. For details of the 155 mm GCT see **5574.103**.

Bridgelayer – In contrast to the normal method used to date, ie raising the bridge to unfold it and then place it in position, the Leopard bridgelayer bridge sections are slid flat one after the other and thus show as low a silhouette as possible. Performance is similar to the standard Leopard and additional data is – Range road 800 km. Length of bridge 22 m. Width of bridge 4 m. Weight of bridge 9.8 t. Capacity 50 t.

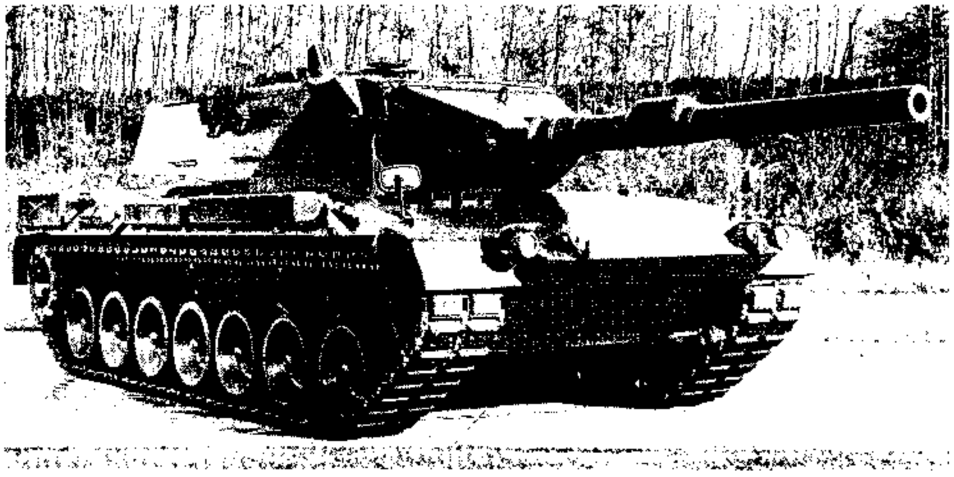
MANUFACTURER:
The main contractor is Krauss-Maffei AG, D-8000 München 50.

5114.102
LEOPARD 2 MAIN BATTLE TANK

DESCRIPTION:
The Leopard 2 has been developed by Krauss-Maffei as a replacement for the large number of M-48 tanks at present used by the German Army. A total of 17 prototypes have been built, and these are undergoing extensive trials by the manufacturers and the German Army, and one Leopard 2 has been ordered by the United States Army for early delivery; this will be used in comparative trials with American tanks.

Leopard 2 has a number of new and interesting features which will doubtless set the trend for future MBTs. It is powered by a 12 cylinder engine which develops 1500 hp and gives it a power-to-weight ratio of 30 bhp/ton which is far in advance of any MBT at present in service. It is armed with a 105 mm or a 120 mm smooth-bore gun. The suspension has been improved and is of the tube over bar type. the Leopard 2 has a better road and cross country performance than current MBTs. It is also the first post-war tank to have a turret and hull incorporating spaced armour (Leopard A3's have a turret with spaced armour), and this armour together with the heavier automotive components such as engine and transmission, have pushed the weight of the tank up to just over 50 t. Previously, when a tank had better armour the performance and mobility declined; in designing the Leopard 2 the Germans have reversed this trend, the end result being a superior vehicle.

CHARACTERISTICS:
Crew: 4 (Commander, gunner, loader and driver)
Weight: 50.5 t
Size: Length (hull) 7.73 m. Length (overall) 9.78 m (105 mm gun). Width 3.54 m (with track skirts). Height 2.45 m.
Road speed: 68 km/hr



Leopard 2 MBT with 120 mm gun

Armament: 105 mm or 120 mm smooth bore weapon developed by Rheinmetall.
Method of ranging: Optical-base rangefinder and laser rangefinder
Secondary armament: 7.62 mm co-axial MG, 7.62 mm anti-aircraft MG on loader's hatch. 2 × 4 smoke launchers either side of turret.
Turret rotation: 360° by Cadillac Gage electro-hydraulic power traverse. A stabilisation system is fitted enables the vehicle to fire on the move.
Engine: MTU 90", V-12, 4 stroke, liquid cooled, multi-fuel, compression ignition developing 1500 HP at 2,600 rpm
Transmission: HSWL-354/3 Hydromechanical with 4 forward and 2 reverse gears.
Agility: Ground pressure 0.83 kg/cm². Max step 1.15 m. Max trench 3.1 m. Ground clearance 0.50 m. Power-to-weight ratio 30 bhp/t
Water crossing ability: Unprepared wading 1.1 m. Prepared wading to 2.25 m (turret top). Schnorkel equipment permits deep water fording to a depth of 5.5 m
NBC Protection: Pressurised air condition and filtration system fitted
Night vision equipment: Passive IR night fighting and night driving equipment is fitted.

STATUS
Under test. Could enter production and service in 1976/77.

MANUFACTURER:
Krauss-Maffei AG, D 8000, München 50, Germany.

5115.102
SPÄHPANZER 2

DESCRIPTION:
The Spähpanzer 2 is an 8 × 8 armoured reconnaissance vehicle that has been developed to replace the Hotchkiss SPZ 11-2 vehicles at present used in this role. It is a very mobile vehicle and it is fully amphibious, it continues the long line of German 8 × 8 armoured vehicles. Its only drawback is that, for a reconnaissance vehicle, it is rather large and its armament is weak compared with that mounted in other recent reconnaissance vehicles.

The design dates from the mid 1960's and prototypes were completed by two main contenders (one being a consortium of companies, the other being Mercedes-Benz), a few years ago. It was announced late in 1973 that contracts had been awarded for two batches, one of 200 and one of 208 vehicles. At the present time it is not known which company will be building the production vehicles although the companies involved in their design included Mercedes-Benz, MAN, Rheinstahl, Büssing, Klockner-Humboldt-Deutz and Krupp. Deliveries are expected to commence late in 1975. The Spähpanzer (or Radspänpanzer as it is also known) uses a number of components of the new range of tactical trucks for the German

Prototype of the 8 × 8 Spähpanzer 2 vehicle

Army, ie, similar gearboxes, axles and engines. Under development is the 4 × 4 Spähpanzer which will also be fully amphibious.

CHARACTERISTICS:

Crew: 4 (commander, gunner and 2 drivers – 1 front and 1 rear)

Weight: 19 t (loaded)

Size: Length 7.34 m Width 2.98 m Height 2.50 m

Road Speed / Range: 100 km / hr / 800 km

Main armament: 20 mm Rh 202 cannon (**5600.103**)

Secondary armament: 7.62 mm anti-aircraft machine gun

Engine: Mercedes Benz Model OM 403 VA, 10 cylinder multi fuel, 390 HP

Transmission: Model ZF 4 PW 95 H 1, 4 forward and 1 reverse gears

Agility: Max step 0.6 m. Max trench 1.9 m. Max gradient 60%. Ground clearance 0.405 m

Water crossing ability: Fully amphibious, propelled in the water by two propellers at 11 km/hr

STATUS:

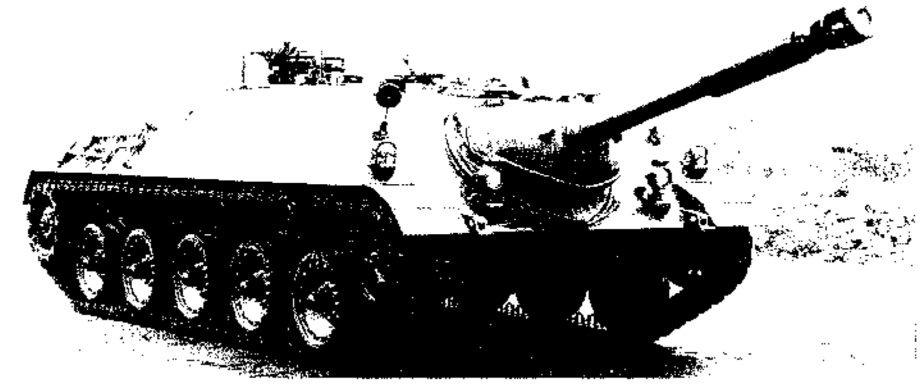
Entering production

5019.102
SELF-PROPELLED ANTI-TANK GUN
KANONE JPZ 4-5

DESCRIPTION

The Germans made extensive use of self-propelled anti-tank guns during the 2nd World War and the JPZ 4-5 is a continuation of this line of vehicle. Development of the vehicle started in the late 1950s and three series of prototypes were built and tested. After extensive trials a total of 750 vehicles were built by Rheinstahl-Hanomag and Rheinstahl-Henschel between 1965 and 1967. It uses the same chassis as the Rakete M-1966 (**5014.102**) and this common chassis was used as a basis for the development of the Marder MICV (**5013.102**) which is now in production.

In 1972 the Belgian Army placed an order for 80 vehicles: these will be assembled in Belgium. These Belgian vehicles differ from the German vehicles in that they have an improved transmission and suspension system which is based on that fitted to the Marder, and an improved and more up to date fire control system has been installed.



Kanone JPZ 4.5 self propelled anti-tank gun

CHARACTERISTICS:

Crew: 4 (Commander, gunner, loader, driver)

Weight: 26 t (laden)

Size: Height – 2.08 m. Length (hull) – 6.23 m. Width – 2.98 m

Road Speed / Range: 70 km / h / 400 km

Main Armament: 90 mm high velocity gun Bord K L/40.8 (Rheinmetall)

Rounds Carried: 51. Mixed HEP and HEAT (US pattern)

Max Useful Range: 2,000 m

Gun Traverse Limits: +15° in azimuth, +15°, −8° in elevation

Method of Ranging: By commander's estimate, with fine lay by hand-operated gunner's control

Secondary Armament: Two 7.62 mm machine guns, one coaxial with main armament, the other pintle-mounted on commander's cupola

Engine: Daimler Benz 837 Aa V-8 four-stroke diesel 500 bhp at 2,000 rpm

Transmission: Renk HSWL 123, hydraulically operated gearbox with 3 gears. A two-position transfer box selects backward or forward movement

Agility: Ground pressure – 0.75 kg/cm². Max step – 0.75 m. Max trench – 2.0 m. Ground clearance – 0.45 m. Power-to-weight ratio – 19.5 bhp/t

Night Vision Equipment: An IR target search light and driver's IR viewer can be fitted

NBC System: Yes

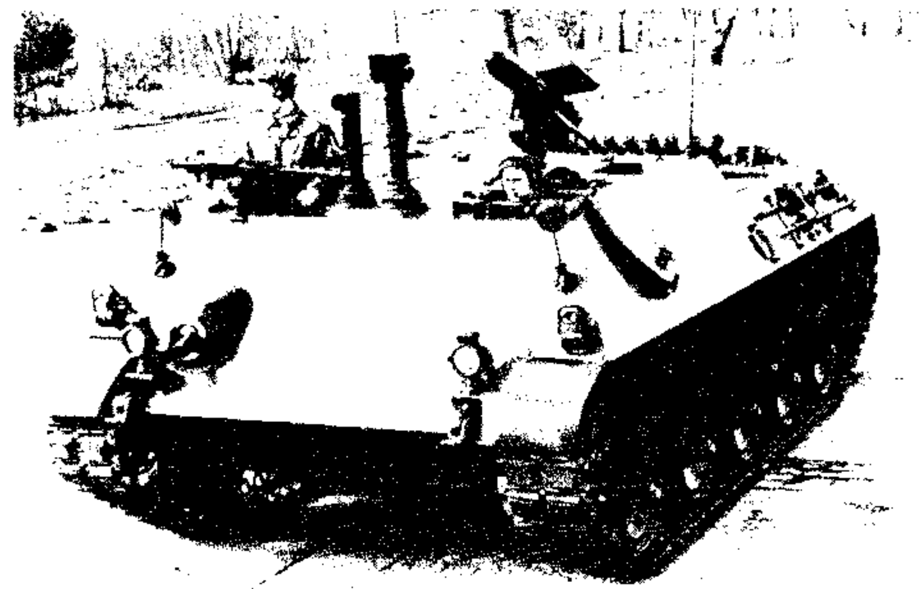
MANUFACTURER

Rheinstahl AG Sonderfertigung, 35 Kassel Henschelstrasse 2, Germany

5014.102
GUIDED WEAPON LAUNCHER
RAKETE M-1966

DESCRIPTION:

Developed in 1959 / 60 as a supplement to the JPZ 3-3 Guided Weapon Launcher based on the HS 30 chassis, it has been in service since 1963. It uses the same chassis and has a similar performance to the SP gun Kanone. It carries two SS-11 anti-tank missiles in the ready-to-fire position on launchers above the hull roof, with a further 12 carried under armour. After the first missile is fired an automatic reloading sequence begins, and a rate of fire of one missile per minute can be maintained. This vehicle increases the tank-killing range of the equipment of the Panzer Grenadier Battalions from the 2,000 m of the Kanone SP gun to the 3,200 m of the SS-11 missile.



Rakete Guided Weapon Launcher showing one of the two launcher arms extended

CHARACTERISTICS:

Crew: 4 (commander, GW controller, loader, driver)

Weight: 23 t (laden)

Size: Height – 1.98 m. Length – 6.43 m. Width – 2.98 m

Road Speed / Range: 70 km / h / 350 km

Armament: Two launchers for SS-11 guided weapons mounted above the hull roof. Two 7.62 mm machine guns, one firing through front hull plate, the other mounted in front of the commander's hatch

Rounds Carried: 14 SS-11 missiles

Traverse: Each launcher has a traverse of 90°; together they cover a total arc of 180°

Maximum Anti-tank Range: 3,200 m

Engine: Daimler Benz 837 Aa V 8 four stroke diesel 500 bhp

Derivatives: The JPZ 4-5 (**5019.102**) has the same hull as the Rakete. Trials have been carried out with a Rakete fitted with the HOT ATGW (**2212.111**)

MANUFACTURER

Rheinstahl AG Sonderfertigung, 35 Kassel Henschelstrasse 2, Germany.

Transmission: Renk HSWL 123, hydraulically operated gearbox with three gears. A two position transfer box selects backwards or forwards movement

Agility: Ground pressure 0.63 kg/cm². Max step – 0.75 m. Max trench – 2.0 m. Ground clearance 0.45 m. Power-to-weight ratio – 21.5 bhp/t

Night Vision Equipment: IR headlights and driver's IR viewer can be fitted

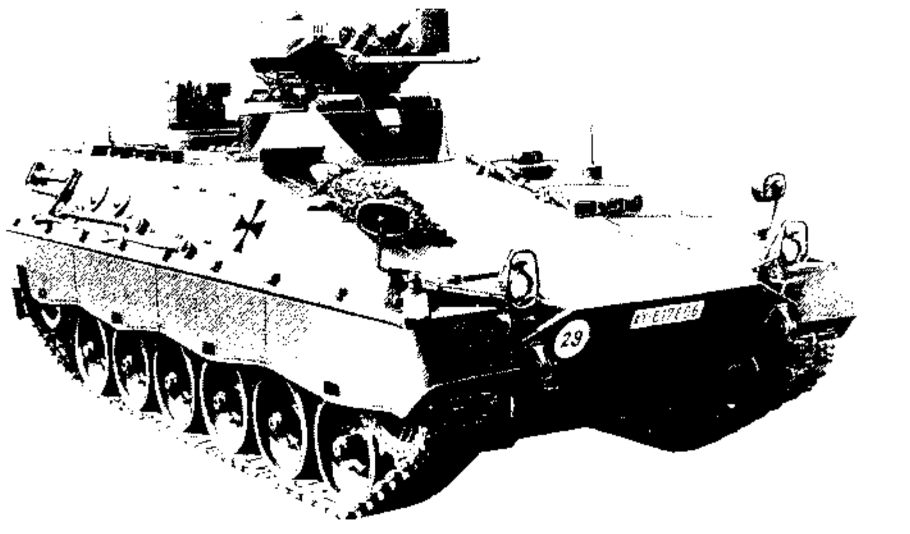
5013.102
MECHANISED INFANTRY COMBAT VEHICLE MARDER-SCHUTZENPANZER NEU M-1966

DESCRIPTION:

Designed to complement the Leopard tank in performance and mobility, the development of this vehicle was initiated at the same time as that of the Rakete GW Launcher, and the Kanone SP Gun in 1959, and many of the components are identical. Marder provides the German Army with a fast, large, hard-hitting and adequately protected MICV, which it has lacked up till now. A feature is its firepower; with a 20 mm cannon plus 7.62 mm MG mounted in a 2-man turret at the front and another 7.62 mm MG mounted in a rear cupola, and with firing ports along the side for the crew weapons, it is much more than an infantry transport vehicle. Special attention has been given to crew facilities to allow for long periods of close-down action, by heating, ventilation, noise and vibration reduction and so on.

The crew are disposed as follows. The driver is forward left, with the engine on his right. Behind him sits one infantryman. In the centre of the vehicle is the two man turret, containing the commander on the right, the gunner on the left. Six infantrymen sit back to back down the middle of the vehicle, able to use their weapons through firing ports in the roof and side. The rear gunner faces backwards and is the first man out through the rear doors, which open outwards and downwards to form a ramp.

The seats fold down to form beds, and hammocks can be slung, to allow the majority of the crew to sleep inside the vehicle at the same time. A novel feature of the vehicle is the use of a conventional steering wheel, and a truck-type gear-shift, making the task of training conscript drivers easier. Much thought has been given to make the vehicle reliable and easy to maintain. It is noteworthy that Marder is not an amphibian, since this would impose severe penalties on the design in other ways. Provision is however made for deep wading. Trials are under way of a Marder fitted with flotation bags at the sides and front of the vehicle. It is clear that this vehicle is expensive compared to other less well equipped and armed APCs. It does nevertheless represent a considerable advance on the existing APC equipment of the German Army. It is likely to be produced in very considerable numbers both for the German Army and for those other Armies that have already bought Leopard.



Marder Armoured Personnel Carrier

CHARACTERISTICS:

Crew: 10 (Commander who also commands the section when dismounted), driver, gunner for front turret, gunner for rear turret (who dismounts), six infantrymen. Exit is by rear door

Weight: 28.2 t (laden)

Size: Height – 2.95 m. Length – 6.79 m. Width – 3.25 m

Road Speed/Range: 70 km/hr/520 km

Armament: Externally mounted 20 mm cannon (Rh 202) in front turret with coaxial 7.62 mm MG. Rear cupola mounts another 7.62 mm MG. Firing ports are available for crew to use whilst closed down

Fire Control: 20 mm cannon can be aimed and fired by either of crew in the two-man turret

Rounds Carried: 1,250 of 20 mm. 5,000 of 7.62 mm

Turret Rotation: 360° (front turret only)

Engine: MTU MB 833 6-cylinder turbocharged diesel, developing 600 bhp at 2,200 rpm

Transmission: Four speed gearbox with torque converter

Steering: Hydrostatic system of double plate brakes operating onto the output shafts of the transmission unit

Agility: Ground pressure – 0.8 kg/cm². Max step – 1.0 m. Max trench – 2.5 m. Max gradient – 60% (1 in 1.7). Ground clearance – 0.43 m. Power-to-weight ratio – 21.3 bhp/t

NBC Protection: The crew compartment can be pressurised

Night Vision Equipment: An IR target searchlight can be fitted on the front turret. Commander, gunner and driver have IR viewing devices

Additional Equipment: A snorkel device to permit wading across rivers to a depth of 2 m is available

Derivatives: The 'Roland' anti-aircraft missile system is mounted on the Marder chassis in one version (**2218.131**). A mortar version with a 120 mm mortar has been developed but not placed in production. Trials are taking place with a fully stabilised turret

STATUS:

In production. Production is scheduled to end late in 1974 by which time 1926 vehicles will have been built.

MANUFACTURER:

Rheinstahl AG Sonderfertigung, 35 Kassel Henschelstrasse 2, Germany.

5008.102
ARMOURED PERSONNEL CARRIER SPZ 12-3 (HS-30)

DESCRIPTION:

The SPZ 12-3 has been the standard equipment of the German Army Panzer Grenadier Battalions since 1960, but is now being replaced by the Marder APC. The specification was drawn up in the late 1950's, at a time when the German Army was expanding rapidly and was in urgent need of an APC. To cut development time, the design was based on the chassis of an anti-aircraft gun system developed as a private venture by Hispano Suiza of Geneva, hence the designation HS 30. But Hispano Suiza did not have the manufacturing facilities to cope with volume production. It was therefore arranged that most of the order would be manufactured by the Leyland Company in England, the remainder being manufactured by the Hanomag and Henschel companies in Germany.

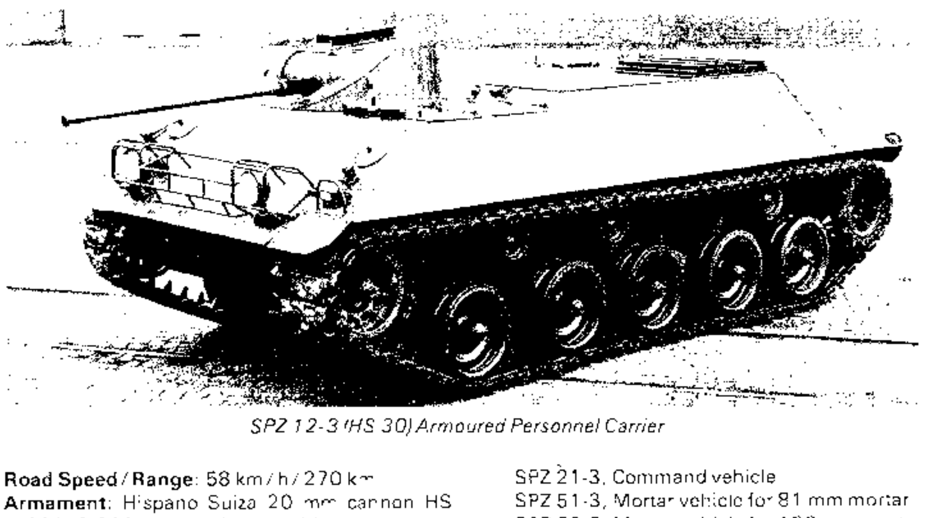
Deliveries started in 1960 and were completed (except for some variants) by 1965.

CHARACTERISTICS:

Crew: Driver plus seven infantrymen

Weight: 14.6 t (laden)

Size: Height – 1.85 m (including turret). Length – 5.56 m. Width – 2.55 m



SPZ 12-3 (HS 30) Armoured Personnel Carrier

Road Speed/Range: 58 km/h/270 km

Armament: Hispano Suiza 20 mm cannon HS 820. 2,000 rounds of ammunition

Turret rotation: 360°

Engine: Rolls-Royce 8 cylinder, petrol, spark ignition. 229 bhp

Ground pressure: 0.75 kg/sq cm

Power to weight ratio: 16 bhp/t

Derivatives:

JPZ 3-3 ATGW vehicle (SS 11)

SPZ 21-3, Command vehicle

SPZ 51-3, Mortar vehicle for 81 mm mortar

SPZ 52-3, Mortar vehicle for 120 mm mortar

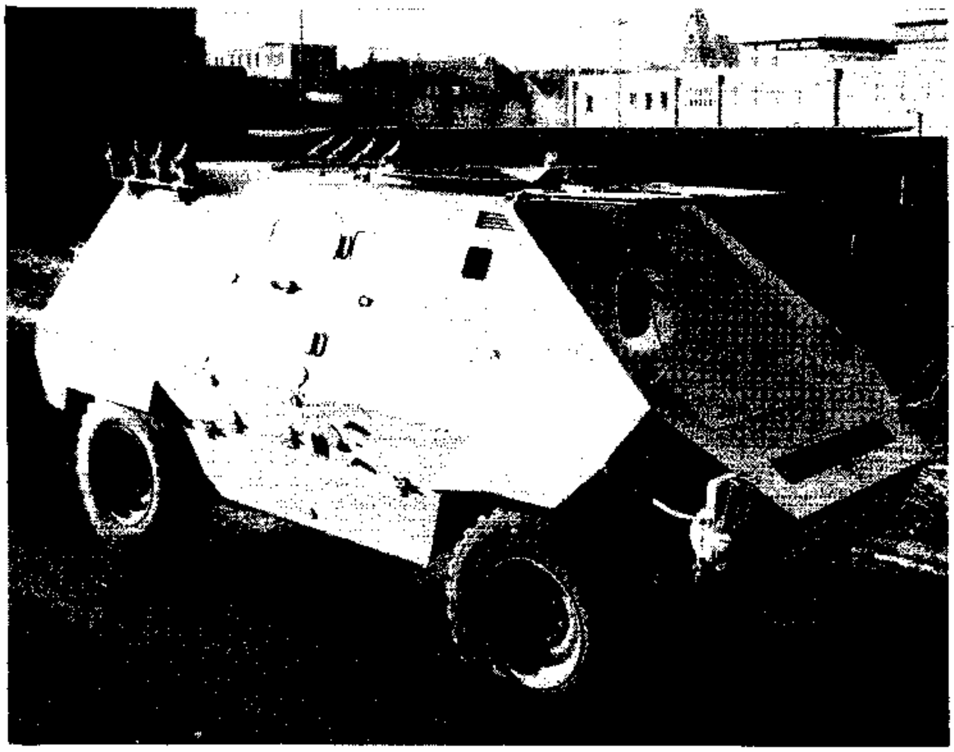
SPZ 81-3, Artillery fire control vehicle

It can also be fitted with the 106 mm recoilless rifle M-40 (**5584.103**) or TOW (**2830.111**) missile system

MANUFACTURERS IN GERMANY:

Rheinstahl AG Sonderfertigung, 35 Kassel Henschelstrasse 2, Germany.

5116.102
UR 416 ARMOURED PERSONNEL CARRIER
DESCRIPTION:
The UR 416 has been developed since 1965 and its primary role is border patrol and internal security work. The vehicle consists of a Unimog chassis on which has been fitted an armoured body. Doors are provided in the sides and rear, there are numerous firing and vision ports around the hull, and there are roof hatches. Various types of armament can be fitted according to the role required. Basic models include – ambulance, command or radio vehicle, maintenance vehicle, police vehicle with various items of equipment including obstacle clearing blade, missile vehicle with TOW or Cobra anti-tank missiles, and reconnaissance vehicles with various combinations of turret mounted 7.62 mm MG, 20 mm cannon and 90 mm recoilless rifle.
CHARACTERISTICS:
Crew: 8 (commander, driver and 6 men)
Weight: 6.3 t (loaded)
Size: Length 4.99 m. Width 2.26 m. Height 2.18 m (hull top)
Road Speed/Range: 80 km/hr/700 km
Armament: depends on role of vehicle
Turret rotation: 360°
Engine: DB-OM 352 4-cylinder diesel, 110 hp at 2,800 rpm
Transmission: Single plate dry clutch, 6 forward and 2 reverse gears, 2 speed transfer case can be fitted if required
Agility: Max step 0.55 m. Ground clearance 0.44 m. Gradient 70%
Water crossing ability: Fords to a depth of 0.55 m
NBC System: Nil

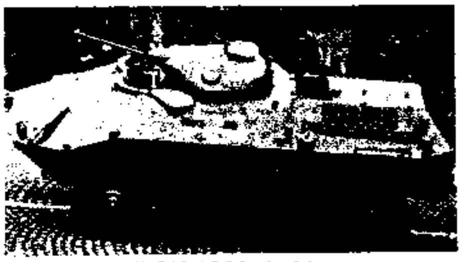


UR 416 with no armament fitted

STATUS:
In service with numerous countries in Europe, Africa, Asia and South America.
MANUFACTURER:
Rheinstahl AG Sonderfertigung, D-3500 Kassel, Germany.

HUNGARY

2189.102
FUG M-1963 (OT-65) SCOUT CAR
DESCRIPTION:
The FUG M-1963 (or OT-65 as it is also called) is the Hungarian equivalent of the Russian BTR-40P (**5037.102**). The Hungarian vehicle does however differ in a number of ways, the engine is at the rear of the vehicle and it is propelled in the water by two hydrojets. Like the Soviet vehicle it has four small wheels under the centre of the hull which can be lowered to give increased cross country performance or to assist the vehicle crossing ditches. The tyre pressures can be adjusted as required.
CHARACTERISTICS:
Crew: 5
Weight: 6.1 t
Size: Length 5.79 m. Width 2.36 m. Height 1.90 m (without armament)
Armament: one 7.62 mm machine gun
Engine: Csepel 4-cylinder in-line water cooled diesel, 100 hp at 2,300 rpm
Agility: Max step 0.47 m. Max trench 1.3 m. Gradient 60%. Ground clearance 0.305 m
Water crossing ability: Inherent amphibian. Propelled by hydrojets at 9 km/hr
Night vision equipment: Can be fitted
NBC system: Yes
DERIVATIVES:
The FUG M-1966 (also called the OT-66) is based on the FUG M-1963. The M-1966 has no belly whells and a modified glacis plate. Its turret mounts a 23 mm cannon and a 7.62 mm machine gun, and it retains the amphibious characteristics of the FUG M-1963.



FUGM-1966/OT66

STATUS:
In service with Czechoslovakia, Hungary and Poland.

INDIA

5041.102
VIJAYANTA (Victorious)
MAIN BATTLE TANK
DESCRIPTION:
The tank known as Vijayanta (Victorious) and manufactured in India was originally designed by Vickers Engineering in England. The design deliberately emphasized the use of well-proven components and ease of training and servicing and therefore lent itself readily to adoption by any country seeking to embark on the development of an armoured force. An initial quantity was sold to India in 1966 after which the Indian Government set up a factory for manufacture under licence in Madras. Over 400 have now been built in India. Details of the tank can be found below in entry number **5057.102**.
MANUFACTURER:
Avadi Company, 29 Mount Road, Madras, India.

INTERNATIONAL

5126.102
FMBT-80
DESCRIPTION:
The United Kingdom and Germany are carrying out a joint study for a tank for the 1980s called FUTURE MAIN BATTLE TANK 80. At the present time various companies and government establishments are carrying out work on this project. Late in 1973 the British Army carried out trials with some Swedish S tanks to see if this sort of tank could fulfil the required role. It has been reported that a 110 mm gun is being developed for this tank, Rheinmetall (Germany) being mentioned as being connected with the development (**2197.103**). No other information has become available at the time of writing.

ISRAEL

2009.102
ISRAELI ARMOURED FIGHTING VEHICLES
Over the years Israel has acquired, some as gifts, some as purchases and others as booty, a wide variety of armoured fighting and troop carrying vehicles. Many of these remain in service in their original form· others have been modified – sometimes quite drastically – in order to improve their combat characteristics or to maximise the number of operational AFVs available.
Somewhere in the region of a quarter of the country's total tank strength is made up of Russian-built vehicles – mainly T-55 (**5049.102**) but with a few JS III (**2882.102**) – captured from Egyptian forces. Of the remainder about half are of American origin and the other half is made up mainly of British Centurions (**5004.102**).
The entries which follow relate to a complete new development (**5062.102**) and to some modifications which have been put on a production basis in a form that has been standardised enough for the results to be regarded as new tank types.

5061.102
M4 'SHERMAN' MEDIUM TANK

DESCRIPTION:

A quantity of some 200 ex-US Sherman M4 tanks were procured by Israel in the 1950 s and were then modernised in Israel by the addition of medium velocity tank guns from France, and new Cummins diesel engines. Some of the turrets were re-equipped with the French 75 mm gun (this version being known as the Super Sherman), but the majority were converted to the French 105 mm gun (this version being known as the Isherman), firing HEAT and HE ammunition. These tanks were used extensively in the 1967 war, but their comparatively thin armour left them rather vulnerable to the 100 mm guns of the Egyptian T54/55, and casualties were heavy. Nevertheless there are believed to be still some 150 of these tanks in service with the Israeli Army. Other Sherman chassis are used to mount 160 mm mortars and 155 mm guns.

CHARACTERISTICS: M4 (105 mm)

Crew: 5 (Commander, gunner, loader, driver, co-driver). The co-driver is often omitted from the crew
Weight: 39.6 t
Size: Height 2.92 m. Length (hull) 5.93 m. Width 2.98 m
Road Speed/range: 45 km/h/240 km
Main Armament: French 1508d 105 mm gun
Method of ranging: Commander's estimate
Rounds Carried: Total of 55 mixed HE, HEAT, phosphor
Secondary Armament: Coaxial 0.3 inch Browning MG and hull mounted 0.3 inch Browning MG. Commander's externally mounted 0.5 inch MG
Turret rotation: 360°, hydraulically operated power transverse
Engine: Cummins diesel of 460 bhp
Agility: Ground pressure 0.89 kg/cm². Maximum step 0.86 m. Maximum trench 2.29 m. Maximum gradient 31°. Ground clearance 0.43 m. Power to weight ratio 11.6 bhp/t
Water crossing ability: Wading to 0.9 m

2010.102
PATTON TANK (ISRAEL)

DESCRIPTION:

One of several modifications carried out on imported or captured tanks of American, British, French or Russian origin, this alteration to the American M-48 Patton (**5056.102**) has been made by the Israeli Ordnance Corps on a scale sufficient for the resultant tank to be regarded as a separate mark.

Full details of the modification are not known, but notable features are the replacement of the M-48's 90 mm M-41 gun (**2832.103**) by the Centurion gun (**2451.103**) and the incorporation of a diesel engine in those tanks which were still fitted with petrol engines. The gun modification reduces the number of rounds carried by about 10%.

STATUS:

In service.

MANUFACTURERS:

Modification by Israeli Ordnance Corps

5122.102
ISRAELI CENTURION

DESCRIPTION:

The Israeli Army has used the standard Centurion MBT (**5004.102**) for many years and has been full of praise for the vehicle. In 1973 details were released of the Israeli Modified Centurion. It has a Continental 750 hp diesel and a General Electric hydraulic gearbox. This gives the vehicle a maximum speed of 43 km/hr, a great increase in range and a far more reliable power pack. It has also been reported that a Hughes laser rangefinder will be incorporated into the Centurion and other Israeli AFVs.

5123.102
ISRAELI T54/T55 (TI-67)

DESCRIPTION:

In the 1967 campaign the Israelis captured hundreds of Russian-made T-54 and T-55 tanks. By 1972 many of these had been modified to Israeli requirements and were either in service with the Israeli Army or held in reserve. They have the Israeli designation of TI-67. The modifications include replacing the Soviet machine guns with American machine guns, replacing the 100 mm gun by the British-designed 105 mm gun which is built in Israel, the fitting of a new electrical system as well as an air-conditioning system, and improving the fire control system. Some reports state that the tank has been fitted with a new engine, others that the Soviet engine has been retained and the cooling system modified. From most reports it would seem that the tank is not liked by its Israeli crews. In the October, 1973 campaign Israel captured some additional T-54 and T-55 tanks. In addition, large numbers of T-62s were captured from the Syrians.

5062.102
SABRA (OR TSABAR) MAIN BATTLE TANK

DESCRIPTION:

Sabra (or Tsabar – opinions differ) is the first tank designed and constructed in Israel. Built by the Israeli Army Ordnance Corps, it is said to be in the 40-ton class, mounting either the British 105 mm L7A2 gun which served the Israel armoured forces so well in the 1967 war or more probably the more recent Vickers L7A3 (**2452.103**). Other parts which are believed to have been purchased from outside Israel are an American Continental 1,000 bhp diesel engine and the hull and turret castings. It is said that the appearance of the turret is similar to that of the Russian T-55 (**5049.102**).

STATUS:

Believed to have entered service late 1972

MANUFACTURER

Israeli Army Ordnance Corps

ITALY

2005.102
MAIN BATTLE TANK LEOPARD (ITALIAN)

DESCRIPTION:

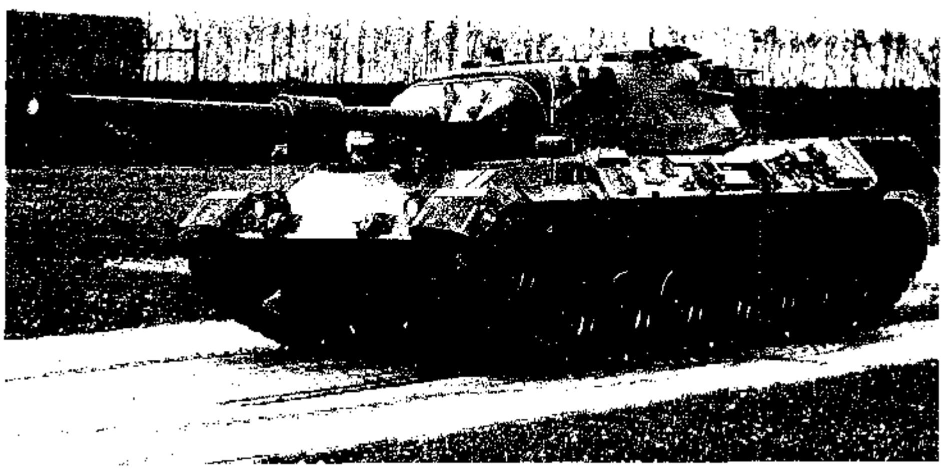
A quantity (understood to be 600) of Leopard tanks, destined for use by the Italian Army, will be produced under licence in Italy by OTO Melara with the co-operation of Fiat and Lancia in Turin.

So far as is known the tanks will not differ to any significant extent from the Leopard tanks made by Krauss Maffei in Germany (**5015.102**). OTO Melara will be making the hull, turret and gun, Fiat the engine suspension and tracks and Lancia the transmission.

Deliveries to the Italian Army were scheduled to start in the first half of 1974. 200 German-produced Leopards have already been delivered to Italy.

MANUFACTURER

Prime contractor – OTO Melara, via Valdilocchi 15, 19100-La Spezia, Italy



Leopard tank

5052.102
MAIN BATTLE TANK
M60 A1 (ITALIAN)
DESCRIPTION:

Manufactured in Italy under licence from Chrysler in the USA, 200 M60 A1 tanks are now in service with the Italian Army. As far as is known these tanks are identical in performance and appearance to the version manufactured in USA (**5024.102**).

MANUFACTURERS:

Prime contractor for the manufacture under licence was OTO-Melara, via Valdilocchi 15, 19100-La Spezia, Italy. Associated with them in this as with various other projects of this nature was the Special Vehicles Division of Fiat.

M60 AI Tanks manufactured in Italy

2006.102
MODIFIED M-47 TANK (ITALIAN)
DESCRIPTION:

The Italian Army's AFV strength includes 800 M-47 (Patton) tanks. Although no doubt it is intended that the new Leopard tanks made in Germany (**5015.102**) and under licence in Italy (**2005.102**) will replace these and the Italian-built M60 A1 tanks (**5052.102**) in front-line service, there are grounds for believing that the M-47 tanks may still have a useful role to play.

Accordingly, OTO-Melara have proposed, developed and successfully tested a modification to the M-47 which could extend the useful life of those still in service. The modification involves replacing the standard 90 mm gun by the British-designed 105 mm gun (**2452.103**) and incorporating a new diesel engine and new transmission to give a 60% increase in cruising range.

STATUS:

A prototype has been built and tested.

MANUFACTURER:

OTO-Melara, via Valdilocchi 15, 19100-La Spezia, Italy.

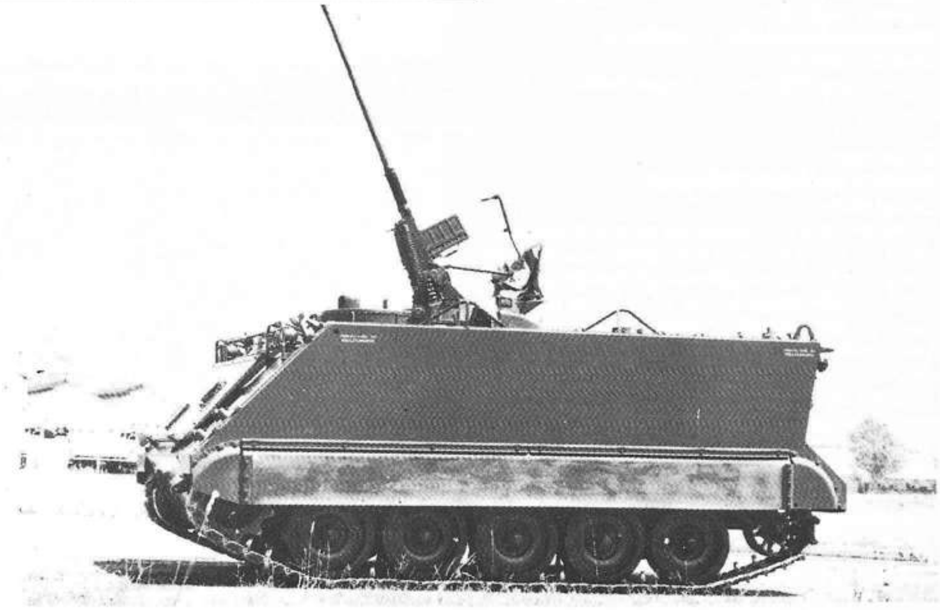
5072.102
M113 AND VARIANTS (ITALIAN)
DESCRIPTION:

In addition to manufacturing the M60 A1 main battle tank, OTO-Melara has a licence to manufacture and service the M113 Armoured Personnel Carrier and its variants from the FMC Corporation of USA. Thousands of M113s have been manufactured in Italy since 1963, in cooperation with Fiat and Lancia of Turin. Some 3,000 in various versions have been made for the Italian Army, others have been supplied to Turkey and Libya and the vehicles are still in production for several customers.

OTO-Melara have also had the contract to repair and re-build the M113 series of vehicles for all armies in Europe. The vehicles are generally identical to those of US manufacture. A variant of the M113 mounting the HS 820 20 mm cannon in a fully rotating and protected turret was developed in cooperation with Hispano Suiza of Geneva, Switzerland.

MANUFACTURER:

Main Contractor – OTO-Melara, via Valdilocchi 15, 19100-La Spezia, Italy.



M113 APC manufactured by Oto Melara, mounting the HS 820 20 mm cannon in a fully rotating and protected one-man turret

5118.102
INFANTRY ARMOURED FIGHTING VEHICLE (M-113 A1 FAMILY)
DESCRIPTION:

The Infantry Armoured Fighting Vehicle is the result of a development programme carried out by the Automotive Technical Service of the Italian Army to increase the combat effectiveness of the current M-113 A1 (**5072.102**) at present in use. It consists of the basic M-113 A1 with revised rear hull: there are a total of five firing ports above each of which is a glass block for viewing purposes. The vehicle is armed with a 20 mm or 25 mm cannon installed in a one-man turret; in addition there is a rotating hatch on the rear deck. Additional armour has been fitted – welded directly to the existing armour. The automotive components are the same as those of the basic M-113 A1.

CHARACTERISTICS:

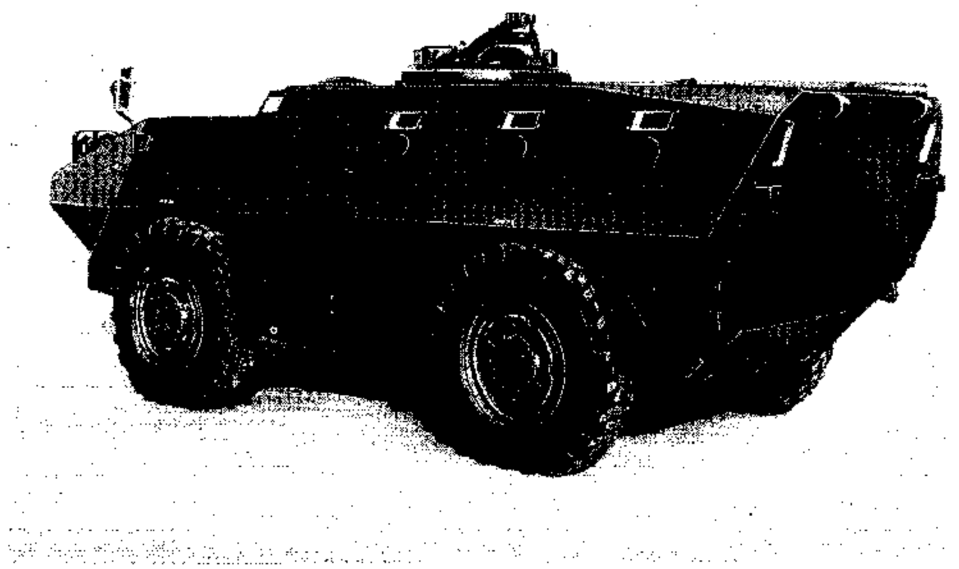
Crew: 9 (driver, gunner and 7 infantry including the vehicle commander)
Weight: 11.56 t
Size: Length 5.27 m. Height 2.55 m. Width 2.69 m
Road Speed/Range: 64.4 km/hr/550 km

OTO-Melara AIFV

Armament: 20 mm or 25 mm cannon
Agility: Ground pressure 0.56 kg/cm². Max step 0.61 m. Max trench 1.68 m Max gradient 60%. Max side slope 30%. Ground clearance 0.41 m Power-to-weight ratio 18.9 hp/t

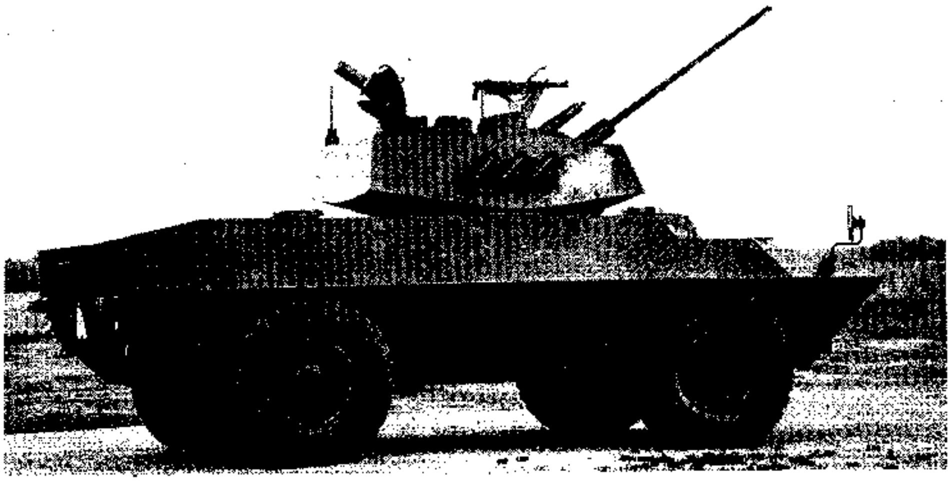
STATUS:
According to OTO-Melara this vehicle has completed its trials and is now in production. The vehicle is probably an improvement over the current M-113 but not to the extent of the new FMC AIFV (**5120.104**), the latter having improved armour and improved automotive characteristics.
MANUFACTURER:
OTO-Melara, via Valdilocchi 15, 19100-La Spezia, Italy.

5121.102
TYPE 6614 ARMOURED PERSONNEL CARRIER
DESCRIPTION:
This has been built as a prototype by Fiat and has been evaluated by the Italian Police authorities. The Type 6614 is a 4 × 4 vehicle and is fully amphibious, being propelled in the water by its wheels. It is designed primarily for the police/internal security role and for this reason it has numerous firing ports and vision blocks, at the rear is a large ramp allowing the crew to dismount from the vehicle in a very short time; in addition there are doors either side of the hull. A hatch is provided in the roof and this can be fitted with various types of armament including light machine guns.
CHARACTERISTICS:
Crew: 7
Weight: 5.9 t
Size: Length 5.16 m. Width 2.25 m. Height 1.71 m (w/o armament)
Road speed: 100 km/hr
Engine: Fiat 6 cylinder petrol, 122 hp at 5,000 rpm
Agility: Max step 0.5 m. Gradient 60%. Ground clearance 0.37 m
Water crossing ability: Amphibious
MANUFACTURER:
Fiat, Corso Marconi 10, Torino, Italy.



Type 6614 Armoured Personnel Carrier without armament

5119.102
TYPE 6616 ARMOURED CAR
DESCRIPTION:
The 6616 4 × 4 armoured car has been developed by Fiat (hull) and OTO-Melara (armament system). It is fully amphibious and air-droppable, and has been designed for a variety of roles including reconnaissance, border patrol and convoy escort duties. It has a hull of all-welded construction with the engine mounted at the rear. It is powered by a turbocharged diesel coupled with a five speed synchromesh transmission and a two speed transfer case. The wheels are fitted with runflat type tyres and have independent suspension on all wheels. Other features include power assisted steering, mechanically lockable front differential and limited slip rear differential.
The vehicle is armed with a 20 mm cannon and a co-axial 7.62 mm machine gun: on its roof is a breech-loaded smoke grenade launcher: there are six fixed smoke grenade launchers on the turret. If required the turret could be fitted with a TOW or Milan missile launcher or a 40 mm grenade launcher.
Turret rotation and weapon elevation/depression is electric/servo operated with manual operation available in an emergency.
CHARACTERISTICS:
Crew: 3 (commander, driver and gunner)
Weight: 7.4 t



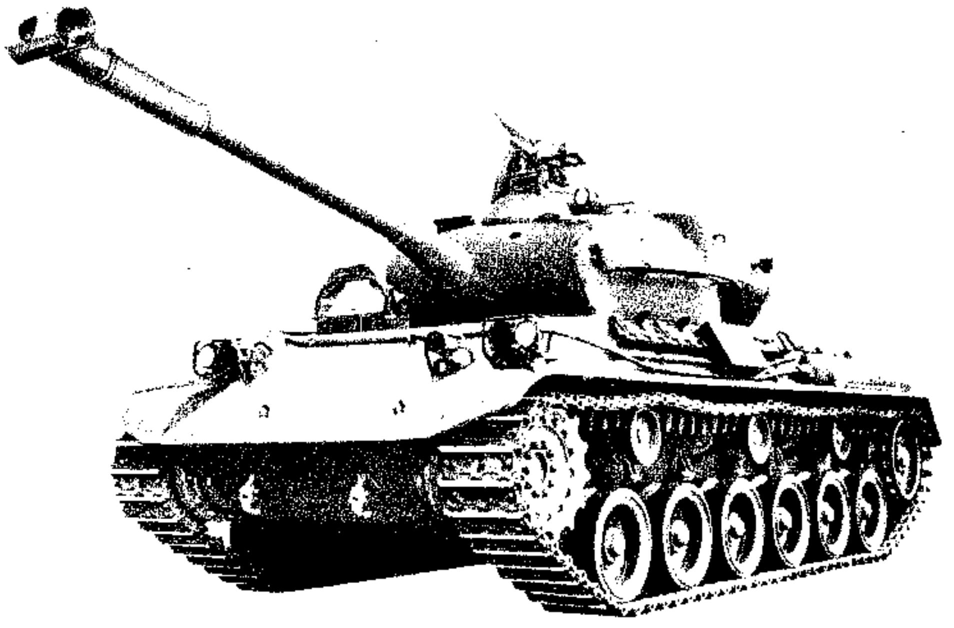
Type 6616 Armoured Car with turret-mounted 20 mm cannon

Size: Length 5.235 m. Width 2.50 m. Height 1.98 m
Road Speed/Range: 95 km/hr/750 km
Engine: Fiat 8062.22, 6-cylinder, 5.184 litres, supercharged diesel developing 147 hp at 3,200 rpm
Agility: Max step 0.45 m. Max gradient 60%. Minimum turning radius 6.5 m. Ground clearance 0.37 m
Water crossing ability: Amphibious
Self-recovery: 3 t winch
MANUFACTURERS:
Fiat, Corso Marconi, 10-Torini, Italy.
OTO-Melara, via Valdilocchi 15, La Spezia, Italy.

JAPAN

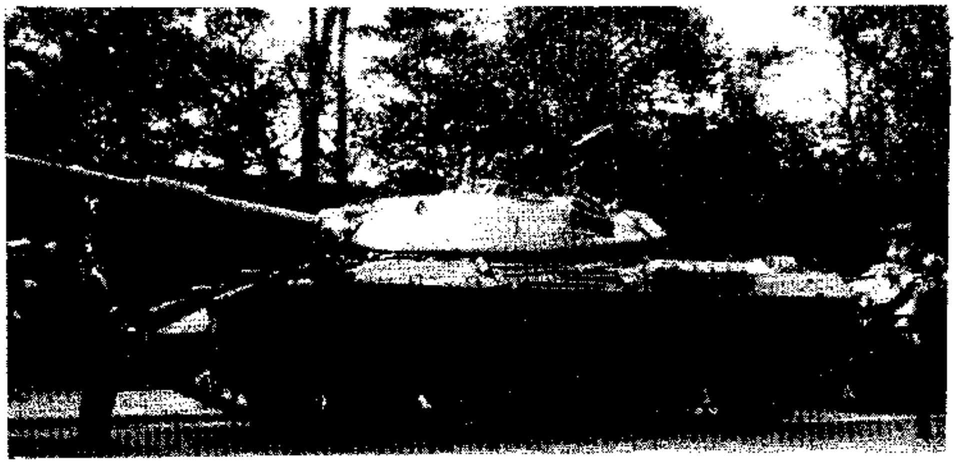
5027.102
MAIN BATTLE TANK
TYPE 61
DESCRIPTION:
When the Japanese Self Defence Forces were created in the early 1950s, all the armoured vehicles were obtained from the USA. However, as these vehicles became worn out the decision was taken to develop a range of armoured vehicles specifically designed for the requirements of the Japanese forces.
The Type 61 Main Battle Tank was one result of this decision. Its design was based more on the US M48 Tank, than on the pre-1945 Japanese Type 97 and Type 1 Medium tanks. In modifying the M48 design, advantage could be taken of the smaller stature of the average Japanese crew member compared with that of the average American – indeed it is believed that when the Japanese were using American-designed tanks their tank crews found them inconvenient in many ways. This allied to the need to match the tank to the narrow-gauge railways and light bridges found in Japan resulted in a smaller, lighter vehicle than the M48, but with equivalent firepower and mobility.
Two prototypes of this modified design were ready for testing in 1957, and after further design work two more prototypes were produced in 1960. Production followed in 1962, since when several hundred tanks have been manufactured. Notable features include a powerful V12 air-cooled diesel engine, giving this tank good mobility, a Japanese-made 90 mm gun fitted with muzzle brake and fume extractor and a simple but robust transmission system taking the drive to the front sprocket. The protection of the tank has been sacrificed to the need to keep size and weight down, and is clearly inadequate against modern anti-tank weapons.
The design of this tank is now more than ten years old and it is beginning to look out-of-date by comparison with current European and US tanks. For this reason the development of the new main battle tank ST-B (**5073.102**) is being expedited to replace Type 61 in the mid-1970s.
CHARACTERISTICS:
Crew: ½ (Commander, gunner, loader, driver)

Weight: 35 t (laden)
Size: Height (to turret top) – 2.49 m. Length (hull) – 6.30 m. Width 2 95 m
Road Speed: 45 km/h
Main Armament: 90 mm gun
Method of ranging: One metre base coincidence rangefinder
Ammunition: An APC round is used. Quantity carried not known
Secondary Armament: One .50 in MG mounted on the roof, operated by Commander. One .30 in MG coaxial
Turret rotation: 360° by power or hand traverse
Engine: Mitsubishi 12 HM 21WT V-12 air-cooled diesel. 600 bhp at 2,100 rpm
Transmission: Pneumatically assisted clutch syncromesh gearbox with 5 forward, one reverse gear. Drive taken to front sprocket
Agility: Ground pressure 0.95 kg/sq cm. Ground clearance 0.4 m. Power-to-weight ratio 17 bhp/t
Water crossing ability: No special arrangements
NBC Protection: None
Night vision equipment: IR driving lights and IR searchlights have been fitted to some tanks
Derivatives:
Type 67 Armoured Vehicle Launched Bridge
Type 70 Armoured Recovery Vehicle
Type 67 Armoured Engineering Vehicle
MANUFACTURER:
Mitsubishi Heavy Industries Ltd, Tokyo Machinery Works, 10, 2-chome, Marunouchi, Chiyoda-Ku, Tokyo, Japan.



Type 61 Main Battle Tank

5073.102
ST-B MAIN BATTLE TANK
DESCRIPTION:
The STB is the replacement for the Type 61 tank at present used by the JSDF. Development of the STB commenced in 1962 and the first prototypes were completed in 1968/69. Early models were fitted with a semi-automatic loading system for the 105 mm gun which is the British L7A3 (**2452.103**) built in Japan under licence by the Japan Steel Works.
In designing the STB the Japanese have managed to combine many of the best features of foreign tanks at present in service. The tank is fitted with a hydro-pneumatic suspension system allowing the height of the vehicle to be adjusted to suit the tactical situation, the 105 mm gun is fitted with a gun stabilisation system, and a laser rangefinder has been incorporated in the fire control system. A full range of night vision devices is fitted as also is a NBC system. If required a dozer blade can be fitted to the front of the vehicle.



ST-B Main Battle Tank (S. Yamada)

CHARACTERISTICS:
Crew: 4 (commander, gunner, loader and driver)
Weight: 38 t (laden)
Size: Length 6.6 m (hull). Width 3.18 m. Height 2.25 m (normal)
Road Speed/Range: 53 km/hr/600 km
Main armament: 105 mm gun fully stabilised
Method of ranging: Nippon Electric laser rangefinder and a Mitsubishi Electric ballistic computer
Turret rotation: 360°
Engine: Mitsubishi 10 ZF Type 21 WT 10 cylinder diesel, air cooled, developing 720 hp at 2,200 rpm
Transmission: Mitsubishi with 6 forward and 1 reverse gears. Clutch is mechanical, oil cooled
Agility: Ground pressure 0.7 kg/cm^2. Max trench 2.7 m. Max gradient 70%. Ground clearance 0.4 m (normal). Max step 1 m. Power-to-weight ratio 19.7 bhp/t
Suspension: Hydropneumatic
NBC Protection: An NBC system is fitted
Night vision equipment: IR driving and fighting lights are fitted
Deep wading: a schnorkel can be fitted
MANUFACTURER:
Mitsubishi Heavy Industries Limited, Tokyo Machinery Works, 10 2-chome, Marunouchi, Chiyoda-Ku, Tokyo, Japan.

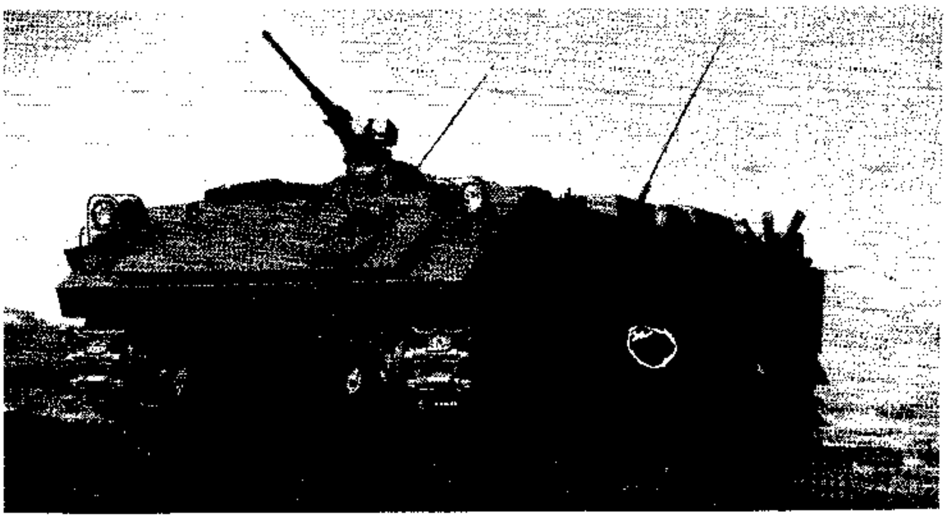
5124.102
TYPE 73 ARMOURED PERSONNEL CARRIER
DESCRIPTION:
The Type 73 Armoured Personnel Carrier (or MICV) has been designed to replace the Type 60 (**5026.102**) Armoured Personnel Carrier currently used by the JSDF. Whilst under development it was known as the Type 70. The Type 73 has a number of interesting features including a hull of aluminium armour, an NBC system and infra-red driving and fighting equipment. It is fully amphibious, being propelled in the water by its tracks: before entering the water a small trim vane is erected at the front.
Trials were carried out with two models. The first of these (SUB 1) was armed with a bow-mounted 7.62 mm MG, the roof cupola was provided with a simple mounting for a 12.7 mm MG and six smoke dischargers were mounted at the rear of the vehicle. The second model (SUB 11) also has the bow machine-gun but has a turret mounted 12.7 mm MG with three smoke dischargers either side: this model also has an IR searchlight to the left of the turret. A number of trials vehicles were fitted with rather simple firing ports either side of the hull.
CHARACTERISTICS:
Crew: 2 plus 10 infantrymen
Weight: 14 t (laden)
Size: Length 5.6 m. Width 2.8 m. Height 1.7 m (without armament)
Road Speed: 60 km/hr
Armament: 1 × 12.7 mm MG (roof) and 1 × 7.62 mm MG in bow
Engine: Mitsubishi Model V4, 2 cycle, air cooled diesel, supercharged developing 300 hp at 2,200 rpm
Agility: Max step 0.7 m. Max trench 2 m. Gradient 60%

Water crossing ability: Fully amphibious
DERIVATIVES:

None annonced so far, but some, (e.g. mortar carriers) are, without doubt, under development.

STATUS:
In production.

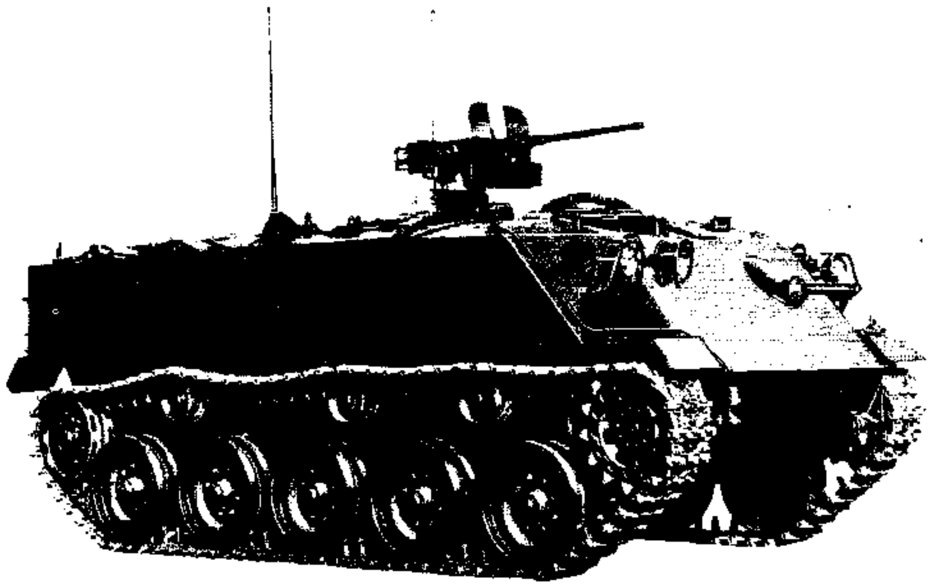
MANUFACTURER:
Mitsubishi Heavy Industries Limited, Tokyo.



Type 73 Armoured Personnel Carrier

5026.102
ARMOURED PERSONNEL CARRIER
TYPE 60

DESCRIPTION:
Two competitive prototypes to a Japanese Army specification for an Armoured Personnel Carrier were tested in 1958. One was designed by Mitsubishi, the other by Komatsu. The Mitsubishi prototype was successful but production was shared between the two companies. The Type 60 can be compared with the US M113 APC in weight and performance, but only carries a crew of 2 plus 8 infantrymen and so is smaller. In consequence it is unable to swim, and no provision has been made for a flotation screen. The commander is located at the centre front with a 0.5 in MG mounted alongside his cupola. The driver is to the right front of the commander, with a gunner on his left who fires the hull-mounted 0.30 in MG. The engine is at left centre, with the drive taken to the front sprockets. The crew members enter and leave the vehicle through two rear doors. This is an unusual lay-out, with the obvious disadvantage of the engine compartment intruding into the crew space. The vehicle has been made robust and reliable with no frills in the design. It is certainly an economical vehicle in initial and running costs.



Type 60 Armoured Personnel Carrier

CHARACTERISTICS:
Crew: 2 plus 8 infantrymen
Weight: 12 t (laden)
Size: Height 1.7 m. Length 4.85 m. Width 2.4 m
Road Speed / Range: 45 km/hr/230 km
Armament: 12.7 mm MG on pintle mounting alongside commander. 7.62 mm MG hull mounted with restricted arc of fire
Engine: Mitsubishi 8 HA-21 V-8 air cooled diesel. 220 bhp at 2,400 rpm
Transmission: Torque converter. Three forward and one reverse gear
Agility: Ground pressure 0.57 kg/sq cm. Ground clearance 0.4 m. Power-to-weight ratio 18 bhp/t
River crossing ability: Wading only
Derivatives: Two mortar carriers have been developed, one for 81 mm mortar, another for 4.2 inch mortar. Each carries a crew of 5

MANUFACTURER:
Mitsubishi Heavy Industries Ltd., Tokyo Machinery Works, 10, 2-chome, Marunouchi, Chiyoda-ku, Tokyo, Japan.

THE NETHERLANDS

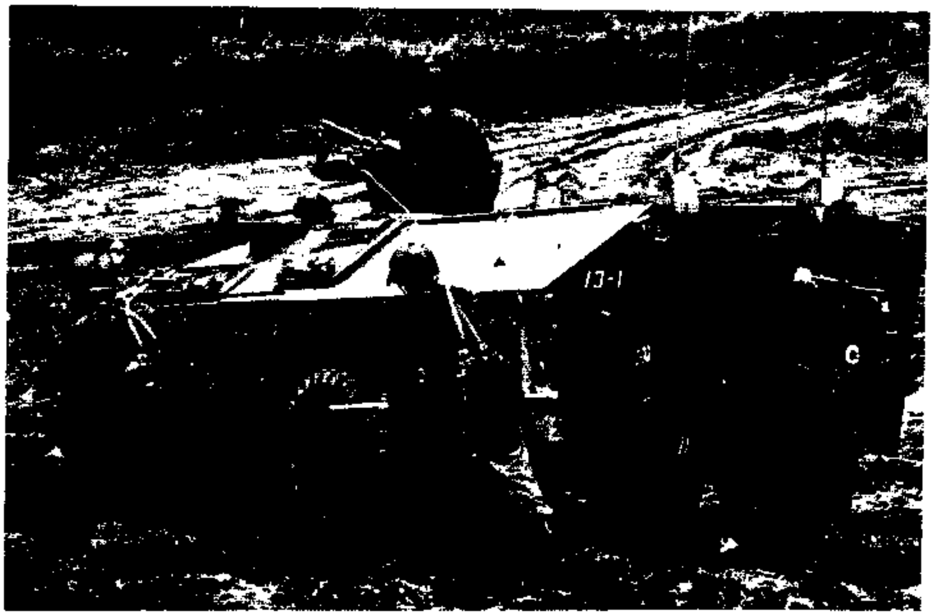
5011.102
ARMOURED PERSONNEL CARRIER
DAF YP 408

DESCRIPTION:
Developed between 1956 and 1958, using many of the components of the standard Dutch Army 3-ton truck DAF-YA 328, production of 750 vehicles for the Royal Netherlands Army was completed in 1968. It is an interesting attempt to use the reliability and economy of a truck design in an APC role. The drive from the 165 bhp diesel engine goes to six of the eight wheels, and the front four wheels steer. Cross-country performance is good, and the silence and economy of wheels makes this vehicle an attractive solution to the APC requirement. There are six variants: the details below apply to the basic group vehicle PW1-5(GR).

CHARACTERISTICS:
Crew: 12 (Driver, gunner/co-driver, 10 infantrymen)
Weight: 12 t (laden)
Size: Height 1.8 m. Length 6.23 m. Width 2.4 m
Road Speed / Range: 80 km/h/500 km

DAF YP408 Armoured Personnel Carrier

Armament: 0.50 Browning in a DAF mounting. The hatch plates are raised to the vertical position to provide some protection to the gunner
Turret Rotation: The gunner can traverse 360° by handwheel or by shoulder action
Engine: DAF DS 575, 6-line cylinders, 5.75 litres, supercharged diesel. 165 bhp at 2,400 rpm
Transmission: Drive is taken to the first, third and fourth pairs of wheels, by means of an H drive, to eliminate wheel slip. Synchromesh gearbox gives 5 forward, one reverse ratios
Agility: Max step 0.7 m. Max trench (if taken diagonally) 2.9 m. Max gradient 60%. Power-to-weight ratio 13.7 bhp/t
Water Crossing Ability: By wading, without preparation to 1.2 m
Night Vision Equipment: IR searchlight can be mounted alongside the MG. IR filters can be placed over headlamps. IR sight available for gunner. IR periscopic viewer available for the driver
Exit Doors: Two doors open at the back. Crew can also leave through hatches in the roof
Variants: PW1-S(PC) – Platoon commander's vehicle. Crew of 9. More radio equipment. Carries a portable Carl Gustav 84 mm anti-tank weapon.
PWCO – Company and Battalion Commanders Vehicle. Crew of 6. Equipped as a Command Post. Equipped with heater independent of main engine, and a pent house tent.



Troops disembarking from DAF-YP408 APC

PW-GWT – Ambulance – to carry 2 stretcher cases and four sitting patients.
PW-V – Freight carrier. Cew of 2. Can carry up to 1,500 kg of freight.
PW-MT – Mortar Tractor. Crew of 7. Developed principally to tow the 120 mm Brandt-Raye mortar. Carries 50 mortar shells.
MANUFACTURER:
Van Doorne's Bedrijfswagenfabriek BV, Geldropseweg 303, Eindhoven, Holland.

SWEDEN

5003.102
STRV 103 (S TANK) MAIN BATTLE TANK
DESCRIPTION:

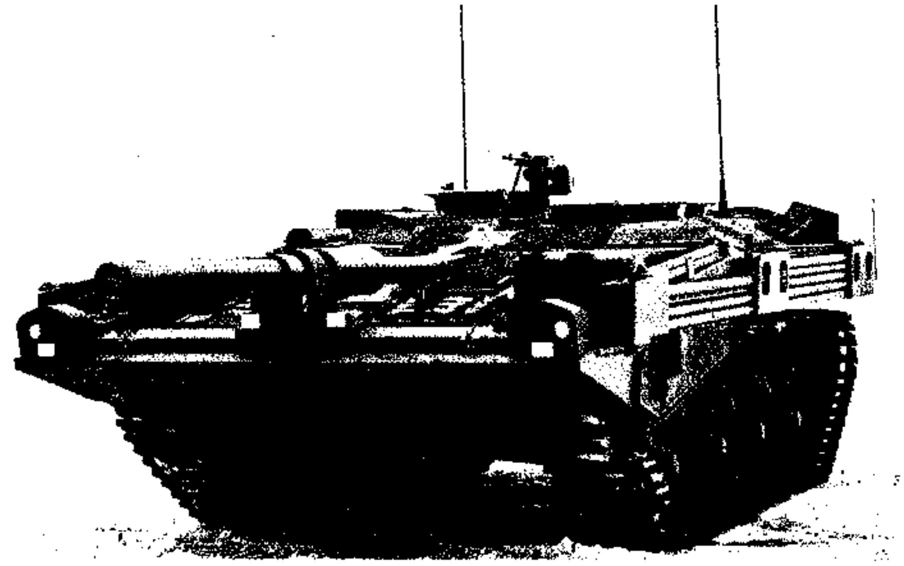
This is a highly unorthodox tank, which has incorporated more novel features into one design than any other post-1945 Armoured Fighting Vehicle. Yet this unorthodoxy has been introduced after very careful study of the requirement for AFV's in the 1970s and has not been incorporated as a technological gimmick. Paramount in the design has been the requirement to retain simplicity with reliability, and each new development incorporated has been compensated by a simplification in design elsewhere. For instance, although the fixed gun has meant complexity in the suspension arrangements for providing elevation and the steering arrangements for traverse, it has permitted automatic loading, no turret, a three man crew, duplicated gun and driving controls, and a considerable reduction in height and volume of the vehicle. The principle novel features can be listed as:

gun fixed to hull;
hydro-pneumatic suspension;
an advanced and unique steering system;
linked gas turbine and diesel engines;
duplicated gun and driving controls;
equal facility for forward or reverse driving.

Other, more minor, features of great interest to the specialist abound. There is evidence throughout this design of an unprejudiced and thoughtful examination of the established practices in tank design.

The development was initiated by a proposal put forward by the Chief Engineer of the Vehicle Division of Swedish Army Ordnance in 1956. This was followed by feasibility studies in 1958, resulting in the manufacture of two prototypes. Trials began with 10 pre-production vehicles in 1963, and full production started in 1966. The tank is now in service with the Swedish Army.

CHARACTERISTICS:
Crew: 3 (Commander/gunner, gunner/driver, rear driver/radio operator). The commander can also drive the vehicle from his position permitting one man operation of the tank in emergency. The rear driver faces backward.
Weight: 39.0 t
Size: Length (hull) 8.4 m. Length (including gun) 9.8 m. Width 3.6 m. Height 2.14 m
Road Speed/Range: 50 km/hr/390 km



STRV 103 (S tank) Main Battle Tank

Main Armament: British 105 mm gun L7A1 (**2451.105**) but with barrel 11 calibres longer than the British weapon (see **2343.103**)
Method of ranging: The original ranging machine gun method has been discarded and an optical system installed. Under development is a laser rangefinder
Rounds carried: 50 rounds mixed APDS, HE or smoke, carried in a magazine accessible through rear doors. The whole magazine can be re-loaded in 10 minutes
Rate of Fire: 10 rds/min with automatic loader. Type of round can be selected by commander or gunner. Empty cartridges are ejected through rear trap door
Method of elevation: By raising or lowering the tank suspension at back and front, the gun can be elevated between +12 deg and −10 deg. Controlled by handlebar grips by commander or gunner
Method of traverse: By slewing the tank on its tracks. Controlled by tiller boxes in commander's and gunner's positions. The process is accurate and sensitive
Secondary Armament: Two Belgian FN 7.62 mm coaxial MGs in a pod on left track guard. Sighted and laid with main armament. Can only be re-loaded by leaving vehicle. One commander's 7.62 MG for AA defence mounted to left of commander's cupola
Engines: 1 Rolls Royce K60 multifuel compression ignition 6 cylinder opposed piston. 6.57 litres 240 bhp at 3,650 rpm. 2. Boeing 553 gas turbine. 490 bhp at 38,000 rpm
Both engines are located at the front of the vehicle and are geared to a common output. Either will move the tank separately, but both are required to slew the tank for traversing the gun. Because of its better cold-start performance, the gas turbine can be used to start the diesel
Transmission: Torque converter, coupled to a gearbox with two forward and two reverse gears. Steering by a regenerative double-differential system, with an hydrostatic steering drive
Ability: Ground pressure 0.94 kg/sq cm. Max trench 2.3 m. Max gradient 30 deg (1 in 1.75).

Ground clearance 0.5 m. Power-to-weight ratio 18.7 bhp/t

Water crossing ability: Wading to a depth of 1.5 m without preparation. A swimming screen is permanently attached to each vehicle, and can be erected by the crew in 15 mins. Propulsion in water by tracks at 6 km/h

NBC Protection: No special arrangements

Night vision equipment: Driver has IR driving lights. At the present time no searchlight is fitted although trials have been carried out by fitting two Lyran illuminating shell systems to the top of the vehicle (as fitted to the British Striker **5040.102**)

Derivatives: All S tanks are fitted with a dozer blade at the front of the vehicle. First production models, the Strv. 103As did not have a flotation screen and had a less powerful engine. All Strv. 103As have now been modified to Strv. 103B standards with improved powerpack and flotation screen. Production of the S Tank was completed in June 1971. In late 1973 the British Army carried out trials with a number of S Tanks in Germany to discover if a turretless tank could meet British Army requirements for the FMBT

MANUFACTURER:

AB Bofors, S-690 20 Bofors, Sweden.

5063.102

Ikv 91 LIGHT TANK

DESCRIPTION:

The Ikv 91 is a member of the Hägglunds family of light armoured vehicles. Designed on contract for the Swedish Materiel Administration of the Armed Forces, it is a light tank intended primarily for use in an anti-tank role in terrain of most kinds and especially in marshy land and over water obstacles.

A 90 mm low-pressure gun mounted in a fully rotating power-traverse turret is designed primarily to fire HEAT rounds but can also fire HE. Comprehensive sighting and vision equipment and a fire control system including an optical rangefinder and a computer give the tank a good chance of a first-round hit on a moving target.

Mobility and fire-power have been given priority over armour; the tank's high power-to-weight ratio and low ground pressure give it good cross-country performance and it is amphibious without special preparation.

The chassis of the tank forms a fully closed unit. A bulkhead divides the driver's compartment and the central fighting compartment from the compartment for the engine and transmission.

Armour protection has been concentrated above the level of the track assembly where the probability of a hit is high. The glacis plate is given maximum possible slope. Hull sides are of double-plate type and the space between these armour plates is used for stowing of accessories and part of the diesel fuel. This combination provides good protection against HEAT.

Ikv 91 is powered by a commercial 6-cylinder turbo-charged Volvo diesel engine. This gives Ikv 91 a power/weight ratio of more than 20 bhp/ton while at the same time offering easy maintenance and good fuel economy.

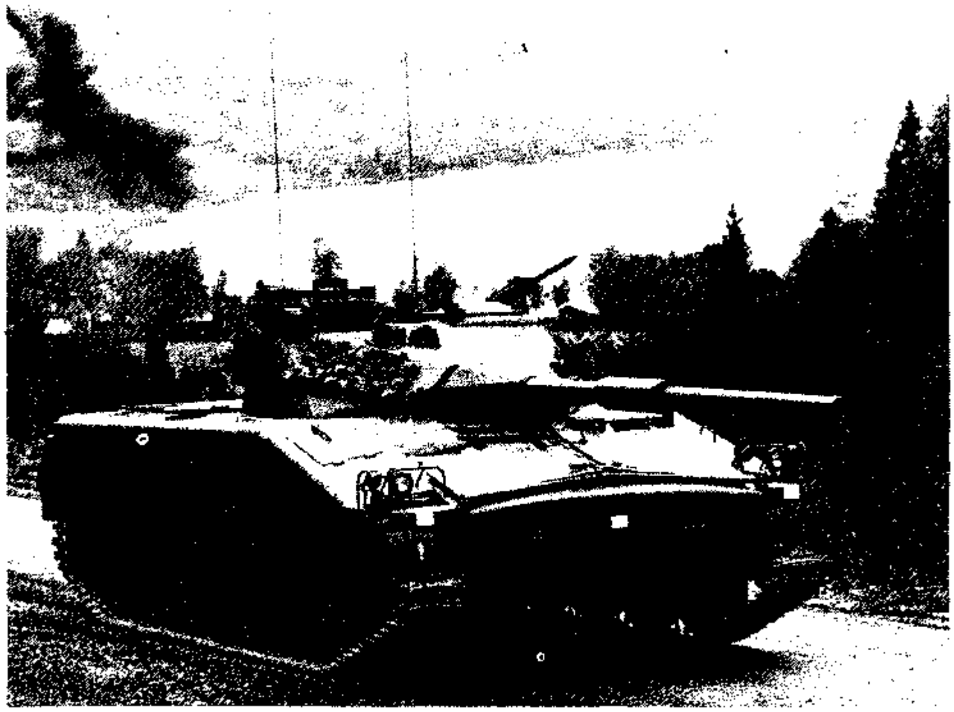
To keep length of ground contact as short as possible the big engine is mounted diagonally in the engine compartment driving the sprockets through a 58° bevel gear. The production vehicles will use an Allison HT 740 automatic gearbox which has been successfully tested as a replacement for the stick-shift gearbox used in the prototypes and Hägglunds' earlier vehicles.

The steering system is of the clutch-brake type designed to permit continuous slip-steering. The steering brakes are of the iron-to-iron disc brake type. A hydrostatic steering system is offered as an option.

Suspension of the road wheels is accomplished by individual torsion bars with shock absorbers at the front and rear road wheels on either side, giving a very smooth cross-country performance.

Track tension is operated by a hydraulic system which gives many advantages. Correct track tension under all conditions means optimal traction. Heavy strikes on idlers give no breakdown: on Ikv 91 the hydraulic system automatically readjusts track tension after a heavy strike.

For ventilation and heating of the crew compartments there are separate fans with heat exchangers in the driver's compartment and in the fighting compartment. An electric fan mounted at the air intake sucks the air through a dust-filtration system and blows it through a CBR-filter, creating a slight over-pressure in the crew compartment. Thus the crew are protected from fall-out and radio-active dust, chemical and biological agents when Ikv 91 is passing contaminated areas. The CBR-filter can be removed when dust-cleaning alone is sufficient.



Ikv91 Light Tank

ARMAMENT:

The 90 mm gun is of low-pressure type, mainly to keep the combat weight down in favour of mobility. This design with the 840 m/sec HEAT shell offers good accuracy on actual ranges of combat for the Ikv 91. Other advantages are the minimised flash and smoke and also dust screen from the ground.

90 mm ammunition types available at present are:

a fin-stabilised HEAT shell capable of penetrating the glacis platge of any battle tank;

a fin-stabilised HE shell with impact fuse.

Sixteen rounds of 90 mm ammunition are stowed in the turret and are easily available to the loader. A further 43 rounds are stowed in the chassis before and aft of the turret.

At present the gun is not stabilised in either traverse or elevation. The gun control system, however, has been designed to make it possible to achieve a fully stabilised system.

Other features of the turret are a coaxial 7.62 mm MG; smoke dischargers on the turret sides; the commander's cupola with power traverse and a 10-power binocular; the loader's cupola with 360° manual traverse and a second MG; the electrohydraulic gun control system and the ballistic computer.

Ikv91 swimming

INTEGRATED FIRE CONTROL SYSTEM:

The gun control system and ballistic computer of Ikv 91 are developed and produced by AGA Aerotronics as subcontractors to Hägglunds.

The ballistic computer operates with three different ballistics for HEAT, HE and the machine-gun ammunition.

It computes super elevation and in case of moving targets also lead angles both in traverse and elevation. Range information is usually fed to the computer from the rangefinder but it can also be fed from a manual input at the gunner's station. The computer also makes corrections for non-standard muzzle velocity, powder temperature, air conditions, cross wind and trunnion cant. Corrections are also made for jump in traverse and elevation.

The gunner's sight is a 10-power monocular with servos that deflect the line of sight in traverse and elevation according to the actual ballistic solution of the computer. When firing at moving targets the line of sight remains on the target all the time, even while lead angles and super elevation are changing due to target motions.

This is accomplished by an automatic contrarotation of the gun in opposition to the line of sight motion.

The gunner's sight can also be locked in zero-position permitting the gunner to use his reticule the ordinary way, eg. in case of power failure.

The optical rangefinder on the prototypes will be replaced on the production vehicles by a laser rangefinder, combined with the gunner's sight and binocular in the much-lowered commander's cupola.

The Bofors-produced Nd-laser is operated by the gunner and feeds range automatically to the computer.

STATUS:

Three prototypes were delivered to the Swedish

Army for evaluation between October 1970 and January 1971.

A production order for the Swedish Army was awarded to Hägglunds in March 1972 and the first production vehicles are being delivered in late 1974.

CHARACTERISTICS:

Crew: 4

Combat Weight: 15.5 metric tons

Size: Length 6.41 m (hull). Width 3.0 m. Height 2.355 m (overall)

Nominal ground pressure: 0.45 kp cm² (6.4 p.s.i.)

Performance:

Max speed road: 64 km/h

Max speed, water: 7 km/h

Range on road: 550 km

Trench crossing: 2.8 m

Maximum gradient: 30°

Angle of tilt: 30°

Power weight ratio: 22 bhp/ton

Engine:

Make: Volvo-Penta

Power at 2,200 rpm (SMMT): 330 hp

Water propulsion: Tracks

Armament:

Gun: AB Bofors

Calibre: 90 mm

Length of bore: 54 calibres

Max elevation: 15°

Max depression: −10° (0° in the rear arc)

Machine guns: 1 coaxial, 1 on loader's cupola

Calibre: 7.62 mm

Smoke dischargers: 6 barrels on each side of turret

Ammunition:

90 mm HEAT/HE: 59 rounds carried

7.62 mm MG: 4,500 rounds carried

Integrated Fire Control System: AGA Aerotronics

Gunner's Sight: Jungner Instrument AB

Magnification: × 10

Field of View: 6°

Rangefinder: AB Bofors, Nd-laser

Commander's Cupola:

Power Drive: Electrical

Binocular: Jungner Instrument AB

Magnification: × 10

Field of View: 6°

MANUFACTURER:

A. B. Hägglund and Söner, Armoured Vehicles Division, S-89101 Örnsköldsvik, Sweden.

5023.102
ARMOURED PERSONNEL CARRIER
Pbv 302

DESCRIPTION:

Pbv 302 is an APC developed by Hägglunds and in service with the Swedish Army where it has replaced the intermediate Pbv 301. It was developed on Government contract between 1961 and 1966. It has been designed to operate with the S-tank, complementing it in performance. With its power-to-weight ratio of 20 bhp/ton and its 8-ratio gearbox it has excellent cross-country performance. It carries a crew of two plus a section of ten infantrymen, and these can all use their personal weapons through the hydraulically operated top hatches. The armour is of a double-skinned variety, which is believed to give better protection weight-for-weight than homogeneous steel armour plate.

With its 20 mm cannon, and inherent swimming capability in addition to its other attributes, it is apparent that this vehicle has had a great deal of thought devoted to its design, and that it is one of the more effective APCs produced in any army in the last ten years.

CHARACTERISTICS:

Crew: Two (driver and gunner) plus a section of ten infantrymen

Weight: 13½ tons (laden)

Size: Height 2.5 m. Length 5.35 m. Width 2.86 m

Road speed/Range: 65 km/h/300 km

Armament: 20 mm automatic gun, belt or magazine feed. Rate of fire 500 rds/min

Ammunition carried: 505 rounds

Ammunition types: 20 mm HE quick fuse tracer shell, and armour piercing tracer projectile

Turret rotation: 360°, by handwheel, in approximately 12 secs

Sighting method: Periscopic sight, with a ring sight for use against aerial targets

Engine: Volvo-Penta supercharged 6 cylinder flat diesel, located under the commander, driver, and gunner's positions in the centre of the vehicle. Capacity 9.6 litres. 280 bhp at 2,200 rpm

Transmission: Mechanical, manual gearbox with double dry plate clutch. Steering by clutch and brake with driver's tiller bars (an unusual arrangement in a modern AFV). 8 forward gears, two in reverse

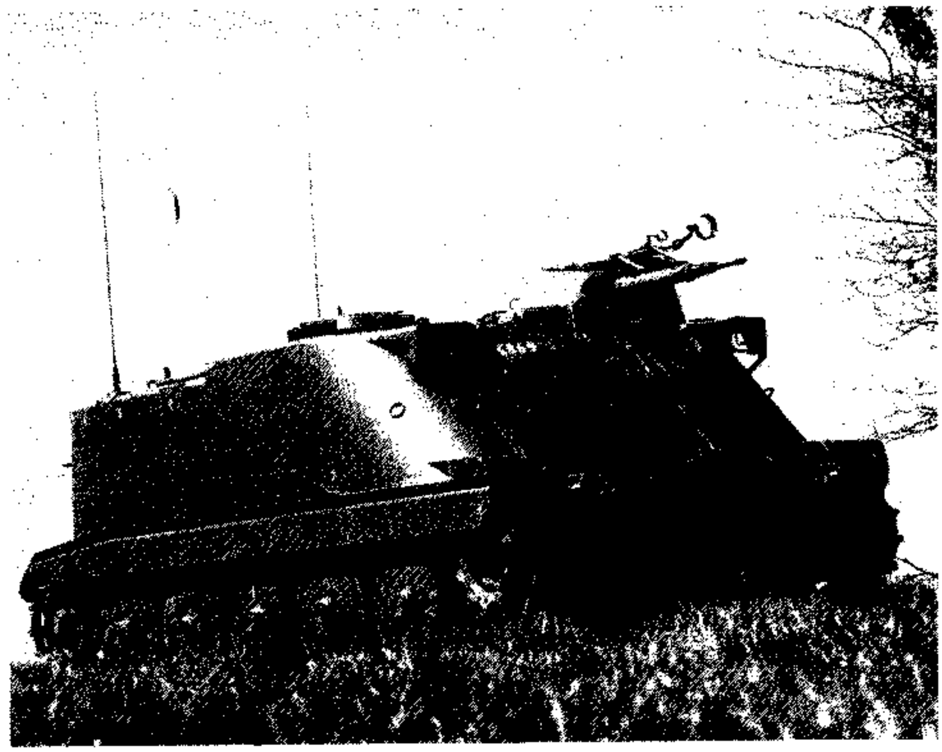
Agility: Ground pressure 0.6 kg/cm². Max step 0.6 m. Max trench 1.50 m. Ground clearance 0.4 m. Power-to-weight ratio 20 bhp/ton

Water crossing ability: Inherent swimming capability. Front wash plate is lowered as vehicle enters the water. Propulsion by tracks. Speed 8 km/h

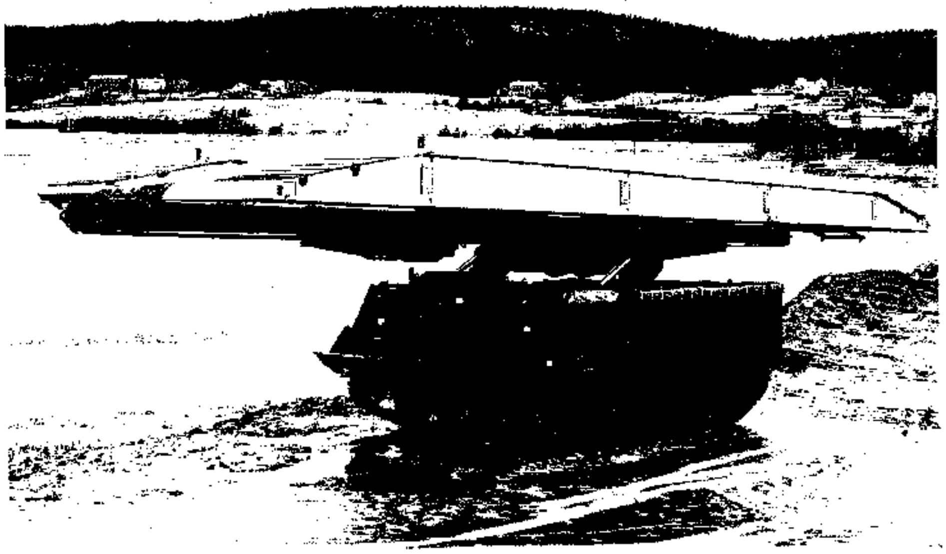
Exit: Exit for the section is by two large doors in the back opening on vertical hinges with a central pillar. Exit can also be made through the top hatches

DERIVATIVES:

Alternative 'fits' of the same vehicle include Armoured Command Vehicle, Armoured Observation Post Vehicle, Armoured Fire Direction Post Vehicle.



Pbv 302, Armoured Personnel Carrier



The Brobv 941 amphibious bridgelayer, based on the Pbv 302 chassis, and capable of laying a bridge of classification 50t across a 15 m gap in 5 minutes

Product Improved Pbv 302

Hägglund and Söner have suggested that the basic Pbv 302 could be improved by the following: (a) Replacing the 20 mm cannon with the 25 mm Oerlikon gun (**5586.103**); (b) Fitting an automatic Allison HT 740 gearbox; (c) Fitting the hydrostatic steering system that has been fitted to the Bgbv 82 and Brobv 941 vehicles; (d) replacing the engine with the Volvo THD 100C – this develops 310 hp against 280 hp of the current engine; (e) Sloping the sides of the vehicle and fitting firing ports and vision blocks. This would enable the crew to fire their weapons from within the vehicle. Trials with the Allison automatic gearbox have already been carried out.

Two heavier vehicles, based partly on the same chassis, are an amphibious recovery vehicle Bgbv 82, weighting 26 t, with hydraulic winch, hydraulic hoist and dozer blade, and an amphibious bridgelayer Brobv 941, weighting 28 t, able to lay a 15 m aluminium bridge, of 50 t classification.

The Ikv 91, 15 t amphibious light tank is partly based on the same chassis (**5063.102**).

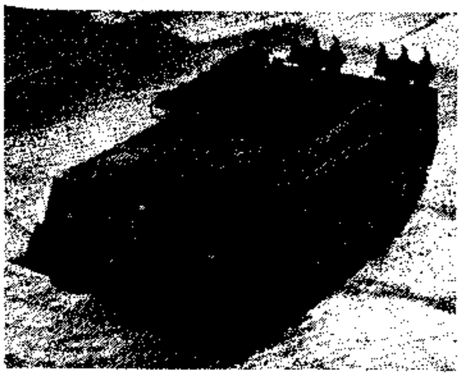
STATUS:

Delivery of Pbv 302 to the Swedish Army was completed on 30th December 1971. In addition to the basic carriers a small number of Slpbv 3021 armoured command vehicles, Epbv 3022 armoured observation post vehicles and Bplpbv 3023 armoured fire direction post vehicles have also been supplied.

The first production armoured recovery vehicle entered service with Swedish armoured units in the spring of 1972. Production of the bridgelayer started later in 1972.

MANUFACTURER:

AB Hägglund and Söner, S-89101 Ornsköldsvik, Sweden.



Bgvb amphibious recovery vehicle

MAIN BATTLE TANK PZ 61

DESCRIPTION:

Until 1958 the Swiss Army had always bought in foreign tanks, and is still equipped with some AMX13s bought in 1951, and Centurions, Mk 3, Mk 5 and Mk 7, bought between 1955 and 1960. However the decision was taken in 1951 to build in Switzerland a tank that was suited to both the military and the geographical situation of the country. The first run of 10 prototypes known as Pz 58 were manufactured in 1958, and were armed with the 90 mm gun. But by 1961 it was decided to manufacture a tank based on the Pz 58 chassis, but using the British 105 mm gun. This tank is known as Pz 61, and 150 were manufactured between 1964 and 1966.

Apart from the gun (British, but manufactured under licence in Switzerland), and the power plant (German) the design and manufacture are wholly Swiss. The tank is unusual in having a cast steel hull, and has an interesting suspension system employing Belleville washers in place of more conventional springs. Light alloys have been used in the construction wherever possible so as to permit the heavy armouring of critical areas. In addition to the protection provided against atomic blast by the armour a positive pressure is maintained inside the tank to keep out radioactive particles. The tank has an excellent cross-country performance and is a formidable defensive vehicle, which is said to be reliable and popular in service.

CHARACTERISTICS:

Crew: 4 (commander, gunner, loader, driver)
Weight: 38 tons
Size: Length (hull) 6.78 m. Height 2.73 m. Width 3.05 m
Road Speed/Range: 50 km/h/300 km
Main Armament: British 105 mm L7A2 gun (**2452.103**)
Method of ranging: 155 cm base coincidence rangefinder
Rounds carried: APDS and HESH
Secondary Armament: Coaxial 20 mm Oerlikon cannon plus one 7.5 mm MG mounted on loader's hatch for AA defence

Pz 61 Main Battle Tank

Turret rotation: 360°, power traverse
Engine: Daimler Benz MB 837, V8 Diesel, 29.8 litres water cooled, 630 bhp at 2,200 rpm
Transmission: Hydraulic multi-plate clutch. Gearbox has six forward, two reverse gears electrically selected
Agility: Ground pressure 0.85 kg/sq cm. Max step 0.75 m. Max trench 2.60 m. Max gradient 70% (1 in 5.5). Power-to-weight ratio 17 bhp/ton
Water crossing ability: Unprepared wading to depth of 1.12 m

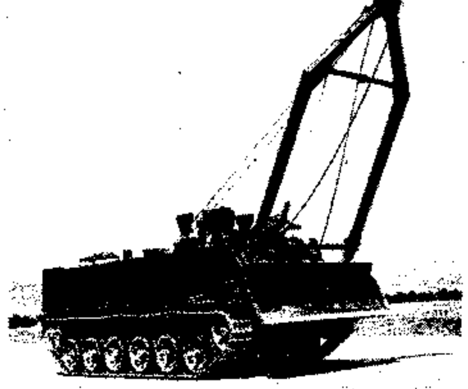
DERIVATIVES:

A prototype bridgelayer was constructed on a Pz 61 chassis, but this has now been superseded by one mounted on the later Pz 68 chassis.

An armoured recovery vehicle version is in Swiss Army service.

MANUFACTURER:

Eidgenössische Konstruktionwerkstätte, Thun, Switzerland.



Entpannungspanzer (Ent. Pz) 65 armoured recovery vehicle on Pz 61 chassis

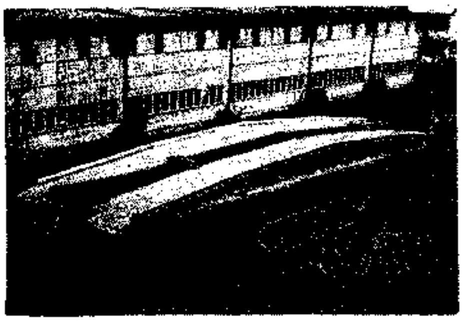
5076.102
MAIN BATTLE TANK PZ 68

DESCRIPTION:

An improved version of the Pz 61 (**5031.102**) the Pz 68 was introduced in 1968. The main differences between it and the Pz 61 are increased maximum speed and operating range, tracks fitted with rubber blocks and important changes in the armament system which include stabilising the 105 mm gun in both elevation and azimuth and replacing the 20 mm coaxial cannon by a 7.5 mm machine gun.

CHARACTERISTICS:

Crew: 4 (commander, gunner, loader, driver)
Weight: 39 tons
Size: Length (hull) 6.8 m. Height 2.72 m. Width 3.1 m
Road speed: 55 km sh
Range: 350 km
Main Armament: 105 mm 51 calibre stabilised gun
Method of ranging: 155 cm base coincidence rangefinder
Elevation/Depression: +21°/−10°
Turret rotation: Almost 360°, power traverse
Secondary Armament: Two 7.5 mm MG, one coaxial, the other on loader's hatch
Engine: Daimler-Benz Type 837 V-8 diesel, 660 bhp at 2,200 rev/min
Transmission: Hydraulic multi-plate clutch. Gearbox has six forward and six reverse gears
Agility: Ground pressure 0.85 kg/cm². Max step 0.75 m. Max trench 2.60 m. Max gradient 70% (1 in 5.5). Power-to-weight ratio 17.4



Brü. Pz 68 Bridgelayer on Pz 68 chassis

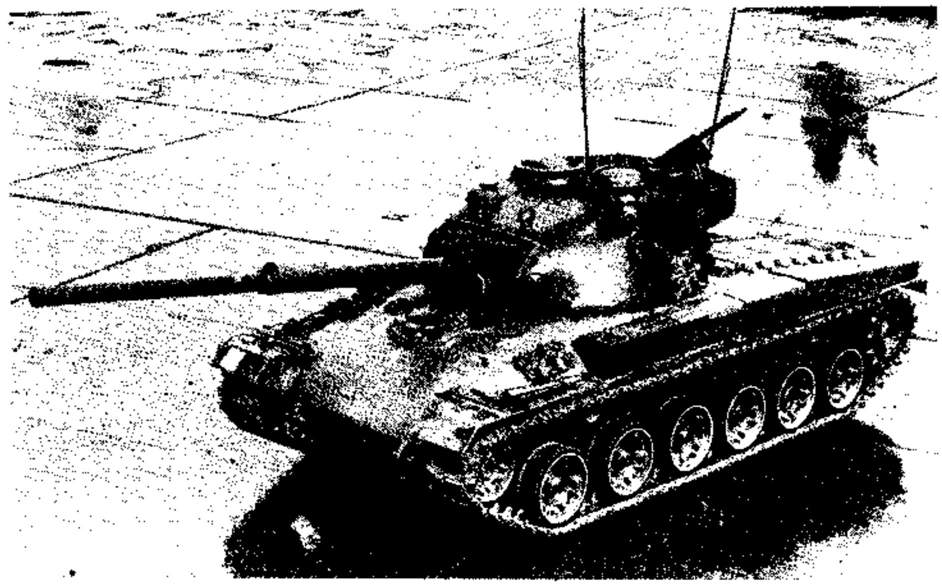
bhp/ton
Water crossing ability: Unprepared wading to 1.12 m

DERIVATIVE:

A bridgelayer with an 18 metre span capable of carrying 50 tons (60 in an emergency) is in service. Known as the Brü Pz 68 it has the same mobility as the Pz 68 and weighs 45 tons. In 1972 a prototype was shown of the Panzer-Kanone 68. This consists of a Pz 68 chassis with a turret mounting a 155 mm howitzer. This has a range of at least 30 km. It is also reported that an anti-aircraft vehicle based on the Pz 68 is under development, it is not known if this will be armed with guns or missiles.

MANUFACTURER:

Eidgenössische Konstruktionwerkstätte, Thun, Switzerland.



Pz 68 Main Battle Tank

5077.102
PUMA AMPHIBIOUS ARMOURED PERSONNEL CARRIER

One of a family of armoured amphibious wheeled vehicles designed by Mowag, the Puma is the middle one in size and payload. Weighing about 16 tons including a payload of some 4 tons it is a 6 × 6 vehicle that can be armed with a variety of weapons and can carry up to ten armed men in addition to the driver. The suspension and wheel drive mechanism gives the vehicle good cross-country performances and a useful waterborne performance is achieved by propellers driven from the rear axles.

NBC protection is provided for the crew who have access by overhead hatches and rear doors. The rear doors also contain special firing ports for use with 9 mm submachine guns.

CHARACTERISTICS:

Crew: 11 (driver plus 10)
Weight: 16 tons
Size: Length 6.75 m. Width 2.6 m. Height 2.08 m to top of hull (about 3 m to top of weapon mounting)
Road speed: 80 km/h
Cross-country speed: About 42 km/h
Water speed: 12 km/h
Road range: 500 km
Armament: Alternatives: turret-mounted 20, 30 or 40 mm cannon: trunnion-mounted 20 mm cannon; twin 80 mm rocket launchers; mortar. With all but the turret mounted cannon a remotely operated 7.62 mm MG mounting can be incorporated as secondary armament
Engine: Mowag M8DV V-8 diesel. 365 bhp at 2,000 rev/min

MANUFACTURER:

Mowag Motorwagenfabrik AG, Kreuzlingen, Switzerland.

Mowag Puma with 20 mm turret-mounted cannon

5045.102
TORNADO MECHANISED INFANTRY COMBAT VEHICLE

DESCRIPTION:

Developed as a private venture in response to a Swiss Army specification, the Tornado is a tracked armoured personnel carrier that is designed primarily for mounted combat or reconaissance use, enabling its crew to fight while enjoying a measure of NBC and armour protection.

According to the type of turret fitted the vehicle carries one or two men in the turret and has firing positions for six other infantrymen. Two basic turret types are available, one with a trunnion-mounted weapon and the other an enclosed turret with an internally-mounted weapon. The main armament is either a 20 mm or a 25 mm automatic gun; for secondary armament two remote control units for 7.62 mm machine guns are mounted at the rear. The four gun-ports in the hull are designed for use with 9 mm sub-machineguns and can be used effectively up to ranges of 100 metres or so.

To minimise internal space – and hence operational versatility – the engine, gearbox, steering gear and cooling system are made as a single subassembly and elastically mounted in the hull, power being taken directly from the differential gear to the driving sprockets. The power train can readily be removed from the vehicle for field maintenance and is separated from the crew area by an NBC partition. The NBC protection system produces a slight over pressure inside the hull.

Main access to the crew compartment is from the rear, but emergency escape hatches are also provided in the floor of the hull.

CHARACTERISTICS:

Crew: 9-10 (commander, driver and 7-8 infantrymen)
Weight: (Laden) about 21 tons
Dimensions: Length 6.1 m. Width 3.1 m. Height 1.8 m

Mowag Tornado with one-man turret and trunnion-mounted 25 mm gun

Armament: 20 or 25 mm cannon, trunnion or turret mounted plus two 7.62 mm MGs
Road speed: 65 km/h
Range: 500 km
Engine: Mowag M8DV TLK V-8 water-cooled CI 430 bhp at 2,000 rev/min
Transmission: Either Allison CLBT 5860 torque converter or Mowag M 150-6S synchromesh
Agility: Ground pressure 0.62 kg/cm². Max step 0.9 m. Max trench 2 m. Ground clearance 0.4 m. Power-to-weight ratio about 20 bhp/ton
Water crossing ability: Unprepared wading to 1.2 m. Prepared to 1.7 m

Mowag Motorwagenfabrik AG, Kreuzlingen, Switzerland

THE UNITED KINGDOM

5004.102
CENTURION MAIN BATTLE TANK

DESCRIPTION:

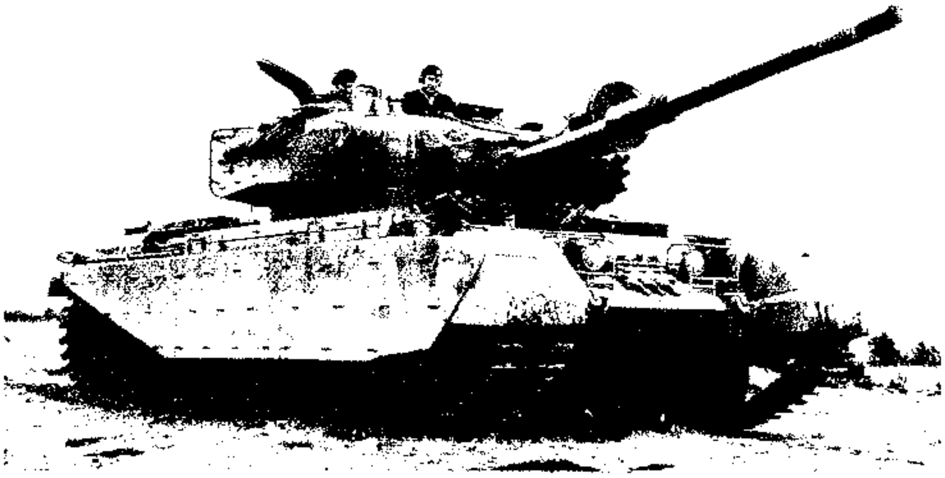
Centurions were the standard British Army tanks for over 20 years. First brought into service in 1945, they have seen service in Korea, Suez, the India/Pakistan war, the Israel/Arab wars of 1967 and 1973 and with the Australians in Vietnam. As they have been replaced in British Army service by Chieftain, they have found a ready market, particularly in the Middle East.

Export sales of this tank from UK have amounted to a total of some 3,000 tanks. Some of the major customers have been Egypt (30), Switzerland (320), Israel (400), Lebanon (40), Denmark (100), Jordan (40), Australia (200), Sweden (80), South Africa (100), Iraq (55), India (220), Netherlands (600) and Canada (60). They are currently in service in Australia, Canada, Denmark, Iraq, India, Israel, Jordan, Kuwait, Lebanon, Netherlands, South Africa, Sweden and Switzerland. The original design has gone through 13 Marks, up-gunning, up-armouring, improving fire control and introducing night vision aids in stages. The principal Marks still in service are:

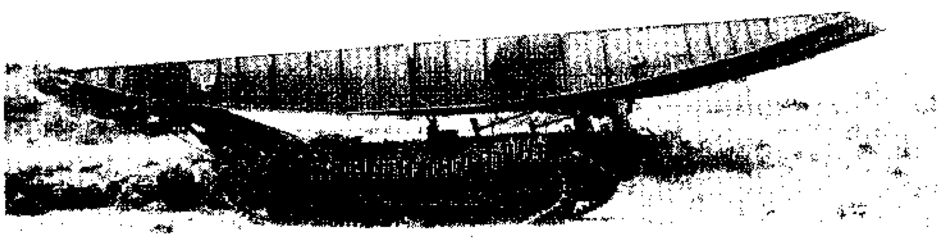
- Mk. 3 – 20 pdr gun.
- Mk. 5 – 20 pdr gun. Mk. 5/1 up-armoured, Mk. 5/2 105 mm gun.
- Mk. 6 – 105 mm gun, up-armoured and additional fuel. Mk. 6/1 IR equipment. Mk 6/2 ranging MG.
- Mk 7 – 20 pdr gun, hull re-designed to improve fuel capacity and stowage of ammunition. Mk. 7/1 up-armoured, Mk. 7/2 has 105 mm gun.
- Mk. 8 – 20 pdr gun with fume extractor. Mk 8/1 is up-armoured and Mk. 8/2 has 105 mm gun.
- Mk. 9 – is Mk 7 with 105 mm gun and up-armoured. Mk. 9/1 has IR equipment. Mk 9/2 has ranging MG.
- Mk. 10 – is Mk. 8 with 105 mm gun, up-armoured. Mk. 10/1 has IR equipment. Mk 10/2 has ranging MG.
- Mk. 11 – Mk 6 with Infra Red (IR) and RMG.
- Mk. 12 – Mk 9 with IR and RMG.
- Mk. 13 – Mk 10 with IR and RMG.

Numerous variants of these marks exist in the form of specialised versions for a variety of tasks. Centurion has proved to be among the most versatile and successful tank designs ever developed.

CHARACTERISTICS (Mk. 13):
Crew: 4 (commander, loader, gunner, driver)
Weight: 52 tons (laden)
Size: Height 2.97 m. Length (hull) 7.8 m. Width 3.39 m
Road Speed/Range: 34 km/h/190 km
Armament: 105 mm L7A/2 51 calibre with fume extractor **(2451.103)**
Method of ranging: Coaxial .50 in Ranging Machine. Gun firing in bursts of 3 rounds at 4 set ranges between 600 m and 1,800 m
Elevation: + 20°. Depression: −10°
Rounds carried: 64 mixed APDS and HESH
Turret rotation: 360 degrees in 26 secs
Engine: Rolls-Royce Meteor petrol engine. V-12, 650 bhp at 2,550 rpm



Centurion Mk 13 with 105 mm L7O2 standard NATO gun. The infra red searchlight and filtered headlamps are clearly visible



Centurion Bridgelayer (Christopher F. Foss)

Transmission: Non-synchromesh Merritt Brown gearbox giving 5 forward, 2 reverse ratios
Agility: Ground pressure – 0.94 kg/sq cm. Max step – 0.9 m. Max trench – 3.4 m. Max gradient – 35 degrees. Ground clearance – 0.4 m Power-to-weight ratio – 12.7 bhp/ton
Night vision equipment: Philips IR equipment including 1 kW searchlight, driver's viewer and gunner's sight can be fitted
Additional equipment variants: Snorkelling equipment has been fitted experimentally. The principal variants based on the Centurion chassis are: Dozer tank; Armoured Recovery vehicle; Bridgelayer (15.8 m bridge); Artillery observation tank, Engineer vehicle (in various forms); Beach Armoured Recovery Vehicle (will wade up to 3.35 m depth). A large number of other locally adapted variants exist.

PRODUCT IMPROVED CENTURION

Vickers are the Design Patentees of the Centurion and built about 1,000 of them. They are currently offering a retro-fit package to bring the Centurion up to modern tank standards. Vickers can carry out this programme or it can be carried out in the customer's own workshops. The modifications include a modern diesel power-pack comprising a GM V-12 engine, TN 12 gearbox as fitted to Chieftain, modernised gun control equipment, laser range-finder, new commander's cupola, modern ventilation system and passive night vision equipment. Vickers have already received an order to retro-fit Centurions for at least one overseas customer.

MANUFACTURER:

The majority of the Centurions produced were manufactured in Royal Ordnance Factories.

5006.102
CHIEFTAIN MAIN BATTLE TANK

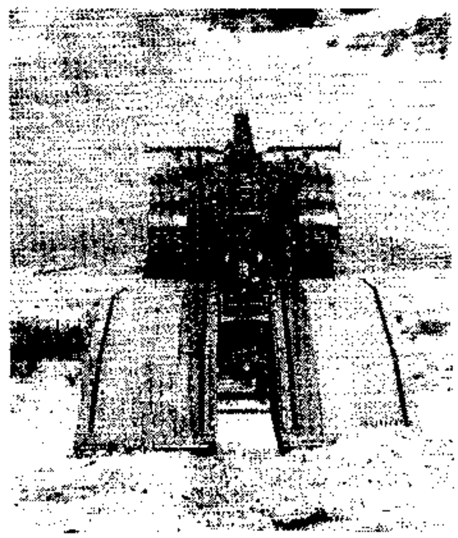
DESCRIPTION:

Design of the Chieftain MBT commenced in the 1950s and the first prototype was completed in 1959. In 1963 the Chieftain was accepted for production and two production lines were set up at the ROF Leeds and Vickers Limited, Elswick. The first model was the Mk. 1 which was used for training purposes and was followed by the Mk 2 in 1966. The Mk 2 has a 650 bhp engine. The Mk 3 entered service in 1969 and has an improved auxiliary generator, new cupola and improved main engine. Mk 3/G (prototype), Mk. 3/2 and Mk. 3/S have improved turret air breathing. Mk 3/3 has an improved engine, new air cleaner system, extended range (2,500 m) ranging machine gun and a Barr and Stroud LF2 laser rangefinder. Mk. 4 was for trials purposes only. The Mk. 5 is a development of the Mk. 3/3 and has an improved engine and more ammunition capacity. The Mk. 6 will be the Mk. 2 modified to Mk. 5 standard and the Mk. 7 will be the Mk. 3 and Mk. 3/3 brought up to Mk. 5 standards. Mk. 1s that are used for training will also be modified in due course with a new engine but not the improved FCS. GEC-Marconi Electronics are developing an Integrated Fire Control System for the Chieftain and this will include the Barr and Stroud LF-2 laser rangefinder. Some 800 of these tanks have been produced for the British Army.

The design features an exceptionally accurate and hard hitting 120 mm gun mounted on a chassis and turret affording better protection than any other in service. Nevertheless a reasonable weight has been achieved by the use of separated ammunition, employing a fully combustible bagged charge, and by lowering the turret ring through the expedient of a reclined driving position. Great care has been taken to give a good ballistic shape to the turret and hull, and the absence of a gun mantlet undoubtedly also improves the protection of the turret. It is believed that the armour thickness over the frontal arc is about 150 mm at a sloping angle of 60°, which is far superior to that of any other Western tank. The gun is fully stabilised in elevation and azimuth to permit accurate firing on the move.

The Barr & Stroud laser range finder type LF2 for the Chieftain tank. Ranges can be taken from 500 to 10,000 metres with + 10 metre accuracy for more than 90% of shots

CHARACTERISTICS:
(Mk. 5 except where stated)
Crew: 4 (commander, loader, gunner, driver)
Weight: 52.3 tons (laden) (Mk. 3) 53.8 t (Mk. 5)
Size: Height 2.75 m. Length (hull) 7.6 m. Width 3.5 m
Road speed: 40 km/h (Mk 3) 48 km/h (Mk 5)
Road range: 500 km
Main armament: 120 mm BL high velocity gun L11A2 (**2453.103**)
Method of ranging: Laser rangefinder
Rounds carried: 53 mixed HESH, APDS and smoke
Max useful range of main armament: 3,000 m APDS. 8,000 m HESH
Turret rotation: 360 degrees in 18 secs
Secondary armament: One coaxial 7.62 mm Browning MG and one 7.62 mm Browning MG mounted on commander's cupola for AA defence. One 12.7 mm ranging MG
Main engine: Leyland L60 No. 4 Mk. 7A 6 cylinder vertically opposed piston, turbocharged, multifuel 2 stroke, compression ignition. 840 bhp at 2,100 rpm. (Mk3 had 650 bhp engines)
Auxiliary engine: H30 3 cylinder, 1 litre developing 3.5 kW
Transmission: TN 12 gearbox with a Wilson epicyclic gear train and a Merritt Brown differential steering system. Electro-hydraulic gear selection
Agility: Ground pressure 0.92 kg/sq cm. Maximum step 0.9 m. Maximum trench 3.1 m. Maximum gradient 35 deg. Ground clearance 0.5 m. Power-to-weight ratio 15 bhp per ton
NBC protection: Pressurised air conditioning and filtration system
Night vision equipment: 2 kW convertible white – IR searchlight. IR filtered headlamps. IR sights for commander and gunner. IR viewer for driver. IR warning device
Additional equipment:
Snorkelling equipment for wading up to 5 m depth.
A dozer blade can be fitted to any tank.
Derivatives:
Armoured Recovery Vehicle FV 4204. This is scheduled to enter service in 1974/5 and is based on a Mk. 3 Chieftain hull. It is fitted with two winches each of the double capstan type, to give sustained pulls to the front of the vehicle of 30 tonnes and 3 tonnes respectively. An hydraulically-operated earth anchor blade is mounted on the front of the vehicle: this can also be used for simple dozing and enables the vehicle to exert a pull of 90 tonnes. The vehicle is armed with a 7.62 mm machine gun and smoke dischargers: other equipment fitted includes crew heater units and a NBC system. Basic data: – length 8,256 m, width 3,518 m (over blade), height 2.746 m, laden weight 52 tonnes, road speed 41.5 km/hr, range road 322 km and power-to-weight ratio 14.1 bhp/ton.



Chieftain Bridgelayer in operation
(Christopher F. Foss)

Chieftain Main Battle Tank with 120 mm gun. The thermal jacket on the gun prevents differential heating or cooling on opposite sides of the barrel, from affecting the accuracy of the gun

Armoured Vehicle Launched Bridge FV 4205. This is now in service with the British Army and on order for Iran. It has a crew of three men. The bridge is launched hydraulically without exposing the crew. The bridge normally carried is the No. 8 Tank Bridge, this is a class 60 scissors type 24.4 m long with a maximum span of 22.9 m; under development is the Tank Bridge No. 9 which is 13.4 m long. Basic data of the FV 4205 complete with bridge, length 13.73 m, width 4.16 m, height 3.92 m, weight 53 tonnes.

STATUS:

Chieftain MBT production has been completed for the British Army and is continuing for the Iranian Army. Chieftain ARV and AVLBs are in production for both the British and Iranian Armies.

MANUFACTURER:

Two production lines are in existence, one at Vickers Ltd, Armament Division, Elswick Works, Newcastle upon Tyne NE99 1CP, the other at Royal Ordnance Factory, Leeds.

Enquiries should be addressed to:

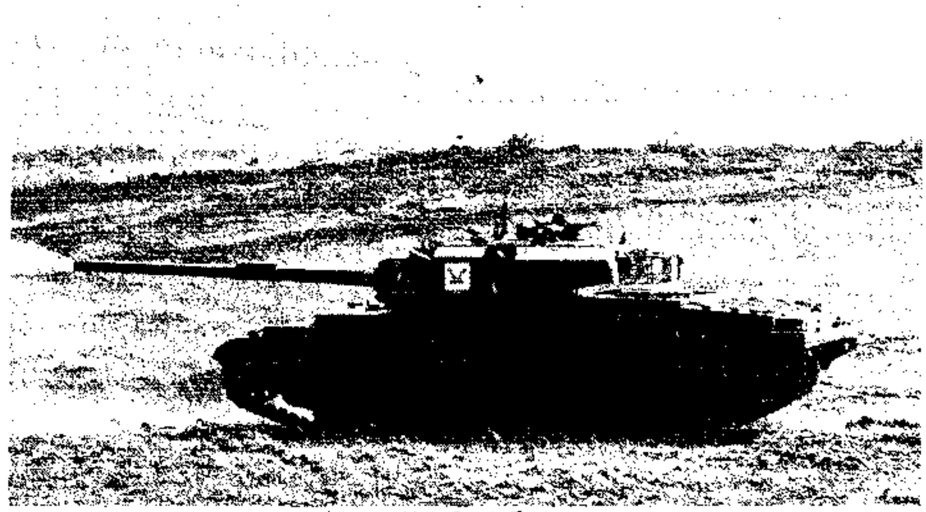
Ministry of Defence, Military Adviser (Overseas Equipment), St. Christopher House, Southwark Street, London SE1, England.

5057.102 VICKERS MAIN BATTLE TANK

DESCRIPTION:

The Vickers Main Battle Tank (Mark 1) was developed between 1958 and 1963 by Vickers Armament Division to meet the requirements of those countries needing a cheaper and lighter tank than Chieftain. The armament is that of the later marks of Centurion (105 mm gun), but with an improved transistorised gun control equipment. Engine and transmission are the same as in Chieftain. Weight was kept to 36.9 t by modifying the armour protection compared with Chieftain. Consequently this tank has the high power to weight ratio of 16.3 bhp/t, giving it a speed and cross-country mobility comparable with other battle tanks of this weight. Particular emphasis in the design has been placed on using components already proven in service and also on simplicity of training and servicing.

It is therefore particularly well adapted to the needs of countries that wish to build up an armoured force. A quantity were sold to India in 1966 and based on this initial order the Indian Government established a factory in Avadi, Madras, to manufacture tanks identical to the Vickers production under licence. In 1968 a quantity (believed to be 50) were sold to Kuwait and delivery was completed in early 1972.



Vickers Main Battle Tank

Vickers Main Battle tank Mark 3

The Mark 3 version has increased performance resulting from an increase in power and new final drive ratio giving greater acceleration and maximum speed. The turret has been completely redesigned, having a cast armour front welded to armour plate. The new design gives an improved ballistic shape, also greater crew comfort. A new cupola is fitted which gives improved vision using 'Chieftain' type sight and episcopes. The quantity of main ammunition carried has been increased to 50.

CHARACTERISTICS

The details below apply to Mark 3. The details for Mark 1 where they differ are in parentheses.

Crew: 4 (commander, gunner, loader, driver)

Weight: 38.1 (36.9) tons (laden)

Size: Height 2.48 m (2.44 m). Length 7.56 m. Width 3.16 m

Road Speed/Range: 53 (48) km/h/480 km

Main armament: British QF 105 mm high velocity gun (**2452.103**)

Method of ranging: Coaxial .50 ranging machine gun

Rounds carried: 50 (44) mixed APDS, HESH or Smoke

Max useful range of main ammunition: 1,800 m APDS, 5,500 m HESH

Turret rotation: 360° in 13 sec

Secondary armament: One coaxial 7.62 mm GPMG and provision for a second 7.62 mm GPMG on the commander's cupola

Main engine: Leyland L60 six-cylinder opposed piston, two stroke multi-fuel, compression ignition, 700 (600) bhp at 2,670 rpm. A power-pack based on the General Motors 12V-71T diesel engine is available as an alternative.

Transmission: TN12 gearbox with a Wilson epicyclic gear train and a Merritt Brown differential steering system. Electro-hydraulic gear selection

Agility: Ground pressure 0.79 (0.82) kg/sq cm. Max step 0.9 m. Max trench 2.5 m. Max gradient 30°. Ground clearance 0.4 m. Power-to-weight ratio 19.2 (16.3) bhp/ton

Water crossing ability: Unprepared wading to 1.1 m. Deep wading with preparation to 2.23 m. Optional screen can be fitted to provide amphibious capability with speed of 6.4 km/h. Erection time 15 minutes

Additional Equipment:

1. Auxiliary Engine – H30 3 cylinder 1 litre, developing 3.5 kW. (This is not required with the alternative main engine since this includes an additional alternator)
2. Night Vision Equipment – a white light/IR searchlight can be fitted to the mantlet. IR viewers are fitted to driver's and gunner's position.
3. NBC protection – pressurised air conditioning and filtration system.
4. Vehicle Heater – a heater can be incorporated in the ventilation system.

Derivatives: A recovery vehicle and bridgelayer based on the Mark 1 chassis can be offered.

MANUFACTURER:

Vickers Ltd, Armament Division, Elswick Works, Newcastle-upon-Tyne NE99 1CP, England

5040.102 SCORPION LIGHT TANK

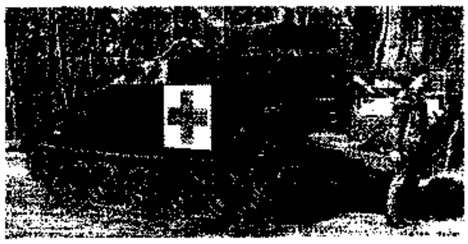
DESCRIPTION.

Scorpion is one of a range of Combat Vehicle designs specified by the British Army for world-wide deployment in the 1970s. It is intended to provide the armoured reconnaissance element in the British Army of the Rhine, whilst also employed in other parts of the world where ground conditions favour tracks as opposed to wheels for armoured support, patrol and escort duties. It has a hard-hitting gun, adequate protection and exceptional mobility.

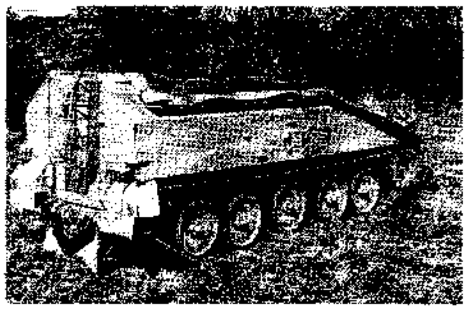
Its light weight, especially its exceptionally low ground pressure, combined with a power to weight ratio of over 26 bhp/t give it a performance in mud and bog which is not surpassed by any other light tank.

It has an inbuilt flotation screen for water crossing. Particular attention has been given to reducing the external noise for reconnaissance purposes. It has been designed from the outset for ease of maintenance and simplicity of crew duties, and should prove to be a consistently reliable vehicle. Scorpion is now in production and several thousand are on order for the British and Belgian

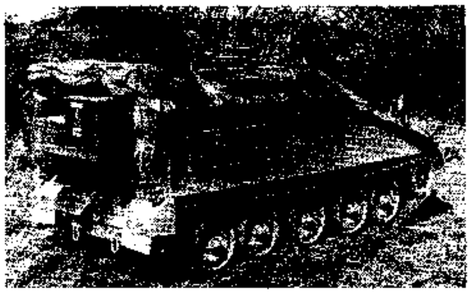
Scorpion in desert livery



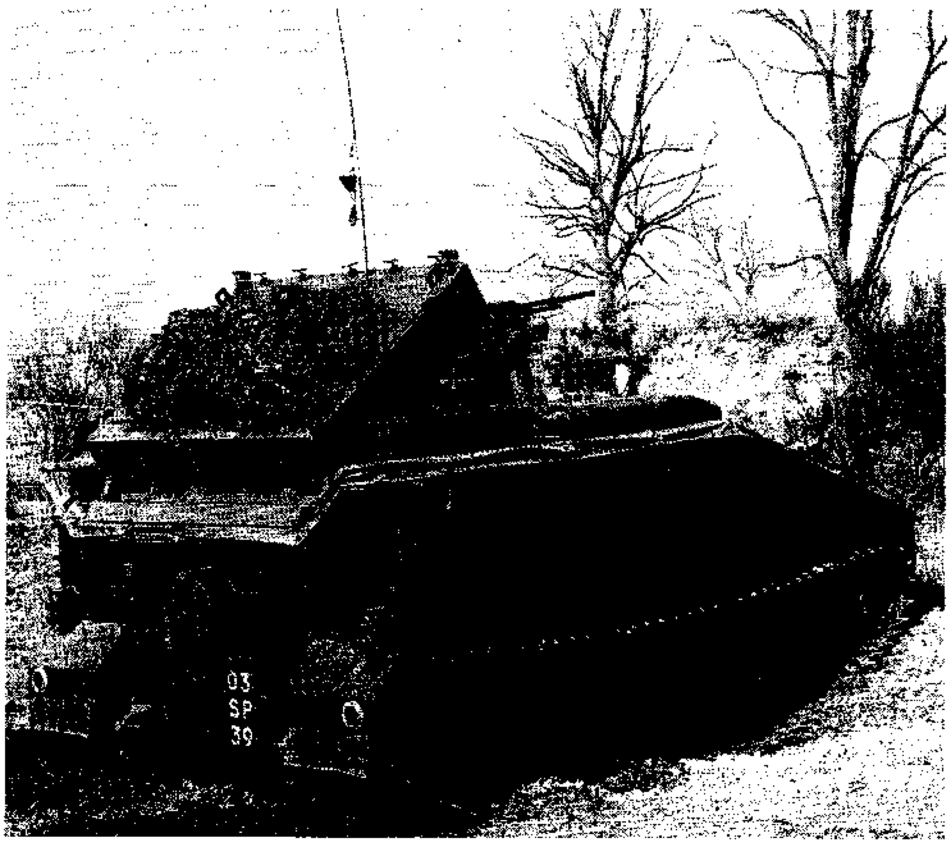
CVR(T) Ambulance : Samaritan



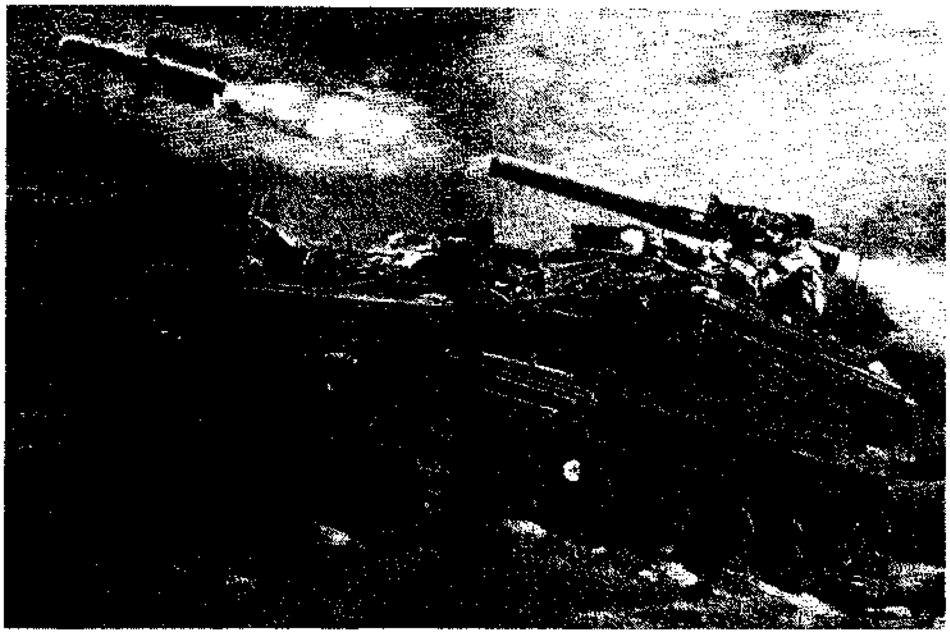
CVR(T) Recovery : Samson



CVR(T) Command : Sultan



CVR(T) GW : Striker missile launcher



Artist's impression of TOW ATGW system installed on Spartan

armed forces and for other customers overseas.

CHARACTERISTICS:

Crew: 3 (commander, gunner, driver)

Weight: 7.8 tonnes

Size: Height 2.1 m. Length (gun forward) 4.3 m. Width 2.18 m

Road Speed / Range: 87 km / h / 640 km

Main armament: 76 mm gun

Method of ranging: Commander's estimation or use of coaxial MG as ranging gun

Rounds carried: 40. Mixed HESH (armour defeating) high explosive

Maximum range of main armament: 5,000 m

Secondary armament: Coaxial 7.62 mm MG, which can be used as ranging gun

Turret rotation: 360°, by two-speed hand traverse mechanism

Armour type: Welded aluminium plate

Engine: Jaguar XK 6-cylinder petrol engine 4,200 cc 195 bhp at 5,000 rpm. The engine compartment is at the front, alongside the driver

Transmission: Semi-automatic, electrically actuated combined gearbox and steering unit, similar in design to that on Chieftain. Transmission compartment at front of vehicle, with drive to front sprockets.

Agility: Ground pressure 0.35 kg/sq cm. Max step 0.5 m. Max trench 2.06 m. Max gradient 60% (31°). Ground clearance 0.35 m. Power-to-weight ratio 26.3 bhp / tonne

Water crossing ability: Fording without preparation to 1.07 m. Inbuilt flotation screen can be speedily erected by the crew, to give swimming capability in inland waters, propulsion by tracks at 7.0 kph

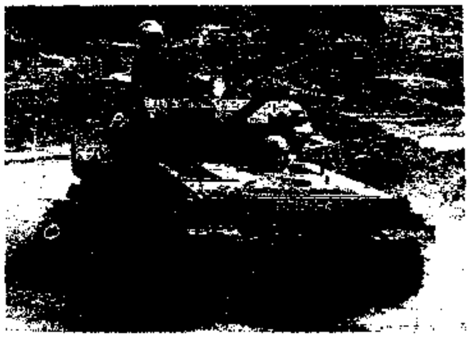
NBC protection: Vehicle can be pressurised, with a filter in the air intake. Detectors to indicate NBC attack can be fitted

Night vision aids: Passive sights for commander and gunner, and driver's viewer will be fitted as extra equipment on British and Belgian Army vehicles.

Variants: The following variants in the CVR series have been developed:

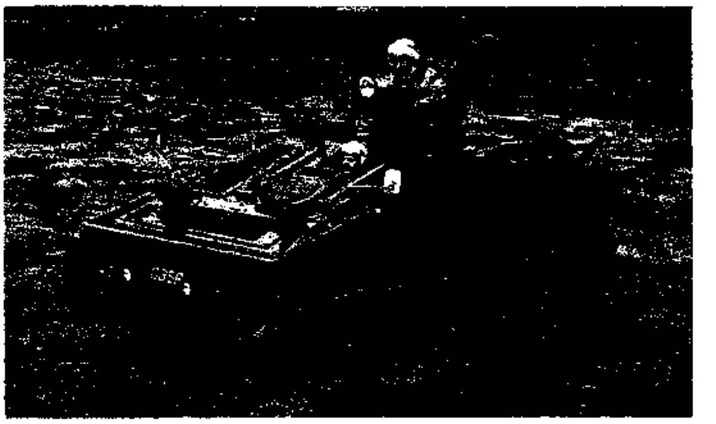
CVR(T) GW	Striker – 5 Swingfire launchers
CVR(T) 30	Scimitar – Rarden 30 mm cannon
CVR(T) APC	Spartan – APC
CVR(T) Command	Sultan – Command vehicle
CVR(T) Ambulance	Samaritan – Ambulance vehicle
CVR(T) Recovery	Samson – Recovery vehicle

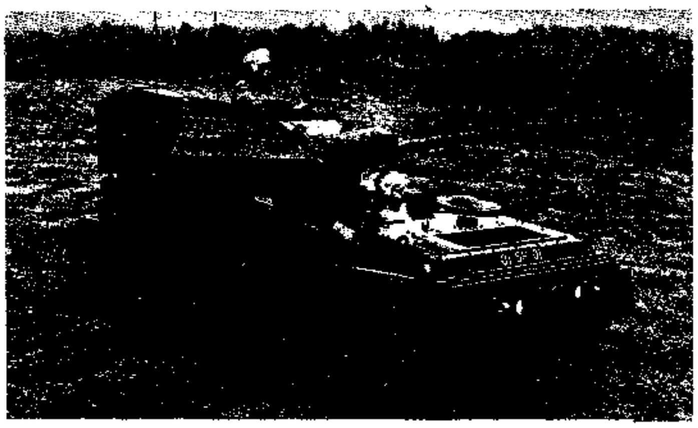
Pictures of these variants are shown here. Striker, the missile launcher, was first publicly exhibited at the 1972 Farnborough Air Show. The



CVR(T) FS Scorpion

Swingfire missiles are carried in their protective launchers at the rear of the vehicle and are elevated for firing by an hydraulic ram. Spare missiles





Scimitar (left) uses the basic Scorpion hull and a turret modified to take the 30 mm Rarden cannon Spartan is an APC and can accommodate an assault section consisting of a commander and four men in addition to the driver and gunner. Periscopes, episcopes, a night sight and a spotlight are provided and the vehicle can carry Radar No. 14 on the roof

are carried under armour in the hull of the vehicle.

Scimitar uses the basic Scorpion hull and turret with the modifications necessary to incorporate the Rarden 30 mm cannon (**5504.103**) in place of the 76 mm gun.

As can be seen, Spartan has a box hull and this is designed to accommodate an assault section consisting of a commander and four men in addition to the driver and gunner. Periscopes, episcopes and a spotlight are provided; and the vehicle can also carry Radar No. 14 (**2490.153**) on the roof.

STATUS:

The Scorpion family is in production in the United Kingdom and Belgium. It is in service with Abu Dhabi, Belgium and United Kingdom. It is also reported that Canada and Iran have placed orders for members of the family.

MANUFACTURER:

Alvis-British Leyland UK Ltd., Holyhead Road, Coventry, England. Enquiries to Director of Sales (Army), Ministry of Defence, St. Christopher House, Southwark Street, London S.E.1., or to Sales Manager, Military Sales Dept, British Leyland Motor Corporation Ltd, 41-46 Piccadilly, London W1V 0BD, England.

5064.102
FOX ARMOURED CAR

DESCRIPTION:

The Fox is a logical development of the Ferret scout car (**5002.102**). Design started in 1965/66 and the first prototypes were completed by Daimler in 1967. After various trials and modifications a production order was awarded to the Royal Ordnance Factory at Leeds. The first production Fox was completed early in 1973 but by early 1974 the vehicle was still not in service.

The hull and turret of the Fox are constructed of light alloy armour to save weight: the vehicle is, however, some 2 tons heavier than the Ferret Mk. 2/3. It is powered by the same engine that is fitted to the Scorpion CVR(T) which gives a power-to-weight ratio of 32 bhp/ton and gives the vehicle an exceptional road and cross-country performance. The 30 mm Rarden cannon can fire all Hispano 831 L 30 mm ammunition as well as the specially developed British APDS round. The APDS round will kill any light AFV at ranges of at least 1,000 m, and also damage the sides of MBT. The spent cartridge cases are ejected outside the fighting compartment.

The Fox Armoured Car, travelling at speed

The design shows many unusual and interesting features. It would however, seem unlikely that the Fox will be anything like as successful as the Ferret. This does not imply that Fox is not a good vehicle, just that it has arrived a few years too late for, at any rate large, export orders.

CHARACTERISTICS:

Crew: 3 (commander/loader, gunner, driver)
Weight: 6.386 tonnes (loaded)
Size: Length 4.24 m (hull). Width 2.134 m. Height 2.2 m (overall)
Road Speed/Range: 104 km/hr/434 km
Main armament: Rarden 30 mm cannon with single shot or bursts (up to 6 rounds) capability (**5504.103**)
Method of ranging: Gunner has one periscope binocular x1 and x10 sight linked to main armament
Rounds carried: 96 rounds of 30 mm in clips of three. Uses Hispano 831 L ammunition plus an APDS round specially developed for this gun
Elevation: From +41° to −14°, permitting the engagement of light aircraft and helicopters
Turret rotation: 360°, power assisted hand traverse
Secondary armament: 7.62 mm co-axial MG, 2,600 rounds of MG ammunition carried
Engine: Jaguar XK 4.2 litres, 6 cylinder, petrol developing 185 bhp at 4,750 rpm
Transmission: Fluid flywheel and pre-selector 5 speed gearbox. Transfer box selects forward or reverse
Agility: Ground pressure 0.46 kg/cm^2. Max trench (with channels) 1.22 m. Ground clearance 0.3 m. Power-to-weight ratio 32 bhp/ton
Water crossing ability: Flotation screen permanently fitted can be erected in 1½ minutes. Water propulsion and steering by wheel spin at speed of 5 km/hr. Wading to a depth of 1.01 m without preparation
Night vision equipment: Gunner has passive night sight (optional) and driver has passive night periscope (optional)
Sensory equipment: As a reconnaissance vehicle Fox has been designed to carry a full complement of sensory and surveillance devices including the ZB298 (Type 14) battlefield radar (**2490.153**), IR and NBC detectors
Variants: The Vixen (FV 722) Combat Vehicle Reconnaissance (Wheeled) Liaison is being developed by MVEE. It will have a Fox type hull but be fitted with a simple turret mounting a single 7.62 mm MG, and will be able to carry four men. It is possible that the Fox turret may be retrospectively fitted to some FV 432s used by infantry battalions. Some work has also been carried out for fitting the Fox turret to the M-113.

MANUFACTURER:

Saladin was made by Alvis Ltd, Holyhead Road, Coventry, England but is no longer in production. rently in production at the Royal Ordnance Factory, Leeds, England.

5005.102
SALADIN ARMOURED CAR

DESCRIPTION:

Saladin was developed in parallel with the Saracen Armoured Personnel Carrier (**5001.102**), with which it shares many component parts. It entered service with British Reconnaissance Regiments in 1955, and has seen active service in a wide variety of internal security situations such as Malaya, Borneo, Aden, Kenya and Cyprus. It has also been in service with the armies of: Australia, Abu Dhabi, Bahrain, Germany (FRG), Ghana, Indonesia, Jordan, Kenya, Kuwait, Libya, Muscat, Nigeria, Quatar, Sudan, Tunisia and is still in widespread use. It has an accurate and hard hitting gun, and excellent cross-country mobility over countryside that favours wheels. It has proved to be well equipped to withstand mine damage, which is the principal source of danger to armoured vehicles in an internal security situation. On several occasions Saladins have been able to motor away from a mine incident with two wheel stations destroyed. Saladin probably represents the best combination of mobility, fire-power and protection available in any armoured reconnaissance vehicle currently in service. It has proved to be adaptable to a very wide range of climatic conditions, and to be well suited to transportation by air, by landing craft or by assault boat.

CHARACTERISTICS:

Crew: 3 (commander/loader, gunner, driver)
Weight: 11.6 t (laden)
Road Speed / Range: 72 km/h/160 km
Armament: 76 mm gun with 7.62 mm MG coaxially mounted and another 7.62 mm MG for the commander pintle-mounted on the roof
Method of ranging: Commander's estimate
Rounds carried: 42, mixed HESH, HE and smoke

STATUS:

The Saladin armoured car is used by Abu Dhabi, Bahrain, Great Britain, German Border Police, Ghana, Indonesia, Jordan, Kuwait, Libya, Muscat and Oman, Nigeria, Portugal, Qatar, South Yemen, Sudan, Tunisia and Uganda.

Saladin Armoured Car

MANUFACTURER:

Saladin was made by Alvis Ltd, Holyhead Road Coventry, England but is no longer in production.

5007.102
FV 432 ARMOURED PERSONNEL CARRIER

DESCRIPTION:

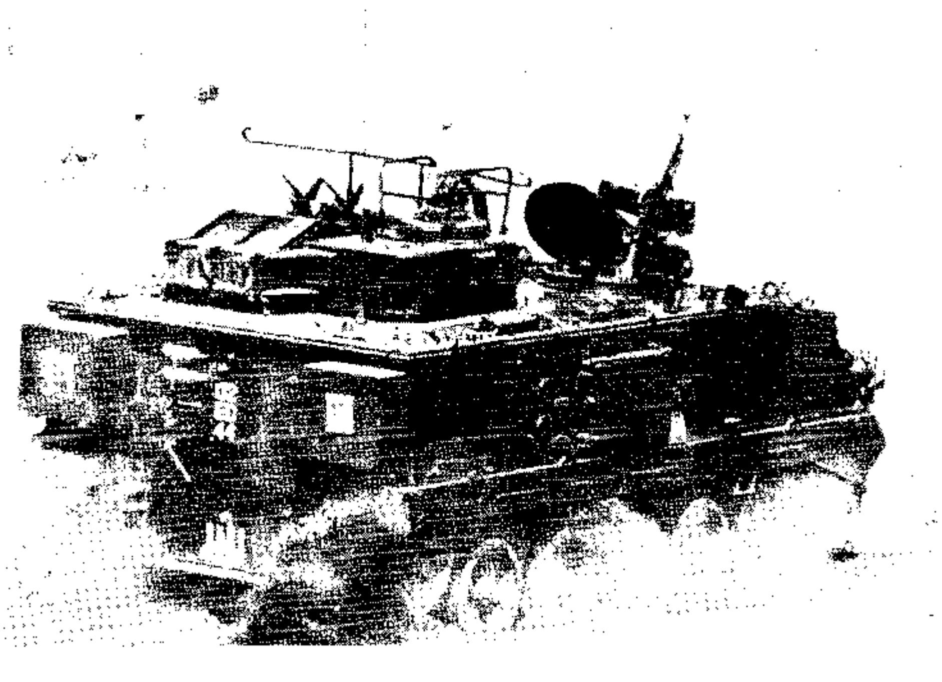
The FV 432 was developed between 1955 and 1961 to provide a high-mobility Armoured Personnel Carrier for the British Army in Germany. An order for about 1 000 vehicles was placed in 1961, and has now been delivered. FV 432 has been the standard APC with British mechanised infantry battalions since 1964.

The FV 430 series of vehicles was originally intended to provide the British Army with a range of armoured tracked vehicles for combat use, in the roles of artillery gun, APC, supply vehicle, recovery vehicle, ambulance and so on, all based on the same chassis. The scheme is now complete; and although various necessary compromises have resulted in some departures from the original plan the entry into service of FV 432 and its many derivatives has given the British Army a range of fast, reliable and versatile tracked vehicles.

CHARACTERISTICS:

Crew: 2 (commander, driver) plus a section of 10 men. The driver is situated right front, the commander central, with the engine at left front
Weight: 15.1 t
Size: Height (to roof) 1.88 m. Length 5.10 m. Width 2.97 m
Road speed / range: 52 km/hr/580 km
Armament: 7.62 GPMG, pintle-mounted on the roof, 2 000 rounds carried
Engine: Rolls-Royce K60 6 cylinder multi-fuel compression ignition opposed piston 2 stroke 240 bhp at 3,750 rpm
Transmission: Allison TX 200 4A heavy duty automatic gearbox, giving six forward and one reverse gears
Exit for Section: Single door at rear of vehicle swinging open on vertical hinges on right side of vehicle
Agility: Ground pressure 0.78 kg/cm. Maximum gradient 35°. Maximum step 0.6 m. Maximum trench 1.82 m. Ground clearance 0.4 m. Power-to-weight ratio 16 bhp/ton
Water crossing ability: Fording without preparation to 1.1 m. Collapsible screen available which can be erected in 1 minute, to provide amphibious capability.
Night vision equipment: Driver's IR viewers, combined with IR headlamp filters vehicle to be driven at night

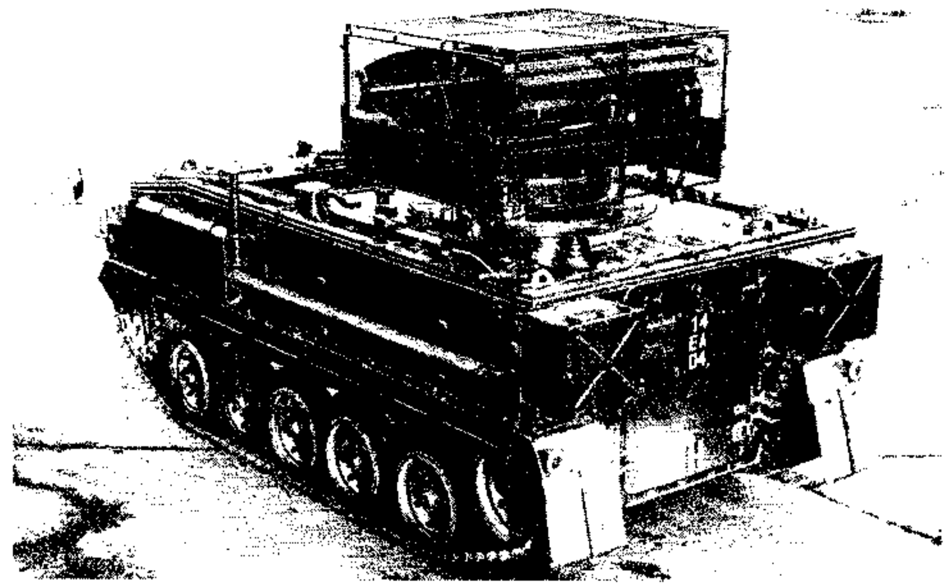
FV432 with Wombat recoilless anti-tank gun



FV438 Swingfire launch vehicle (Christopher F. Foss)

Derivatives:
The basic FV 432 chassis can be and has been, readily adapted to many roles. These include:
a. carriage for Wombat anti-tank gun and crew (**2476.103**)
b. command post
c. cargo vehicle, particularly for ammunition and fuel
d. carriage for 81 mm mortar and crew
e. ambulance (4 stretchers, or 2 stretchers with 5 sitting)
f. recovery vehicle (8 ton winch)
g. artillery observation post
h. carriage for Cymbeline Mortar locator radar (**1018.153**)
i. FACE vehicle (**2415.163**)
j. minelaying vehicle
k. navigation vehicle
l. Carl Gustav (**5557.103**) carrier
m. battlefield radar (No 14 – **2490.153**)
n. with Rarden turret (**5504.103**)
o. with GPMG turret

Other vehicles on the same chassis type include:
Abbot self-propelled gun (**5503.103**)
FV 434 recovery vehicle
FV 436 with the Green Archer mortar locating radar (**2412.151**)
FV 438 with Swingfire missiles (**2450.111**)



Rear view of FV432 with Cymbeline mortar locator mounted on it (reflector folded for transit)

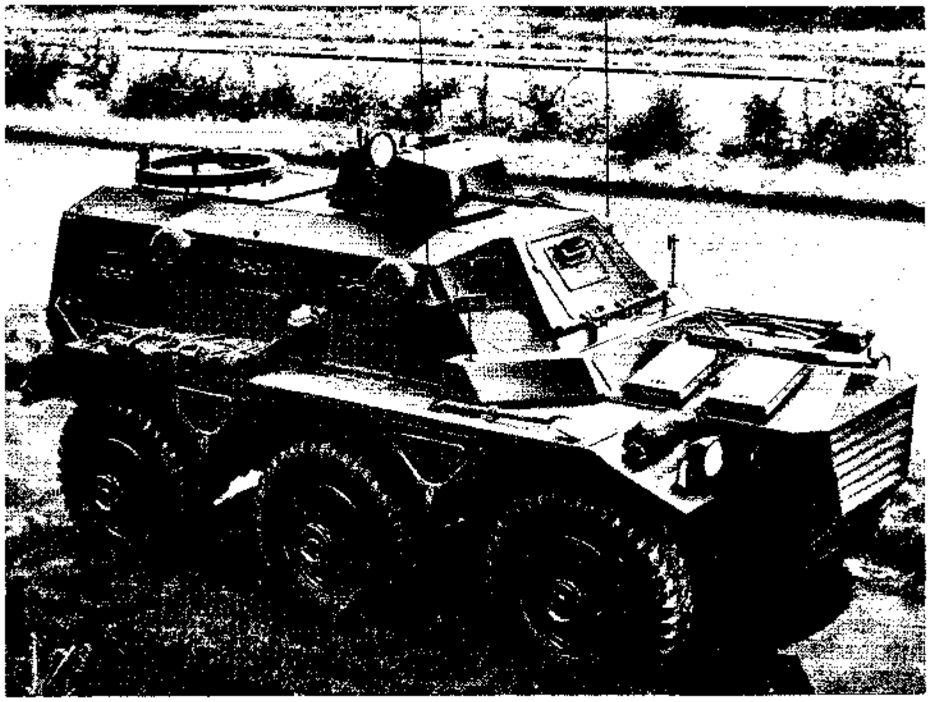
MANUFACTURER:
Joseph Sankey and Sons Ltd, Hadley Castle Works, Wellington, Shropshire, England.

5001.102
SARACEN ARMOURED PERSONNEL CARRIER

DESCRIPTION:
Developed between 1950 and 1953, Saracen was rushed into service to meet the requirements of the Malayan emergency. Since then it has more than proved its value as a versatile reliable and speedy personnel carrier. It has a remarkable cross-country performance, especially in dry, hard conditions, and can negotiate narrow, winding tracks through jungle or mountain with ease, achieved largely by its four wheeled, hydraulically assisted steering. Its road speed and silence makes it particularly valuable in internal security operations, and it has seen service in this role in such places as Malaya, Borneo, Kenya, Cyprus and Aden.

It has been in service with British mechanised infantry battalions and reconnaissance regiments and with the armed forces of Abu Dhabi, Australia, Brunei, Hong Kong, Indonesia, Jordan, Kuwait, Libya, Nigeria and Qatar. It is still in widespread use.

CHARACTERISTICS:
Crew: 2 (commander and driver) plus infantry section of 10 men
Weight: 10.4 tonnes (laden)
Road speed: 72 km/h
Armament: 0.30 Browning Machine gun in one-man turret
Rounds carried: 3,000 MG
Derivatives: In addition to the Saladin Armoured car (**5005.102**), built on essentially the same chassis, the following adaptions of Saracens have been produced:
Armoured Ambulance – 4 stretcher cases
Command vehicle – specially heightened body, and penthouse canvas shelters at back and sides. Map boards, racking and additional battery charging facilities
Specialist Cargo Vehicle – for engineer stores
Radar Vehicle – mounted radar No. 9 (Robert) long range ground surveillance radar.
For hot climates there was also a derivative using reverse flow cooling



Saracen Armoured Personnel Carrier

STATUS:
Saracens are still used by Abu Dhabi, Brunei, Great Britain, Hong Kong (Police), Indonesia, Jordan, Kuwait, Libya, Nigeria, Qatar, South Africa, Sudan, Thailand and Uganda.

MANUFACTURER:
Manufactured by Alvis Ltd, Holyhead Road, Coventry, England but no longer in production.

5002.102
FERRET SCOUT CAR Mks 1 & 2

DESCRIPTION:
The Ferret was developed between 1951 and 1953 from the famous Daimler Scout Car which had been in service since 1940. It has since been produced in very large numbers both for the British Army and the following foreign armies and police forces: Abu Dhabi, Australia, Bahrain, Brunei, Canada, Ceylon, Congo, France, Gambia, Ghana, India, Indonesia, Iran, Iraq, Jamaica, Jordan, Kenya, Kuwait, Libya, Malaysia, Muscat, Netherlands, New Zealand, Nigeria, Qatar, Ras al Khaima, Rhodesia, Singapore, Somalia, South Africa, South Arabia, Sudan, Uganda, United Nations and Zambia. It has seen service as a reconnaissance, liaison, escort and patrol vehicle in a wide variety of internal security and 'small war' situations in every sort of climate, and every sort of country. It has proved time and again that its reliability, mobility and ease of maintenance are well matched to its roles and to the standard of training of those who use it. It has been one of the most successful and best liked armoured vehicles developed since 1945, and has many more years of useful service ahead of it. The Mark 1 version has no turret, but can carry a machine gun on a pintle mounting for use by the commander. It can also carry a third person as passenger. The Mark 2 version has a one-man turret which can be traversed through 360° by the shoulder and arm movements of the commander, and which mounts a 7.62 mm MG.

CHARACTERISTICS:
Crew: 2 (commander, driver)
Weight: Mk. 1 – 4,218 kg (laden); Mk. 2 – 4,400

kg (laden)
Size: Height – Mk. 1 – 1.45 m; Mk. 2 – 1.87 m. Length 3.8 m. Width 1.9 m
Road speed / range: 93 km / h / 305 km
Armament: Mk. 1 – 0.30 Browning or .303 Bren on pintle mounting; Mk. 2 – .30 Browning in turret
Rounds carried: Mk. 1 – 450 rds; Mk. 2 – 2,500 rds
Turret rotation: Mk. 2 – 360 degrees, but restricted by Commander sitting on fixed seat whilst traversing with his shoulders and arms
Engine: Rolls-Royce B60, petrol, spark ignition, six cylinder, 6.4 to 1 compression ratio, 120 bhp at 3,300 rpm
Trans-: Daimler fluid coupling with 5 speed epicyclic gearbox and transfer box to give 5 forward and 5 reverse speeds
Agility: Max step 0.4 m. Max trench 1.2 m (with channels). Ground clearance 0.33 m. Max gradient 24 degrees. Shallow fording up to 0.9 m. Deep fording up to 1.5 m with preparation. Power-to-weight ratio 27 bhp / ton
Additional equipment: Infra-red headlamp filters used in association with driver's IR binoculars. Deep fording screen. Applique kit to mount 2 Vigilant anti-tank missiles ready-to-fire, plus 2 missiles stowed, on existing Mk. 2 or Mk. 1 vehicles

STATUS:
The Ferret is in service with Abu Dhabi, Bahrain, Brunei, Burma, Cameroons, Canada, Ceylon, Gambia, Ghana, Great Britain, Iran, Indonesia, Iraq, Jamaica, Jordan, Kenya, Kuwait, Libya, Malaysia, Mali, Muscat & Oman, New Zealand, Nigeria, Qatar, Ras Al Khaimah, Rhodesia, Sierra Leone, Somali, South Africa, South Arabia, South Yemen, Sudan, Uganda, Zaire and Zambia.

MANUFACTURER:
Manufactured by the Daimler Company Ltd, Radford, Coventry, England. Production ceased in August 1972 by which time some 4,400 Mk 1, Mk 2 and Mk 5 (**5065.102**) vehicles had been produced.

Vigilant missile launched from Ferret scout car

Ferret Mk 1 (Christopher F. Foss)

Ferret Mk 2 (Christopher F. Foss)

5065.102
FERRET Mk 5 MISSILE LAUNCH VEHICLE

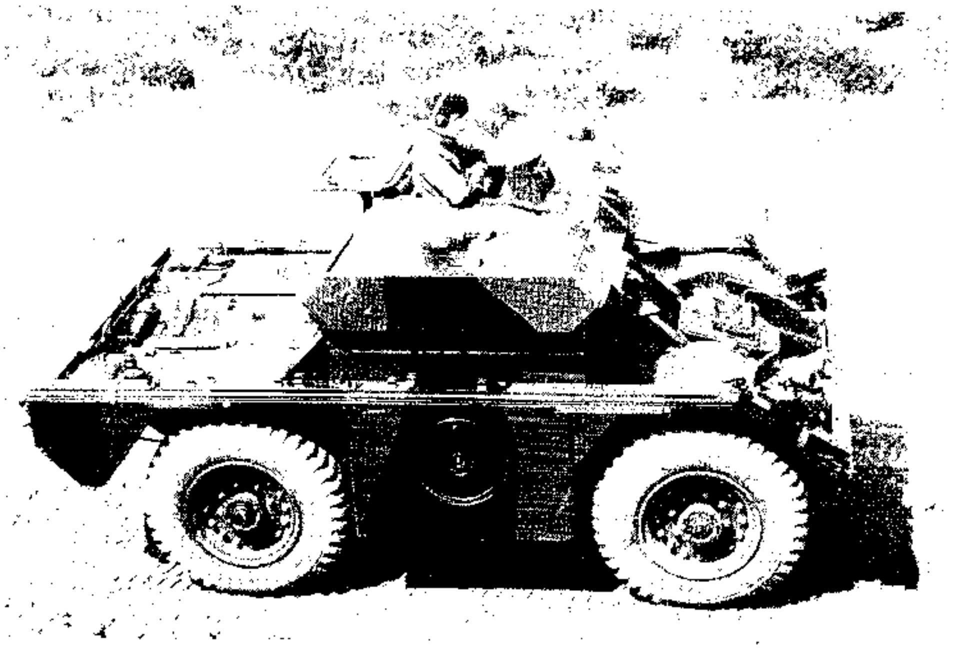
DESCRIPTION:

The Mk 5 Ferret is a logical development from the well-proven Mks 1 and 2. It is fitted with a special fully-rotating turret carrying four BAC Swingfire missiles giving an anti-tank range out to 3,000 m. The missiles can be fired either from the vehicle or remotely by a separation sight which can be carried to a position where the missile controller can observe the approach of targets, whilst the launch vehicle remains hidden. This system overcomes one of the main objections to the use of anti-tank missiles, which is the length of time the launch vehicle must remain exposed to attack during the time of flight of the missile. It also removes the need to provide a heavily protected launch vehicle.

The Mk 5 Ferret is wider, and heavier than Mks 1 and 2, and has a flotation screen permanently attached. The suspension system has been strengthened to allow a considerable improvement in cross-country performance, especially over rough ground. The special turret is fabricated of aluminium armour to keep the combat weight down to 5.89 t. At this weight the Mk 5 Ferret can be readily air-transported and parachute-dropped. It therefore offers a means of providing long-range anti-armour defence in air transported and amphibious operations. It also enables any army to provide itself with an effective long range anti-armour defence system at far less cost and complexity than by the use of tanks.

CHARACTERISTICS

Crew: 2 (driver and commander/controller)
Weight: 5.89 t
Size: Height 2.0 m. Length 4.1 m. Width 2.1 m
Road speed/range: 80 km/h/240 km
Armament: 4 Swingfire missiles housed in armoured containers forming part of a full-rotating turret. Further two Swingfire missiles carried. 7.62 mm MG mounted coaxially
Engine: Rolls-Royce B60 6 cylinder, 4.3 litre, petrol engine 6.4 to 1 compression ratio. 129 bhp at 3,750 rpm
Transmission: Daimler pre-selected epicyclic gearbox providing five speeds. Transfer box selects forward or reverse. Daimler fluid coupling
Power to weight ratio: 24 bhp/t
Water crossing ability: Unprepared wading to 1.0 m. Swims with screen erected, propulsion by wheel spin at 3.9 km/h

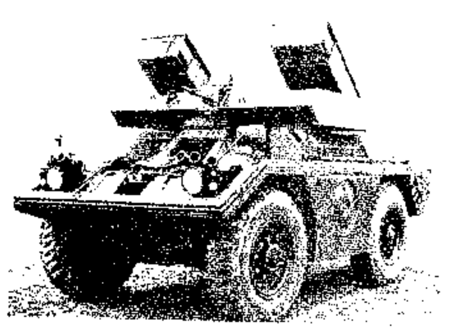


Ferret Mk 5 (Christopher F. Foss)

MANUFACTURER.

Vehicle: The Daimler Company Limited, Radford, Coventry, England.
Missile system British Aircraft Corporation, Guided Weapons Division, Stevenage, Hertfordshire, England

Production of Ferret Mk 1, Mk 2 (**5002.102**) and Mk 5 vehicles was completed in August 1972, by which time some 4,400 vehicles had been produced.



Ferret Mk 5, showing the four Swingfire missile containers in the elevated position ready for firing

5017.102
SHORLAND ARMOURED CAR

DESCRIPTION:

Developed by Short Brothers and Harland as a private venture between 1965 and 1966, this is essentially a long-wheelbase Landrover chassis clad in 8 mm armour plate, mounting a Ferret-type turret with a 7.62 millimetre machine gun. It is designed as an inexpensive, reliable and versatile internal security, patrol, escort and surveillance vehicle. With the increasing need for light armoured vehicles by armies and police forces in cities, it has been adapted to carry water cannon and tear gas equipment. It has been designed to withstand attack from small arms, 'Molotov cocktails', petrol bombs and hand thrown missiles.

Consideration has been given to the comfort and safety of the crew who may be required to remain 'closed down' for long periods, by providing heating or cooling fans, a spacious crew compartment, lined with polyurethane foam padding, and a number of quick access-safety hatches.

The Shorland can be driven by anyone who can drive a private car with no special training. Servicing and repair are both simple and cheap. It was the first vehicle designed to cope with the new sort of city warfare being experienced by armies and police forces all over the world. Fleets of these vehicles have been supplied to a large number of countries in many parts of the world. The Mk III version is detailed below. The Mk I and II have a lower powered 4-cylinder engine.

Shorland Armoured car

CHARACTERISTICS:

Crew: 3 (commander, driver, turret gunner)
Weight: 3.360 kg laden
Size: Height 2.29 m. Length 4.6 m
Road speed/range: 88 km/h/320 km (Standard tank) 640 km (long range tank)
Armament: 7.62 mm MG in turret. Stowage for 1,500 rounds
Turret rotation: 360° manually operated
Egnine: Rover petrol 2.6 litre 6 cylinder giving power/weight ratio of 27.6 bhp/ton
Transmission: Dry clutch, 2 and 4 wheel drive, manual gearbox, 4 forward, one reverse with lower ratio
Agility: Ground pressure 2.4 kg/sq cm. Max step 0.23 m. Ground clearance 0.25 m. Normal Landrover wading capability
Derivatives: If required a Vigilant ATGW in launcher box can be mounted either side of the turret. A more recent model is the SB 301 armoured personnel carrier, which does not have a turret and is designed to transport men.

STATUS:

The Shorland Armoured Patrol Car is in service with at least 16 countries.

MANUFACTURER:

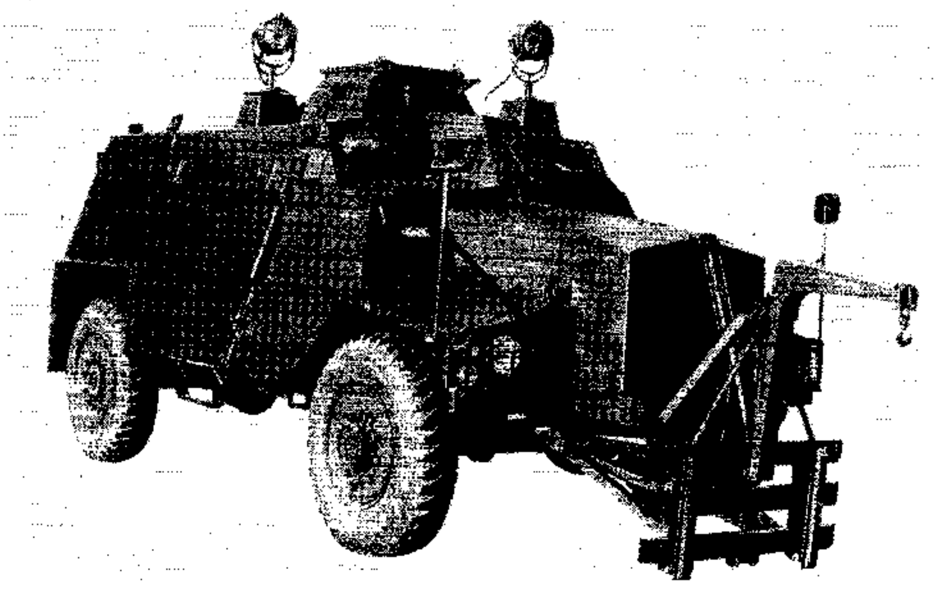
Short Brothers and Harland, Glen Works, Newtownards, Co. Down, N. Ireland

5117.102
AT 104 ARMOURED PERSONNEL CARRIER
DESCRIPTION:

The AT 104 Armoured Personnel Carrier is a 4 × 4 vehicle designed by GKN Sankey Limited specifically for internal security duties. It can transport up to 12 men and their equipment, and its hull provides protection from 5.56 mm and 7.62 mm AP rounds. For quick deployment double doors are provided at the rear and a single door in the side in addition to the driver's door. There are two gun ports in each side, a single gun port at the front and a further two gun ports in the rear of the vehicle.

In addition to being used as an APC the AT 104 can also serve as a command post or communications vehicle, ambulance, recovery vehicle, reconnaissance and airfield security vehicle. Many optional extras are available including a heating kit, air conditioning, searchlights on the roof, grenade dischargers, a turret with a 7.62 mm MG, a loudspeaker system, a barricade remover and a hydraulic winch with a maximum pull of t 5ons.

CHARACTERISTICS:
Crew: 2 plus 8 / 10 men
Weight: 8.9 t (loaded)
Size: Length 5.486 m. Width 2.438 m. Height 2.41 m
Road speed: 80 km / hr
Engine: GM Bedford 6 cylinder diesel developing 146 bhp at 2,800 rpm
Transmission: GM Allison AT.540 automatic gearbox with 4 forward and one reverse gears. GM Transfer box with two speeds



AT104 APC fitted with (detachable) barricade remover

Armament: fitted to customers requirements
STATUS:
In service with the Danish State Police.

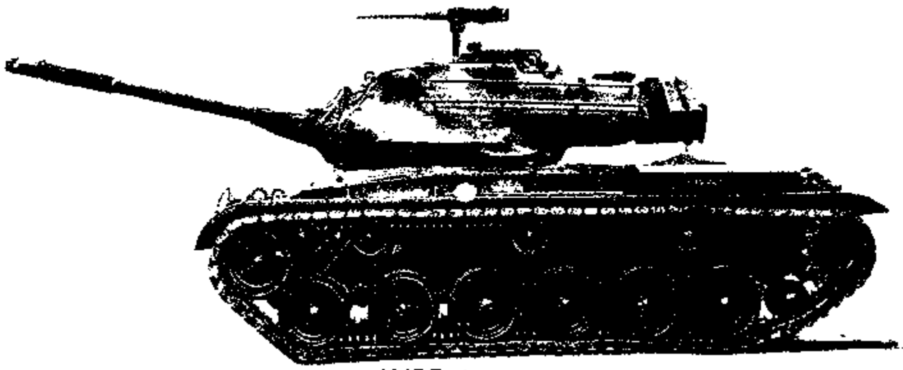
MANUFACTURER:
GKN Sankey Limited, Special Vehicle Division, Hadley Castle Works, Telford, Salop, England.

THE UNITED STATES OF AMERICA

5046.102
M47 MAIN BATTLE TANK
DESCRIPTION:

The design of the M47 originated with the Medium tank M26, which was taken into service in the US Army in 1945, as successor to the M4 (Sherman). With a better power plant, and other minor improvements M26 became M46 (Patton) in 1948. The M46 was then in turn improved to produce the M47 in 1951. The hull and suspension of the M46 were retained, but a more powerful engine was installed and a better-shaped turret was designed. It is believed that there are no longer any M46 tanks in service with any army, but M47 continues in service in many countries. Large numbers resulted from Korean War production, and these, as M48 replaced M47 in US Army service, were offered as Military Aid to Austria, Belgium, France, W. Germany, Greece, Italy, Pakistan, Persia, Spain and Yugoslavia during the middle and late 1950s. M47 is therefore one of the best-known tanks in the world, and has earned a reputation for mechanical reliability and good mobility.

CHARACTERISTICS:
Crew: 5 (commander, turret gunner, hull gunner, loader, driver)
Weight: 44 tons (laden)
Size: Height 2.96 m. Length (hull) 6.33 m. Width 3.50 m
Road speed / range: 40 km / h / 128 km
Main armament: 90 mm gun M-36
Method of ranging: Stereoscopic rangefinder
Rounds carried: 71 rounds HE and HVAP mixed
Turret rotation: 360° in 10 secs



M47 Tank

Secondary armament: One 0.3 m MG hull mounted. 0.3 in MG coaxially mounted. One 0.5 in MG pintle mounted on roof for AA defence
Engine: Continental V-12 air-cooled model AB-1790-5B. 29.4 litres. 810 bhp at 2,800 rpm
Transmission: Allison CD-850-4 cross drive system with hydraulic torque converter. Two forward speed ranges, one reverse
Agility: Ground pressure 0.94 kg/sq cm. Max step 0.91 m. Max trench 2.58 m. Max gradient 60%. Ground clearance 0.45 m. Power to weight ratio 18.5 bhp/ton
Water crossing ability: Wades to 1.22 m
Night vision equipment: Nil

Variants: Many variants have been produced either for US Army or by local manufacture in the countries to which M47s were supplied. These include:
- Recovery vehicle
- Armoured engineer vehicle
- Assault bridge

Reference may also be made to entries (**2006.102**) and (**2015.102**) for details of Italian and Austrian modifications.

STATUS:
No longer in line service with the US Army or USMC (although there may be some in reserve formations) but still in widespread service elsewhere.

5056.102
M48 MAIN BATTLE TANK
DESCRIPTION:

The M48 is a redesigned and 'stretched' version of the M47 main battle tank (**5046.102**), employing many of the M47 components. Its distinguishing features are the re-designed turret shape, with a much-reduced rear overlap, a new and rather conspicuous commander's cupola, and a transverse muzzle brake on the 90 mm gun. It was developed up to 1953, since when many thousands have been manufactured. The early marks used a petrol engine, which gave a rather poor radius of action; but from 1964 the M48 A3 was manufactured using many components of the M60 tank including the Continental V12 diesel engine which gives a greatly improved radius of action. The M48 A3 is still in service in large numbers with the US Army, and its reliability and simplicity, as demonstrated during extensive service in Vietnam, showed it to be still a very satisfactory tank. It is also used by the US Marine Corps as its main tank armament. It has been partly superseded by M60 A1 tanks in regular battalions of the US Army in USA and Germany and, beginning in FY 1974, it will progressively be replaced in USMC service by the M60 A1.

CHARACTERISTICS:
Crew: 4 (commander, gunner, loader, driver)
Weight: 47.6 tons

Size: Height 3.09 m. Length 6.87 m Width 3.63 m

Road speed/range: M48 (early marks) 48.3 km/h/160 km. M48 A3 48.3 km/h/400 km

Main armament: 90 mm. M41 gun (**2832.103**)

Method of ranging: Stereoscopic rangefinder on early marks. Replaced by coincidence rangefinder on M48 A3

Rounds carried: 60 rounds mixed HVAP, HEAT, HE, WP or canister

Turret rotation: 360°

Secondary armament: 7.62 mm MG coaxially mounted in turret. One 0.5 in Browning MG for anti-aircraft use by commander in turret-mounted cupola

Armour: Both the hull and turret are constructed of cast steel

Engine: M48 and M48 A1 powered by Continental AV-1790 SRS 12-cylinder petrol engine; 810 bhp at 2,800 rev/min. M48 A2 has AVL-1790-8 petrol engine: 825 hp at 2,800 rev/min. M48 A3 has Continental AVOS-1790-2A diesel: 750 hp at 2,400 rev/min

Transmission: Allison cross-drive hydraulic

Agility: Ground pressure 0.84 kg/sq cm. Max step 0.91 m. Max trench 2.59 m. Max gradient 60%. Ground clearance 0.39 m. Power-to-weight ratio 17 bhp/ton (M48 A3. 18.5 bhp/ton)

Water crossing ability: Wading without preparation to 1.2 m

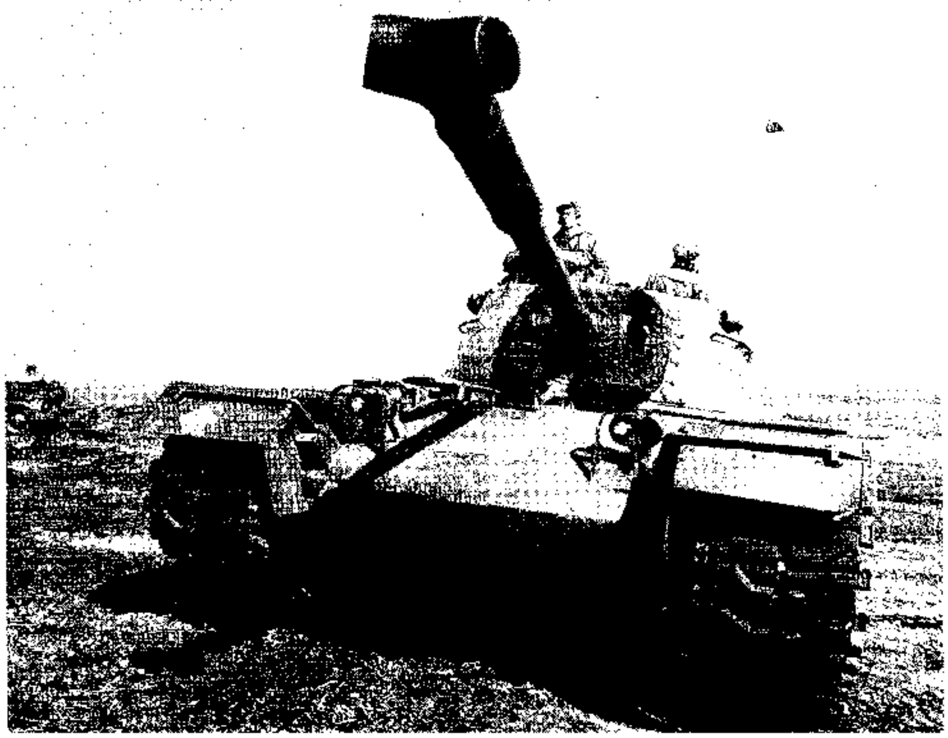
Night vision equipment: Driver's IR viewer can be fitted. A White light/IR search light can be fitted, for use in conjunction with IR gunner's and commander's sights.

Derivatives:

1. M48 Armoured Vehicle Launched Bridge. This carries a hydraulically launched scissors bridge which can be laid across ditches up to 18.29 m in width. It is very similar to the M-60 AVLB
2. The M88 Medium Armoured Recovery Vehicle uses many automotive components of the M48
3. All M-48s can be fitted with a dozer blade.
4. Flame-thrower tanks. Three separate marks have been developed, the M67, M67 A1 and M67 A2, none are at present in service.

STATUS:

The M48 is in service with Germany, Greece, Israel (some with 105 mm guns), Jordan, Norway, Pakistan, South Korea, South Vietnam, Spain, Taiwan, Turkey, Thailand and United States Army & Marines.



M-48A2 tank in German Army service

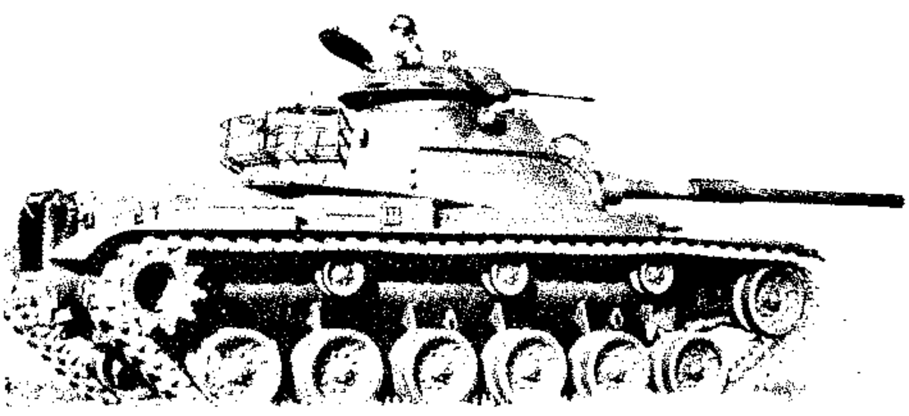
M48 Tank in service with the US Army

5024.102
M60 MAIN BATTLE TANK

DESCRIPTION:

M60 is the current main battle tank in service in considerable numbers in the US Army. It is a direct development of M47 and M48, the principal differences being the use of a diesel engine, giving a great improvement in range, a more powerful gun in the form of the British 105 mm gun, and additional armour protection, particularly on the turret. Development started in 1956, and the first production tanks were troop tested in 1959. Later production concentrated on M60 A1, which has a redesigned 'needle-nose' turret, and an improved gun control equipment, but is otherwise the same vehicle.

Now that the MBT70/XM803 tank has been cancelled the M60 will undoubtedly continue to be the operational main battle tank of the US Army for considerably longer than was originally envisaged. Consequently the Army has begun a product improvement programme for the M60 A1 version, which will extend over several years.



M60, early production series, during firing trials in May 1970

First stage in the programme was the incorporation of add-on stabilisation in a number of tanks in 1971. Other improvements will include the addition of a laser rangefinder, a solid-state ballistics computer, improved suspension, long-life tracks with replaceable pads, air cleaners and a more reliable engine and electrical systems.

In addition the Army requested funds in the Fiscal Year 1973 budget for prototyping and testing a thermal sight for the M60 A1. This sight, which will be mounted inside the turret and integrated with the fire control system, will help the crew to detect and engage targets in darkness or poor visibility conditions in daytime. The programme was expected to extend over two years and was aimed both at improving the M60 A1 and at establishing a design for subsequent tank development.

The product improvement programme for the M60 A1 has been under way since 1969 and will be carried out in three phases:

Phase 1 – The three main parts of this phase are the add-on stabilisation system, enabling the tank to have a shoot-on-the-move capability, and the new track, designated T-142, which will have twice the life of the T-97 track used at the present time. The vehicle will also be fitted with a top-loading air cleaner which increases engine life by reducing dust and dirt ingestion.

Phase 2 – This phase is scheduled to commence in 1976 and will involve installation of a laser rangefinder that can be used by both the commander and gunner by day and night; a solid-state computer will contain sensors for cross wind, vehicle cant, gun tube wear and ammunition grain temperature. The suspension will also be much improved by fitting the tube-over-bar suspension system, this will give the vehicle a significant increase in cross country mobility, a better gun platform and a smoother ride for the crew. The engine will be modified and improved by fitting a new turbo-charger, pistons and so on, and a new electrical system will be installed. This model will be known as the M60 A3.

Phase 3 – Work has started on this part of the programme and the improvements will include an engine with at least 900 hp coupled to a new four-speed hydrostatic transmission with new final drives. This will increase the acceleration as well as the top speed of the vehicle. Work has also started on a thermal night vision fire control system.

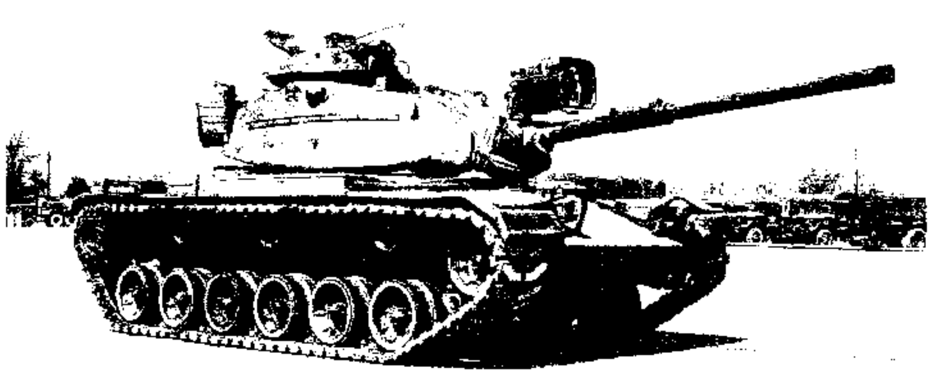
These phased improvements will be incorporated into production vehicles and have also been designed so that M60 A1s at present in service can be retrofitted as and when required.

STATUS

The M60 tank family will certainly continue to be the mainstay of the US armoured forces until the late 1970s. It is expected that the M60 A3 will be in production in FY 1975 after which existing stocks of M60 A1 will be progressively converted. In the meantime new procurement of M60 A1 will continue for replacement of obsolescent tanks in the US Army and the USMC.

CHARACTERISTICS (M60 A1):

Crew: 4 (commander, gunner, loader, driver)
Weight: 48 tons



M60 A1. The 'needle-nosed' turret is noticeable. The powerful Xenon IR / white light searchlight is fitted to the mantlet above the gun

Size: Height 3.26 m. Length (hull) 6.95 m. Width 3.63 m
Road speed / range: 48 km / h / 500 km
Main armament: 105 mm 51 calibre high velocity gun (British design, US manufacture) (**2451.103**)
Method of ranging: Monocular coincidence rangefinder with base of 2 m (But see text)
Armament: 63 rounds mixed APDS, HEAT, and HEP (equivalent to British HESH)
Secondary armament: 0.5 in commander's MG cupola mounted, with AA capability. 7.62 mm coaxial MG
Turret rotation: 360° electro-hydraulic or manual control
Engine: Continental 90° V-12 air cooled, twin turbocharged, diesel, 29.3 litres. 750 bhp at 2,400 rpm
Transmission: Allison hydraulic torque converter
Agility: Ground pressure 0.78 kg/sq cm. Max step 0.91 m. Max trench 2.58 m. Max gradient 60% (1 in 1.7). Ground clearance 0.46 m. Power-to-weight ratio 15.5 bhp/ton
Water crossing ability: Fording to 1.22 m without preparation. An appliqué schnorkel equipment permits fording to 4.11 m
Night vision equipment: A Xenon IR / white light searchlight can be fitted on the mantlet above the gun. Commander and gunner have interchangeable infra red sights. Driver has infra red viewer for use in conjunction with filtered headlights
NBC protection: Centralised filter system passes filtered air to the individual respirators of crew members.

DERIVATIVES

1. AVLB – Armoured Vehicle Launched Bridge on M60 A1 chassis can launch a 18 m bridge of classification 60 t in less than 2 minutes. Total weight 55 t. 2 man crew.
2. CEV – Combat Engineer Vehicle M728. Carries 165 mm demolition gun, winch with 11 t pull, an A-frame crane with 8 t lift, and a bulldozer blade. Total weight 50 t. 4 man crew.
3. The M60 A2 (separately described) is identical to M60 A1 below the turret ring.

STATUS:

The M60 and M60 A1 tanks are in service with Austria (120), Iran, Israel, Italy (200 M60 A1s have been built in Italy), Jordan, South Korea, Spain, Turkey and the United States. Future orders could come from Australia, Kuwait and Saudi-Arabia. The M60 A1 is in production by the Chrysler Corporation at the Detroit Tank Arsenal, which at the present time is the only tank plant in the USA. In the FY 1974 US Defence Budget a further 360 M60 A1s were to be built for the Army and 120 for the USMC. This total was increased by a supplemental to 613 (partly to cover sales to Israel) plus 155 covered by the proceeds of the sale of older tanks to Israel). For FY 1975 the purchase of 664 tanks – 154 M60 A1 for the USMC and 510 improved models for the Army – was proposed at an estimated cost of $229.2 million

MANUFACTURED BY:

Chrysler Corporation, PO Box 757, Michigan 48231, USA.

5025.102
M60 A2 (FORMERLY M60 A1 E2) MAIN BATTLE TANK

DESCRIPTION:

The M60 A2 tank (formerly known as the M60 A1 E2) is a basic M60 vehicle (**5024.102**) with the 105 mm turret replaced by a turret designed to house the XM 162 152 mm gun / launcher used with the Shillelagh missile (**2809.111**) but capable also of firing conventional 152 mm rounds.

The programme ran into design and engineering difficulties, and in 1969 official and service tests were suspended because of gun stabilisation and system reliability problems.

The turret is fully stabilised and incorporates for the first time an independently stabilised commander's cupola to provide a highly accurate shoot-on-the-move capability. The fire control system utilises a full solution ballistics computer coupled to a laser rangefinder, along with passive night vision for both the commander and gunner. With the exception of the missile, the commander has the same capability of aiming and firing all the weapons, day or night, with the same accuracy as the gunner. The commander has the capability of automatically lining up his cupola with the gunner to designate targets automatically to the gunner.

Over the next two years, however, these difficulties were overcome. In September 1971, the tank received Standard A classification and in

M60 A2 Tank, fitted with XM 162 gun / launcher system firing either the Shillelagh missile or a 152 mm high-explosive shell (US Army photograph)

November of that year it was decided that production and retrospective fitting could go ahead.

Procurement is now understood to be complete and it is believed that some 500 M60 A2 tanks have been completed. At least some of these are in service with US forces in Europe.

CHARACTERISTICS:
Crew: 4 (commander, gunner, loader, driver)
Weight: 58 tons
Size: Height 3.20 m. Length (hull) 6.95 m. Width 3.63 m
Road speed/range: 48 km/h/450 km
Main armament: XM 162 gun/launcher system (**2833.103**). Bore 152 mm
Method of ranging: Laser rangefinder
Ammunition carried: 13 Shillelagh missiles and 33 conventional rounds. Both systems use HEAT warheads as the principal anti-armour weapon
Accuracy and range: The range of Shillelagh is approximately 3,000 m. The conventional round, with a low muzzle velocity and short barrel lacks accuracy much above 1,500 m
Secondary armament: 0.5 in commander's MG cupola mounted, with AA capability. 7.62 mm coaxial MG
Turret rotation: 360°, electro-hydraulic or manual control
Engine: Continental 90° V-12 air cooled twin turbocharged diesel. 29.3 litres. 750 bhp at 2,400 rpm
Transmission: Allison hydraulic torque converter
Agility: Ground pressure 0.76 kg/sq cm. Max step 0.91 m. Max trench 2.58 m. Max gradient 60° (1 in 1.7). Ground clearance 0.41 m. Power-to-weight ratio 17 bhp/ton
Water crossing ability: Fording to 1.22 m unprepared. Prepared fording to 4.11 m
Night vision equipment: White light searchlight for use with daylight sights can be mounted on the left side of the turret. Passive night sights can be fitted for use of commander and gunner. Driver has IR viewer for use in conjunction with filtered headlamps
NBC protection: Centralised filter system passes filtered air to the individual respirators of crew members.

MANUFACTURER:
Chrysler Corporation, PO Box 757, Michigan, 48231, USA.

2853.102
XM-1 MAIN BATTLE TANK

DESCRIPTION
XM-1 is the successor of the cancelled US/FRG MBT-70 programme and the subsequent US-only XM-803 programme which was also cancelled. The reasons for cancellation mainly reflected over-specification leading to an unacceptably high unit cost. The sequence of programmes and cancellations is traced through the earlier editions of this book under entry number **5029.102**

Following the cancellation of the XM-803 project at the end of 1971 a task force was set up at the US Army Armour Centre at Fort Knox and required to make recommendations for a new design in August 1972. The XM-1 programme is the outcome of the activities of this task force

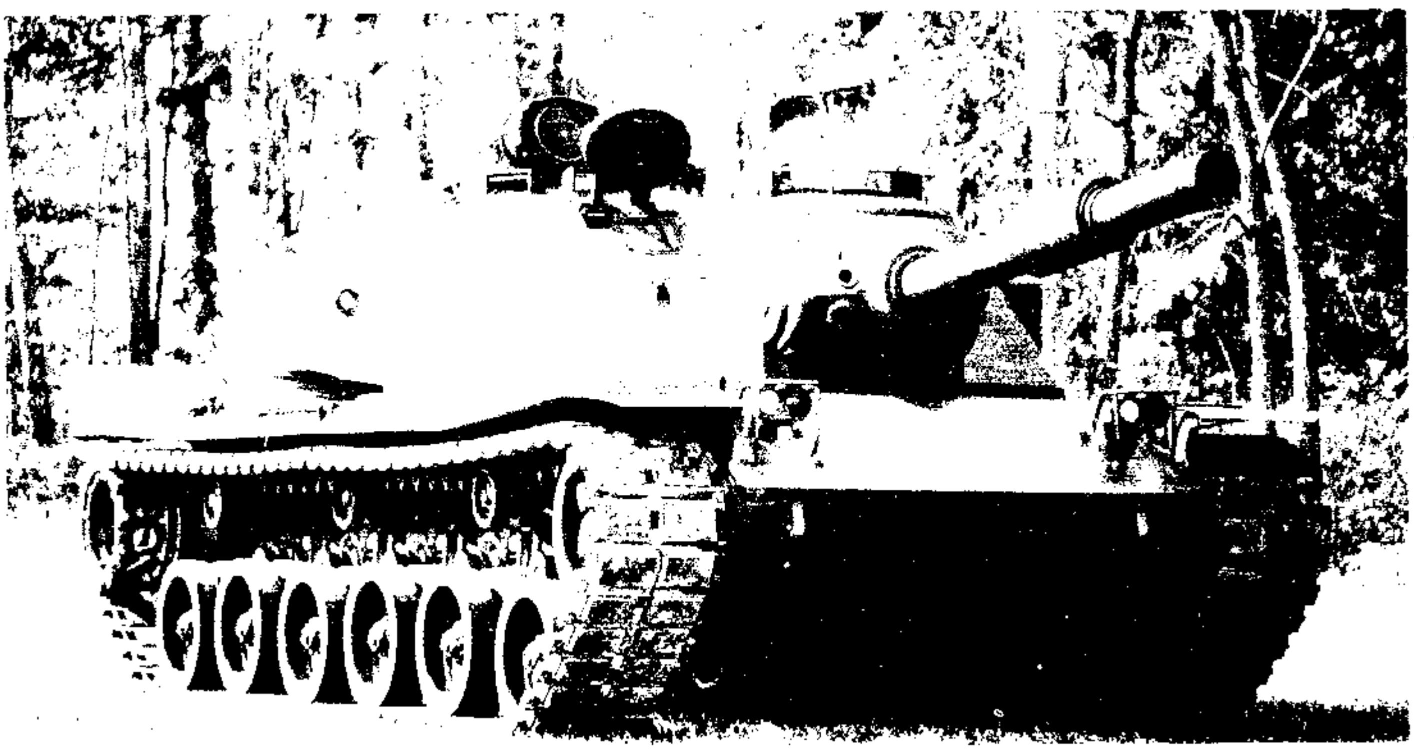
On 23rd January, 1973, the Project Manager of the XM-1 Programme, which is located at the Tank Automotive Command at Warren, Michigan, invited American companies to submit proposals for the new MBT. As a result of these proposals the Chrysler Corporation's Defense Operations Division (who build the current M60 A1 series) and the Detroit Diesel Allison Division of the General Motors Corporation, at Indianapolis, Indiana, (who built the MBT-70), both received contracts for the construction of one prototype tank, a mobility test rig, and a chassis and turret for ballistic tests. These should be completed by 1976/77 and tested for about three years: one of the companies will then be awarded a full development contract. The XM-1 is not expected to be in production until the early 1980's.

The Chrysler Company received a 34 month, $68.1 million contract of which some $8 million was for the further development of the Avco Lycoming AGT 1500 gas turbine which at present develops some 1500 hp with a further growth potential. The GMC vehicle will probably be powered by the Teledyne Continental engine, intended for the MBT-70, which developed some 1500 hp.

Very little information has been released on the XM-1 tank. In May, 1973, Brigadier General Robert J. Baer said "It will be well protected, with a low silhouette and good ballistic shielding against anti-tank weapons. Be fast and agile. Provide firepower options which are extremely effective even when on the move. Have good reliability to sustain it through long periods of combat with frequent engagements. Provide significant advances over the performance of the Army's present tank." On firepower, he said "(1) XM-1s weapons mix will provide a major gain in the tank's total battlefield potential. Complementing the main gun are a 20-30 mm coaxial cannon and two machine guns. (2). Increased range and lethality of the XM-1's complementary weapons against the wide range of soft targets will result in a kill factor five times greater than that of the Improved M60. (3). Fire control system will be similar to that of the Improved M60." He also said that XM-1 would have approximately the same weight (48 t) as the M60 A1, have much better acceleration (0-32 km/hr in less than 9 seconds) and be "75% more elusive" than the improved M60, and that the armour and compartmentalization of the XM-1 will make it "half as likely to be killed" if hit by enemy tank fire.

Prototypes will be armed with a 105 mm gun as used on the present M60 A1: production models will probably incorporate a 110 mm-120 mm gun: the 20-30 mm cannon is probably the Bushmaster at present under development for the ASRV: top road speed will be in the region of 75/80 km/hr. The US Army has a total requirement of some 3,300 XM-1s.

Acquisition cost is expected to be about twice that of the M60 A3. FY 1973 expenditure was $22 million: planned for FY 1974 $54 million: proposed for FY 1975 $69 million.



One of the MBT 70 tanks built in the international project which the XM-1 development replaces

5030.102
M551 SHERIDAN
LIGHT TANK

DESCRIPTION:

Sheridan is described by the US Army as an Armoured Reconnaissance Airborne Assault Vehicle (ARAAV). The emphasis nowadays is on the reconnaissance role, a role in which its high mobility is clearly important. Development started in 1959 against a specification which embodied two novel and important features: these were, first, the use of a dual-purpose gun and missile launcher – the missile being guided automatically to its target – and secondly, a combustible cartridge case to be used with the 152 mm anti-armour projectile. Associated with the first of these was, of course, the development of the missile itself – the Shillelagh (**2809.111**).

The combined gun/launcher was subsequently specified also for the M60 tank variant now known as the M60 A2 (**5025.102**) and for the ill-fated MBT-70 and XM-803 projects (**5029.102** and see **2853.102**). The latter projects had problems of their own which had nothing to do with the gun-launcher or the Shillelagh missile; it was the Sheridan project which had to bear the brunt of the criticism resulting from the teething troubles – both during development and when in service in Vietnam – which afflicted the innovations.

These criticisms have over the years diverted attention away from the good features of the Sheridan project. Sheridan is noted for its excellent cross-country mobility and the automotive side of the vehicle has been satisfactory. Following a modification programme to improve the reliability of the weapon system and provide better anti-mine protection the complete vehicle was operationally satisfactory: unfortunately, however, it had by then become an expensive vehicle and one that called for a high degree of crew training. It was therefore decided to limit procurement to a total of some 1,700 vehicles.

M551 Sheridan with XM 81 152 mm dual purpose gun/launcher

CHARACTERISTICS:

Crew: 4 (commander, gunner, loader, driver)
Weight: 15 tons (laden)
Size: Height (including MG) 3.0 m. Length 6.3 m. Width 2.8 m
Road speed/range: 70 km/h/600 km
Main armament: Gun launcher 152 mm M81
Method of ranging: Commander's estimation (an $8.3 million contract for the production of a laser rangefinder was awarded to Hughes in 1971)
Types of round: Shillelagh missile: Length 1.14 m. Weight 27.9 kg. Shaped charge warhead. Semi-automatic line of sight command guidance by Infra Red Command link. Maximum range 3,000 m. Conventional round: 152 mm diameter. HEAT warhead. Length 0.55 m. Weight 21.7 kg. Fully combustible cartridge. A canister round has also been developed
Rounds carried: 10 Shillelagh, 20 conventional
Secondary armament: One coaxial 7.62 mm MG. One 0.5 in MG on roof mounting for use by commander
Turret rotation: 360° in 10 seconds
Engine: GMC V-6 turbocharged compression ignition diesel, water cooled, 5.2 litres, 300 bhp at 2,800 rpm
Transmission: Hydraulic torque converter, with pivot steer capability
Agility: Ground pressure 0.48 kg/sq cm. Max step 0.84 m. Max trench 2.54 m. Max gradient 60°. Ground clearance 0.48 m. Power-to-weight ratio 20 bhp/ton
Water crossing ability: Swimming by the use of flotation screen permanently fitted, erected by crew in two minutes, gives 0.2 m freeboard. Water speed 5 kph
Night vision devices: Gunner and commander both equipped with passive image intensification night vision sights. Driver has active IR driving viewer, using filtered IR headlamps
NBC protection: An air filtration unit can be connected to the crew's face masks
Derivatives: It is believed that alternative turret arrangements include: 105 mm Howitzer, 155 mm Howitzer, Flame Thrower, Mortar carrier, anti-aircraft gun system and others. None are yet in service. The prototype of a bridgelayer on an M-551 chassis has been completed

STATUS:

Production complete. In service with US Army

MANUFACTURER:

Allison Division of General Motors, Indianapolis, Indiana, USA.

5033.102
V-100 COMMANDO M-706
ARMOURED PERSONNEL CARRIER

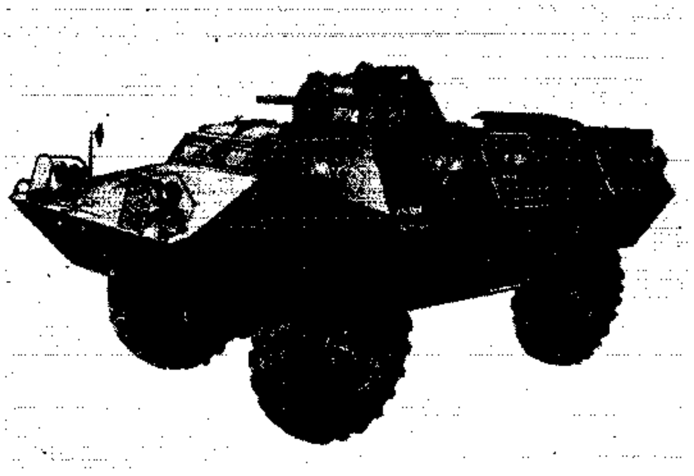
DESCRIPTION:

Developed between 1960 and 1965 as a private venture by the Cadillac Gage Company, to meet the requirements for a light, cheap, versatile armoured vehicle for convoy escort, police duties and border patrols. The high powered engine gives the vehicle a fast road speed and a good cross-country performance. It can swim unprepared, obtaining water traction from the spin of the wheels. Twelve firing ports in the hull enable the crew of 12 men to use their weapons from inside the vehicle. There are two versions. One with a rotating turret is capable of accepting a wide variety of weapon systems. The other version has a fixed roof, and is used purely as a personnel or load carrying vehicle. Several hundred of these vehicles have been manufactured. They are in service with the US Military and Air Force Police and the South Vietnamese Army in Vietnam, and are also in use in Lebanon, Malaysia, Muscat and Oman, Singapore, Somali and Sudan.

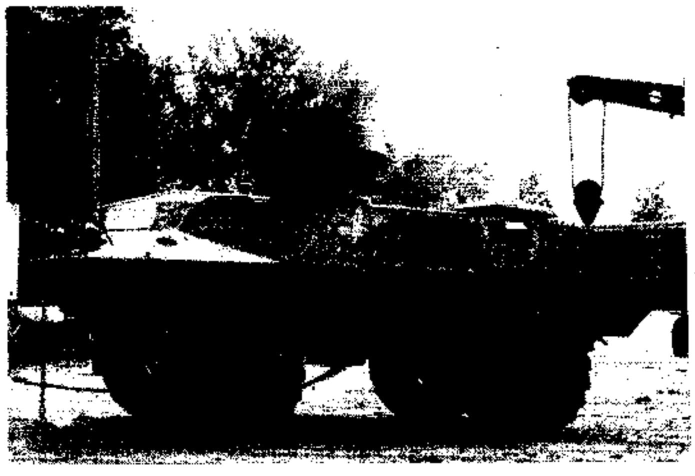
CHARACTERISTICS:

Crew: With rotating turret: 9 (commander, driver plus seven); without turret: 12 (commander, driver, plus ten)
Weight: 7.27 tons
Size: Length 5.68 m. Height (to top of turret) 2.44 m. Width 2.20 m
Road speed/range: 100 km/h/1,000 km
Armament: There are four established options for turret weapons and other possibilities have been explored:

1. Twin .30 in Browning MGs



M-706 Commando APC with twin .30 in Browning MGs in turret mounting



XM-706E1 – a version of the Commando APC with a 40 mm grenade launcher installation (US Army photograph)

2. Twin 7.62 mm Rheinmetal MG 42
3. One .50 in Browning MG and one .30 in Browning MG
4. One GE 7.62 mm Minigun

Ammunition: Option 1 and 2, 1,000 rounds Option 3, 200 rounds of .50, 500 rounds of .30, with additional ammunition storage in the body of the vehicle
Turret traverse: 360°, by handwheel
Engine: Chrysler V-8 361 petrol engine of 191 bhp
Transmission: Manual five speed synchromesh gearbox with single plate clutch
Agility: Max step 0.6 m. Max trench – only narrow ditch. Max gradient 60°. Ground clearance 0.4 m. Power-to-weight ratio 26.4 bhp/ton
Water crossing ability: Swims without preparation at 5 kmh, with a freeboard of 0.45 m
Additional equipment: A 5 ton winch is fitted at the front for self recovery

Product-improved M-706

Following the success of the M-706 in its original version the manufacturers have extended its range of capabilities by fitting it with a bigger engine (Chrysler 361 CID V-8 210 bhp with Allison 3-speed automatic transmission) and heavier duty (5 ton) axles. As a result the vehicle can carry an additional ton of payload.

With this improvement additional armament configurations have been developed. These include 20 mm and 90 mm two-man turrets, an 81 mm mortar version and an APC/Command version. A new twin M60 7.62 mm Cupola MG mounting in a balanced cradle has also been introduced. This has 400 ready rounds per gun and twelve grenade launchers are fixed to the turret and can be fired electrically from within. A communications slip-ring and coaxial spotlight have been added and the basket size increased to increase gunner efficiency.

MANUFACTURER:
The Cadillac Gage Company, PO Box 3806, Detroit, Michigan 48205, USA.

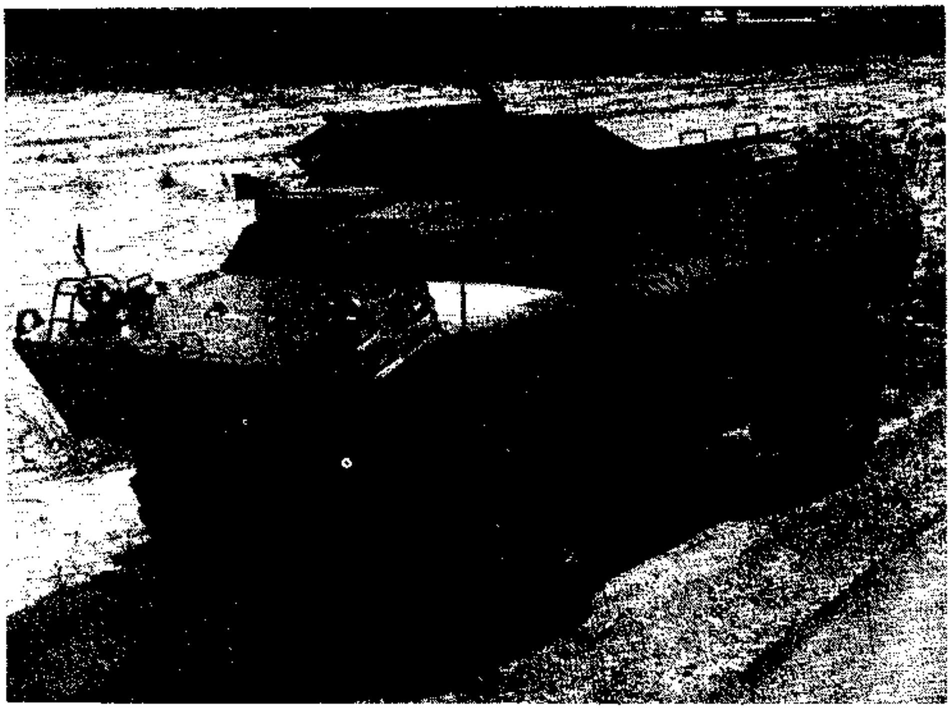
5066.102
V200 COMMANDO ARMOURED CAR

DESCRIPTION:

This vehicle has been developed from the lighter, smaller V100, and is available in a variety of configurations, as an armoured car with a 90 mm gun, or a 20 mm cannon, a personnel carrier carrying 12 men, a command vehicle, a recovery vehicle, or a mortar vehicle carrying either an 81 mm or 120 mm mortar. The 90 mm and 20 mm armoured car versions have been delivered to Singapore.

The 20 mm version is described below.

CHARACTERISTICS (20 mm cannon version):
Crew: 11 (commander, gunner, driver, co-driver plus 7 infantrymen)
Size: Height 2.7 m. Length 6.1 m. Width 2.4 m
Weight: (laden) 14.1 t
Road speed/range: 96 km/h/480 km
Armament: 20 mm cannon with coaxial 7.62 mm machine gun
Method of ranging: Commander's estimate
Rounds carried: 525 rds 20 mm, 5,000 rds 7.62 mm
Turret rotation: 360°, power assisted
Engine: Chrysler 440 diesel of 275 bhp
Transmission: Manual five-speed synchromesh gearbox with 2-speed transfer box to select forward and reverse. 4-wheel drive
Agility: Maximum step 0.61 m. Maximum trench – only very narrow ditches can be negotiated. Maximum gradient 60%. Ground clearance 0.43 m. Power-to-weight ratio 19.5 bhp/t
Water crossing ability: Amphibious, with 0.3 m freeboard. Propulsion by wheel-spin at 5 km/h
Additional features: Hydraulic winch at front with 6.8 t (nominal) line pull. Vision ports for crew through hull permit use of personal weapons from inside



V-200 Armoured Car with 81 mm mortar

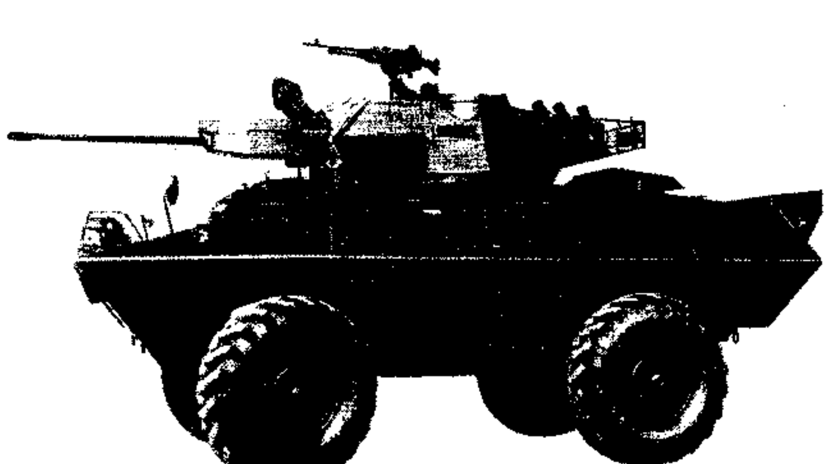
MANUFACTURER:
Cadillac Gage Company, PO Box 05006, Detroit, Michigan 48205, USA.

5078.102
V-150 COMMANDO ARMOURED PERSONNEL CARRIER

DESCRIPTION:

The V-150 was first shown in 1971 and its designed to fill the gap between the V-100 and V-200 vehicles. The hull is similar to that of the earlier V-100; but numerous improvements have been made including larger axles, increased wheel travel – and therefore improved cross country characteristics – improved brakes and brake failure warning system: a larger selection of engines (petrol or diesel) and transmissions (manual or automatic) can also be offered. Four basic models are available:

a. APC with a crew of two plus ten infantry. Armed with twin 7.62 mm MG or one 7.62 mm and one 12.7 mm MG plus smoke dischargers.
b. Mortar carrier with a crew of five and an 81 mm mortar.
c. Armed with a 20 mm Oerlikon gun in a turret with powered traverse and elevation, a co-axial 7.62 mm machine gun, a 7.62 mm anti-aircraft machine gun and smoke dischargers.
d. Armed with a turret-mounted 90 mm Mecar gun (**2491.103**), a 7.62 mm co-axial MG and a 7.62 mm anti-aircraft MG and smoke dischargers. Ammunition carried is 40 rounds of 90 mm, and 3,000 rounds of 7.62 mm.



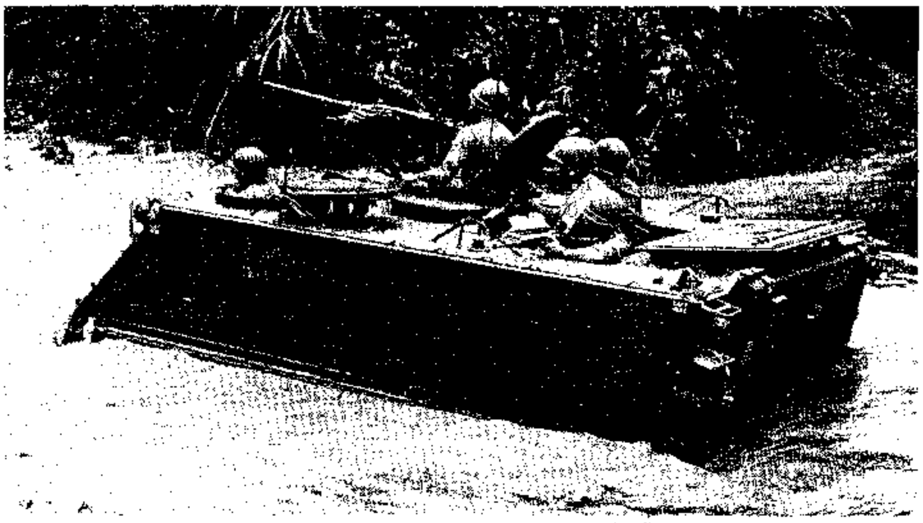
V-150 Commando with 20 mm cannon turret

Other models available include TOW missile carrier, command and recovery vehicles.

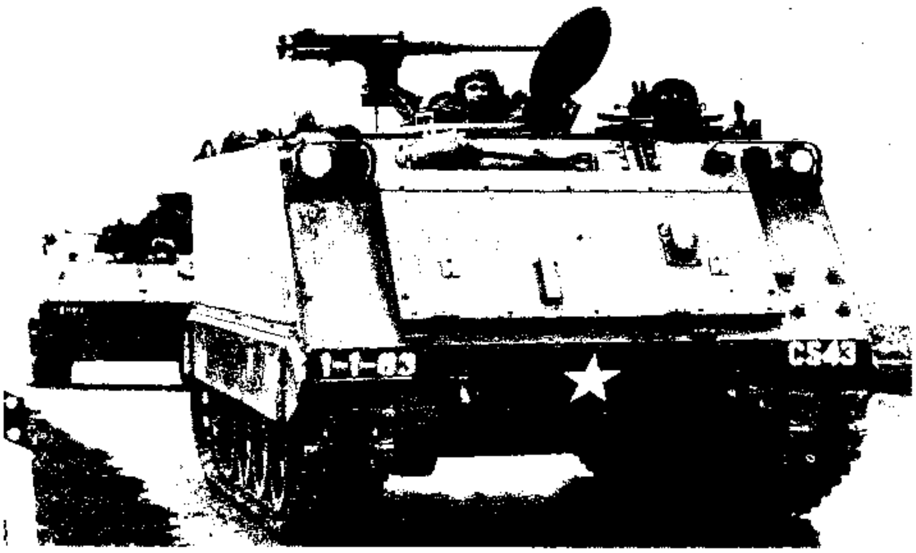
CHARACTERISTICS:
Crew: Commander and driver plus ten infantry (depending on role of vehicle)
Weight: 9.55 t
Size: Length 5.69 m. Width 2.26 m. Height 2.54 m (including turret)
Road speed/range: 89 km/h/960 km
Main armament: depends on role, various types up to 90 mm can be fitted
Turret rotation: 360° with power traverse, traverse speed is 60° a second
Engine: Chrysler V-8 petrol engine developing

210 hp at 4,400 rpm or a V 6 diesel developing 155 hp
Transmission: 5 speed manual gearbox, an automatic gearbox is also available
Agility: Ground pressure 0.8 kg/cm². Max step 0.61 m. Max gradient 60%. Ground clearances (axles) 0.38 m
Water crossing ability: Fully amphibious, propelled in the water by its wheels at 4.8 km/hr
Night vision equipment: Can be fitted if required
NBC system: Nil
Winch: A winch with a capacity of 9 t is fitted at the front
STATUS:
In production. Commando armoured cars are used by 21 countries.
MANUFACTURER:
Cadillac Gage Company, PO Box 05006, Detroit, Michigan, USA.

5016.102
M-113 ARMOURED PERSONNEL CARRIER
DESCRIPTION:
The M-113 is the current APC in US Army service. It is the most widely used armoured fighting vehicle outside the Soviet bloc, with over 44,000 vehicles or derivatives manufactured.
The specification, written in 1956, called for a lighter, simpler and less expensive APC than the M59 which had been in service since 1953. The FMC Corporation submitted the chosen design, and a contract for the delivery of 900 units was placed in 1959. Further orders of 2,823 for the US Army, and 1,132 for the West German Army followed almost immediately. The Swiss Army ordered 540 in 1963, and a quantity were manufactured for the Italian Army by OTO Melara of La Spezia (**5072.102**).
Since then sales have proliferated to Australia, Denmark, Greece, Holland, Iran, Korea, Pakistan, Spain, Thailand, Turkey and Vietnam.
A large number of derivatives have been produced incorporating every conceivable load and weapon system. The basic version mounts a 0.5 inch Browning MG externally on an unprotected commander's cupola. Operations in Vietnam led to the introduction of an armour-plated turret for the commander's cupola. The Australians in Vietnam fitted a Saladin turret complete with 76 mm gun and vehicles thus modified are now in service in Australia.
The M-113 was the first armoured vehicle to be constructed from welded aluminium plate armour. Its high vertical sides, which can be criticised for their vulnerability to anti-armour attack, give it the ability to float, even when fully loaded, with about 0.3 m of free-board. The interior is roomy; this not only makes for crew comfort, but also enables the vehicle to carry those additional stores and ammunition which can never be predicted and allowed for at the design stage. It is therefore popular with the crews who use it.
The back of the vehicle is a door, hinged at the base and forming a ramp which permits very rapid exit by the 11 infantrymen on board. Attempts have been made to provide firing ports through the side to enable the infantry section to use their weapons whilst still in the vehicle. This has not been entirely successful, because it has been US Army doctrine, unlike that of the West German Army, to use the APC as an 'armoured taxi' to carry the infantry on to the objective supported by fire from tanks, guns and helicopters, rather than expect the APCs to fight themselves on to the objective (but see **5055.102** below). These contrary views on the correct use of APC have produced two very dissimilar designs from the two countries.
There is nevertheless no doubt that the M-113 has been one of the most successful vehicles ever in the US Army service, and has proved especially valuable in the special circumstances of the Vietnam war. The original version has been replaced by M-113 A1, developed in 1964, with a more powerful diesel engine. Details of both marks are given below.
CHARACTERISTICS:
Crew: 13 (commander, driver, plus eleven infantrymen)
Weight: 10.67 tonnes (M-113 A1 10.93 tonnes)
Size: Height 2.2 m. Length 4.68 m. Width 2.69 m
Road speed/range: 64 km/h/320 km. Range of M-113 A1 is 480 km, speed 68 km/hr
Armament: Browning 0.5 inch MG on Commander's cupola
Rounds carried: 2,000
Turret rotation: No turret fitted except on specially modified versions



M-113 Armoured Personnel Carrier, crossing stream in Vietnam



M-113 APC on exercises in Germany in 1973 (US Army photograph)

A later version of M-113 in service in Vietnam. In the foreground is a M-113A1 with protective cupola and shields fitted. This vehicle is known as M113 ACAV and is fitted with a 0.5 in (12.7 mm) MG in the turret and two 7.62 mm MGs at the sides. In the background is a M-132A1 flamethrower (US Army photograph)

Armour: Welded aluminium plate
Engine: Chrysler 75 M 5,915 cc. V-8 water cooled, petrol, spark ignition. 209 bhp at 4,000 rpm (M-113). The M-113 A1 is powered by a GMC Model 6V53 diesel developing 215 hp
Transmission: Allison TX-200-2A (M-113 A1 – Allison TX100). Hydraulic torque converter with epicyclic gearbox giving 6 forward, one reverse, gears
Agility: Ground pressure 0.53 kg/sq cm. Max step 0.61 m. Max trench 1.67 m. Power-to-weight ratio 19.9 bhp/ton. M-113 A1 – 20 bhp/ton. Ground pressure 0.54 kg/cm^2
Water crossing ability: Inherently amphibious, propulsion by tracks at 3.5 mph
Derivatives: The most important amongst numerous local adaptations of the standard vehicle are: Two versions for mounting the ATGW SS11, and TOW. Two versions for mounting radars AN/TPS-25 and AN/PPS-4
Command Vehicle.
Recovery and repair vehicle
Two Mortar vehicles for 107 mm mortar and 81 mm Mortar.
Flame thrower.
Ambulance.
It is also widely used without seats as a universal loadcarrier.

M-113 chassis or components are also used in the following vehicles: Lance (**2682.111**), Chaparral (**2542.131**), Hawk SAM (**2640.131**) and the Vulcan Air Defence System (**2850.131**).

STATUS:
The M-113 and its numerous variants are used by Argentina, Australia, Bolivia, Brazil, Cambodia, Canada, Chile, Denmark, Ecuador, Germany, Greece, Iran, Israel, Italy, Laos, Lebanon, Libya (from Italy), Netherlands, New Zealand, Norway, Pakistan, Phillipines, South Korea, South Vietnam, Spain, Switzerland, Thailand, Turkey, United States and Uruguay.

A supplemental to the FY 1974 Defence Budget provided for the procurement for $44 million of 923 M-113 A1s. Some of these were to replace vehicles supplied to Israel in 1973; but the bulk were for replacement of the M-114 three-man command and reconnaissance vehicles (**5044.102**) which the US authorities say has proved difficult to maintain.

MANUFACTURER:
FMC Corporation, San Jose, California, USA.

5067.102
M-132A1 FLAME-THROWER

DESCRIPTION:
M-132A1 is a modified M-113A1 developed as a close range assault weapon for use by armour and mechanised infantry units. The M10-8 flame gun mounted in a special fully-rotating cupola is connected to four fuel tanks in the cargo compartment. The flame liquid can be discharged in bursts or continuously. There is a two man crew. The production contract for these vehicles was given to FMC Corporation in early 1963, and later that year the first experimental vehicles were deployed in Vietnam. Production versions of M-132A1 (diesel engine) were deployed in 1964, and production was completed in 1967.

CHARACTERISTICS (where they differ from M-113A1):
Crew: 2
Weight: 10.8 t
Flame-thrower: Effective range 150 m. 32 secs sustained duration.

The M-132A1 Flame-thrower, being demonstrated (US Army photograph)

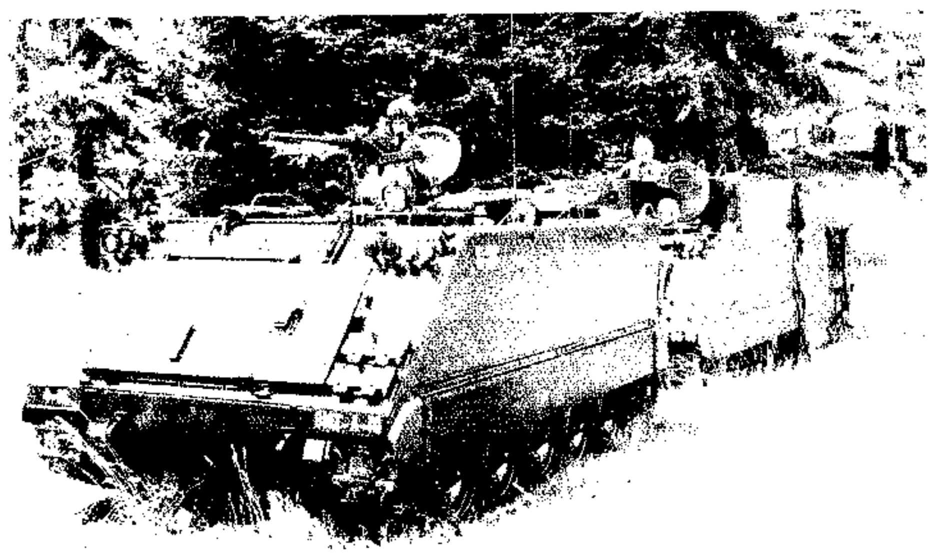
MANUFACTURERS:
Flame thrower: Consolidated Diesel Electric Corporation, Schenectady, New York, USA.
Vehicle: FMC Corporation, San Jose, California, USA.

5068.102
M-577A1 COMMAND POST VEHICLE

DESCRIPTION:
This vehicle is a derivative of the M-113A1 APC and is a mobile, self-contained command and control, communications and fire control vehicle for use by armoured and artillery formations and units. It can carry a wide variety of radio teletype and artillery control equipment. A penthouse tent can be erected at the rear of the vehicle to increase the working area of the five-man crew:

CHARACTERISTICS (where they differ from M-113A1):
Crew: 5
Weight: 11.0 t
Height: 2.68 m

MANUFACTURER:
FMC Corporation, San Jose, California 95108, USA.



A standard M-113 at the front contrasted with the M-577 Command Post Vehicle, with penthouse fitted, in the background (US Army photograph)

5069.102
M-106A1, M-125A1 MORTAR CARRIERS

DESCRIPTION:
These two vehicles are modified versions of the M-113A1 APC. M-106A1 is used as a firing platform and transporter for the 107 mm (4.2 inch) mortar, and M-125A1 for the 81 mm mortar. Both vehicles carry a crew of 6. Production of both vehicles began in 1964, and is still continuing.

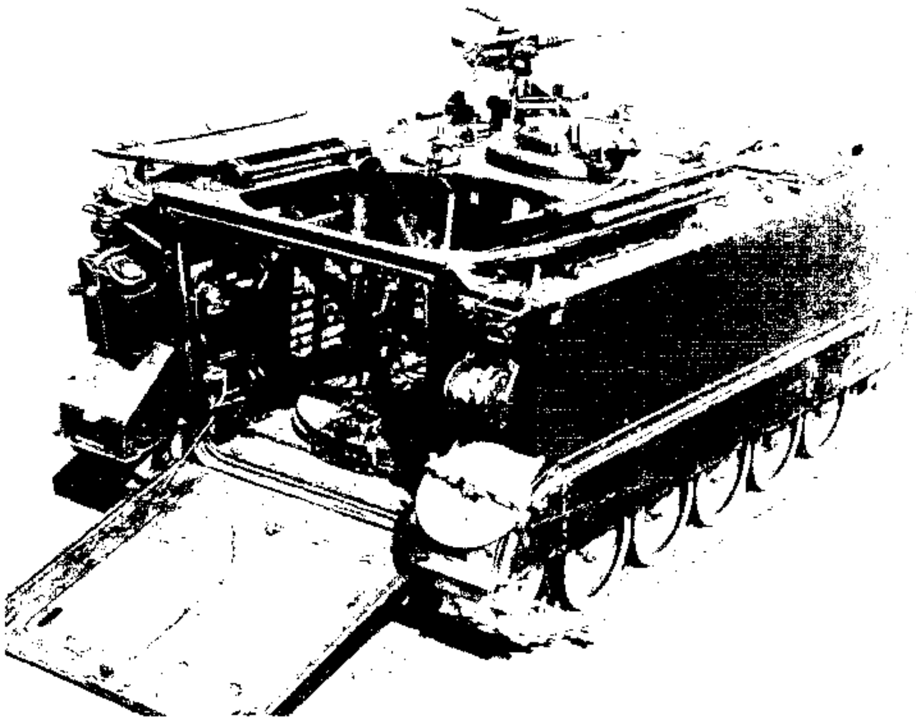
CHARACTERISTICS (where they differ from M-113A1):
Crew: 6
Weight: M-106A1 11.87 t. M-125A1 11.14 t

Armament: M-106A1, 107 mm mortar and 88 rounds. M-125A1 81 mm mortar and 114 rounds. Both vehicles also carry the 0.5 in Browning MG as on M-113A1

Traverse: In M-106A1 the traverse of the 107 mm mortar is restricted to 43° right and 46° left of the centre line. The mortar is fired over the rear of the vehicle. In M-125A1, the 81 mm mortar can be traversed through 360°

MANUFACTURER:

FMC Corporation, San Jose, California 95108, USA.



M-106A1 Mortar Carrier, with the 107 mm mortar in the firing position. The mortar can also be used dismounted using the baseplate shown fitted to the right hand rear track guard
(US Army photograph)

5043.102
COMMAND AND RECONNAISSANCE VEHICLE, C and R (LYNX)

DESCRIPTION:

This vehicle, variously known as M-113CR, M-113½, and Lynx was developed by FMC Corporation as a private venture from the M-113 Armoured Personnel Carrier. It is smaller, lighter, and more mobile than M-113, and with a gross weight of only 8.7 tons, is suitable for air lifting, para-dropping and amphibious operations. With a power to weight ratio of 25 bhp/t and a ground pressure of only 0.48 kg/cm², this vehicle has an exceptional cross-country mobility. Unlike the M-113, the engine and transmission is at the rear, insulating the crew from the noise and fumes, but resulting in the exit for the crew being either through the roof ports or through a small door on the right side of the vehicle. FMC Corporation put up this vehicle to the US Army as an alternative to M-114, but it was rejected. It has, however, been bought by the Canadian Army (174 vehicles) and by the Royal Netherlands Army (250 vehicles), and deliveries were completed in 1969.

CHARACTERISTICS:

Crew: 3 (commander, driver, observer/radio operator)

Weight: 8.78 tons laden

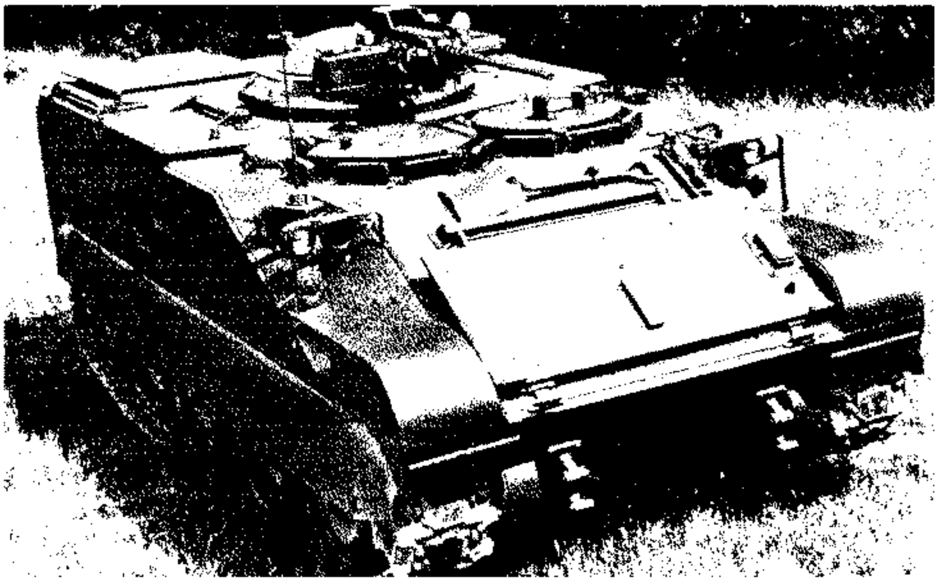
Size: Height 2.18 m. Length 4.60 m. Width 2.41 m

Road speed/range: 70 km/h/520 km

Armament: The standard vehicle has a 0.5 in Browning MG on Commander's cupola, and a 0.3 in MG on pivot mounting for the observer. Other variants exist (see below)

Rounds carried: Approx 1,100 rds 0.5 in or 2,000 rds 0.3 in

Cupola rotation: 360°, manual, with assistance from shoulder pads



Lynx in Canadian service

Armour: Welded aluminium plate

Engine: Detroit Diesel 6V53 V6 supercharged 2 stroke diesel water cooled, 5,210 cc, 215 bhp at 2,800 rpm

Transmission: Allison TX 100 torque converter, similar to that used in M-113. There are three forward and one reverse gear ratio

Agility: Ground pressure 0.48 kg/sq cm. Max step 0.61 m. Max trench 1.50 m. Max gradient 60% (1 in 1.5). Ground clearance 0.40 m

Power to weight ratio 25 bhp/ton

Water crossing capability: Inherent amphibian. Propulsion by tracks at 5.6 kph

Variants: A turret mounting a 20 mm cannon has been developed, increasing the height to 2.10 m. Other variants include versions for mounting a recoilless gun or an anti-tank guided weapons

MANUFACTURED BY:

FMC Corporation, San Jose, California 95108, USA.

5044.102
M-114
COMMAND AND RECONNAISSANCE CARRIER

DESCRIPTION

The requirements for this vehicle grew out of the need to replace the vulnerable Jeep and its 'soft skinned' counterparts with a better-protected and more mobile vehicle yet which was lighter, smaller and cheaper than the M-113 APC. M-114 was developed by the Allison Division of General Motors, to a US Army specification in competition with the M-113 CR vehicle put forward by the FMC Corporation. Production started in 1962, since when some 3,000 have been produced – production now being complete. It was deployed in Vietnam in 1965/66, but later withdrawn in favour of M-113 because of its relatively poor mobility in the special conditions of Vietnam. The original models used a 0.5 in Browning MG mounted on the commander's cupola but later versions have used a 20 mm Hispano Suiza cannon. Other weapon arrangements have also been tried

CHARACTERISTICS:

Crew: 3 (or 4 optional). Commander, driver, observer/radio operator, observer

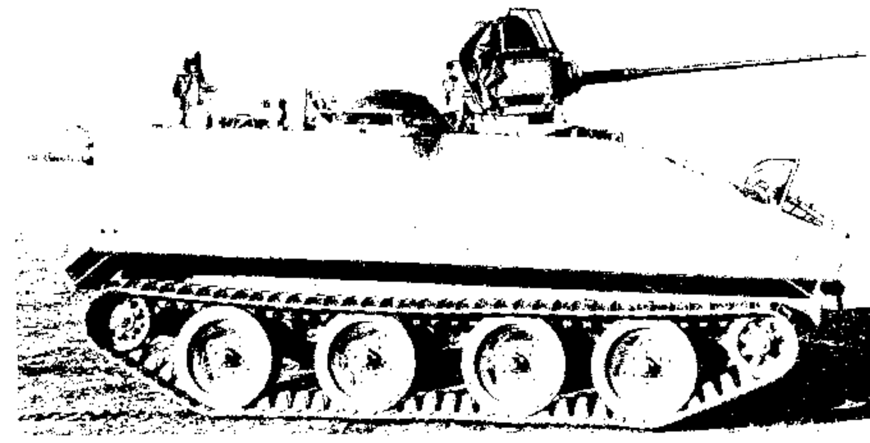
Weight: 6.85 tons

Size: Height 2.33 m. Length 4.46 m. Width 2.33 m

Road speed/range: 57 km/h/480 km
Armament: Browning 0.50 in MG in commander's cupola. 7.62 mm MG on front pintle mounting
Ammunition: 1,000 rds of 0.5 in
Turret rotation: M-114 Fixed cupola, commander must expose his body to fire MG. MG-114A1 – 360° cupola, with electrical firing gear, enabling commander to aim and fire whilst under armour
Armour protection: Welded aluminium plate
Engine: Chevrolet 90° V-8. 4 stroke spark ignition. 4,630 cc. Liquid cooled. 160 bhp
Transmission: GMC hydromatic, giving 4 forward and 1 manually selected reverse gears
Agility: Ground pressure 0.35 kg/sq cm. Max step 0.45 m. Max trench 1.52 m. Max gradient 44% (1 in 2.3). Ground clearance 0.41 m. Power to weight ratio 24 bhp/ton
Water crossing ability: Inherent amphibian. Propulsion by tracks at 4.8 kph
Night vision equipment: IR driver's and commander's viewers in conjunction with IR filtered headlamps
Variants: A variant mounting a 20 mm Hispano Suiza cannon has been developed and tested

Status:
In service, but scheduled to be replaced ultimately by the ARSV (see **5070.102** and **5125.102**). Because of maintenance difficulties some are being replaced by M-113A1 vehicles (see **5016.102**).

Manufacturer:
Allison Division of General Motors Corporation.



M-114A1 fitted with an Hispano Suiza 20mm cannon mounted on the commander's cupola and capable of being aimed and fired from under armour. This weapon is interchangeable with the normal 0.5 in Browning MG (US Army photograph)

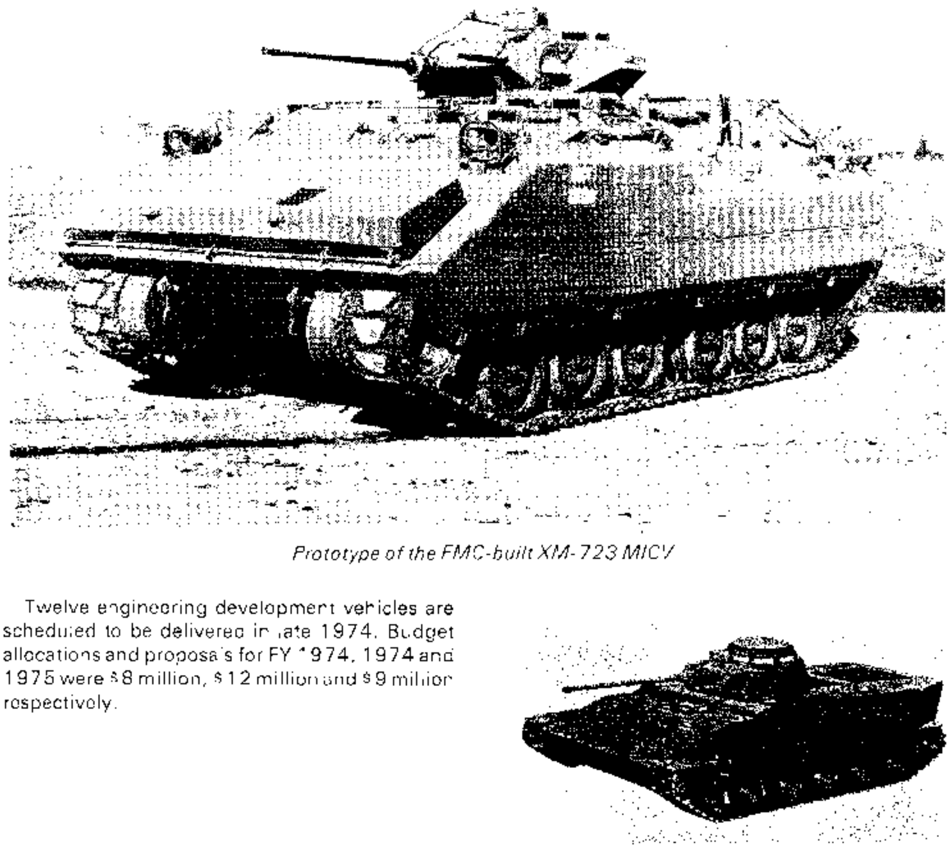
5055.102
XM 723 MECHANISED INFANTRY COMBAT VEHICLE (MICV)

Description:
The United States Army issued in 1972 a specification for a mechanised infantry combat vehicle (MICV). This specification resulted from the development of the US Army Tank/Infantry Doctrine that showed the need for an infantry vehicle from which the infantry could fight while protected from enemy fire.

In November, 1972, a development engineering contract was let to FMC Corporation, and as of winter 1973-74, one prototype and two automotive test rigs have been constructed and are undergoing extensive testing. The MICV is expected to provide high mobility, superior firepower, and more protection than any other infantry fighting vehicle in existence today. The MICV is powered by a Cummins VTA903 4-cycle diesel engine, coupled to a General Electric XM-2 hydromechanical automatic transmission. This power train provides 450 horsepower, allowing the MICV to keep pace with any of the MBTs in the inventory or projected for the near future. The vehicle weighs approximately 18.8 metric tons combat-loaded, it will cruise at 74 km/hr over a range of 480 km, and it is fully amphibious – water speed being 10 km/hr in the water.

The vehicle is armed with a 20 mm cannon mounted in an enclosed weapon station with a 360 degree continuous traverse and electrohydraulic stabilization. It is anticipated that production vehicles will be armed with the Bushmaster 20-30 mm cannon, when this is available. Secondary armament consists of a co-axial 7.62 mm machine gun. Squad members will fire M3A1 ball-mounted submachine guns through the six gun ports, two each side and two in the rear.

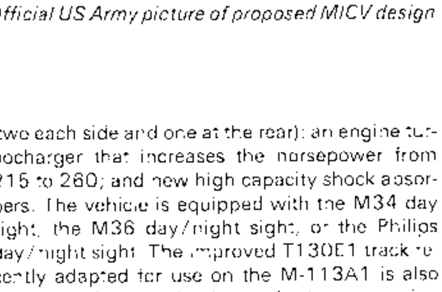
The MICV will provide more protection for its crew for less weight than any other comparable vehicle, with its aluminium and spaced laminate armour. It will carry an entire squad of infantrymen and deliver them to the battlefield in a ready-to-fight condition.



Prototype of the FMC-built XM-723 MICV

Twelve engineering development vehicles are scheduled to be delivered in late 1974. Budget allocations and proposals for FY 1974, 1974 and 1975 were $8 million, $12 million and $9 million respectively.

Manufacturer:
FMC Corporation, Ordnance Division, San Jose, California 95108, USA



Official US Army picture of proposed MICV design

5120.102
ARMOURED INFANTRY FIGHTING VEHICLE

Description:
In 1967, FMC Corporation built two XM765s for the United States Army. These vehicles used a number of M-113 components and were tested by the United States Army. FMC developed this vehicle further as a private venture, the end result being the AIFV, the first prototype of which was built in 1970. This has been tested in the USA and by the Belgian, Dutch and Italian Armies. The vehicle has been changed and improved in many ways, including spaced laminate armour attached to the hull; a power operated weapon station (turret) with a 20 or 25 mm automatic cannon and a co-axial 7.62 mm machine gun (alternative fits include a single 12.7 mm or 7.62 mm machine gun); five firing ports for the individual weapons (two each side and one at the rear); an engine turbocharger that increases the horsepower from 215 to 260; and new high capacity shock absorbers. The vehicle is equipped with the M34 day sight, the M36 day/night sight, or the Philips day/night sight. The improved T130E1 track recently adapted for use on the M-113A1 is also used. A unique torsion-bar-and-tube suspension system results in superior cross-country perform-

ance. The AIFV is fully amphibious, being propelled in the water by its tracks. It is fitted with infrared lights for night driving.

CHARACTERISTICS:

Crew: 10 (commander, gunner, driver, 7 infantrymen)

Weight: 12.7 tons (laden), 11.3 tons (empty)

Size: Length 5.36 m. Height 2.67 m (incl. turret). Width 2.85 m

Road speed / range: 62 km / h / 490 km

Armament: 20 or 25 mm automatic cannon, coaxial 7.62 mm machine gun

Rounds carried: 600 (20 mm) or 415 (25 mm)

Turret rotation: Continuous 360°, 45°/ second

Armour: Aluminium and steel

Engine: Detroit Diesel Model 6V53T 2-stroke turbo charged diesel, 5,210 cc, 260 bhp at 2,800 rpm

Transmission: Allison TX-100-1A single-stage automatic

Agility: Ground pressure (loaded) 0.62 kg/cm^2. Max step 0.64 m. Max trench 1.68 m. Max gradient 60%. Ground clearance 0.43 m. Gross horsepower-to-weight ratio 20.8 hp/ton; net horsepower-to-weight ratio 15.5 bhp/ton

Water crossing capability: Inherent amphibian. Propulsion by tracks at 5.5 km / hr

NBC System: Nil

MANUFACTURER:

FMC Corporation, San Jose, California 95108, USA.

AIFV with turret mounting 25 mm cannon

5070.102

FMC XM800 ARMOURED RECONNAISSANCE SCOUT VEHICLE (ARSV)

DESCRIPTION:

The Armoured Reconnaissance Scout Vehicle (ARSV) XM800 is a small, lightly armoured vehicle with exceptional mobility that will permit the US Army to carry out more effective reconnaissance missions either by day or by night. It will replace the M-114A1 (**5044.102**) at present used for this role. Normally, the ARSV will depend upon speed, agility, and quiet operation to accomplish its mission, but when necessary it will have firepower and armour to defend itself.

Both tracked and wheeled (**5125.102**) prototypes are being tested by the United States Army. The prime contractor for the tracked version is the Ordnance Division of FMC Corporation, with general Electric providing the turret power control and stabilisation, General Motors, Allison Division, providing the advanced hydrostatic steering transmission, and General Motors, Delco Electronics Division, providing the day / night sight.

The Detroit Diesel 6V53AT engine is coupled directly to the Allison X200 transmission. This power train is rear-mounted, and maintenance access points can be reached through the rear door.

The X200 hydrostatic steering transmission allows the ARSV to pivot about its own centre and permits excellent land and water manoeuvrability. The 12 inches of road wheel travel and the high power-to-weight ratio of 30 hp/ton provide fast response and high cross-country speeds. In addition to high-speed land travel, the ARSV swims at speeds of 7 km / hr, propelled only by its tracks.

A two-man, fully enclosed weapon station mounts a 20 mm M139 cannon and an auxiliary 7.62 mm M60D machine gun. The cannon is fired from inside the vehicle by the commander / gunner; the observer fires the auxiliary machine gun, which is on a skate mount around the observer's hatch, providing a 360° field of fire from an open hatch. Production vehicles will mount the Vehicle Rapid Fire weapon system (Bushmaster).

Prototypes of FMC's XM-800 ARSV

A 360° field of vision is provided to the commander by seven periscopes. The station is stabilised for both observation and firing by a General Electric all-electric power drive and stabilisation system (**2548.183**). A Delco Electronics day/-night sight provides 3x and 8x magnification for fire-control / surveillance capabilities from bright sunlight to starlight.

CHARACTERISTICS:

Crew: 3 (commander, observer and driver)

Weight: 8.25 tons

Size: Length 4.521 m. Width 2.438 m. Height 2.48 m

Road speed / range: 84 km / hr / 725 km

Armament: 20 mm M139 cannon and 7.62 mm M60D machine gun

Turret rotation: 360° powered traverse

Engine: Detroit Diesel 6V53AT, 300 hp at 2,800 rpm

Transmission: Allison X200

Agility: Max step 0.91 m. Gradient 60%. Ground clearance 0.406 m

Water crossing ability: Inherent amphibian. Propelled in the water by its tracks at 7 km / hr

STATUS:

Development. Defence budget funding for the two ARSV projects was $11.9 million in FY 1973, $10.4 million planned in FY 1974 and $33.4 million proposed for FY 1975 – including $25.3 million for the procurement of 35 vehicles. Note that these figures apply also to entry **5125.102**.

MANUFACTURER:

FMC Corporation, Ordnance Division, San Jose 95108, USA.

5125.102

LOCKHEED XM800 ARMORED RECONNAISSANCE SCOUT VEHICLE (ARSV)

DESCRIPTION:

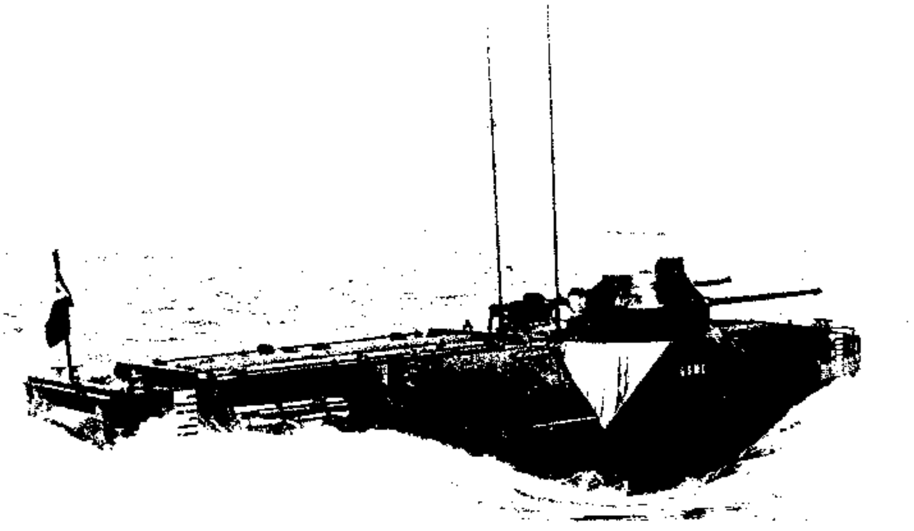
This is the wheeled model of the ARSV and has been developed under a $12.8 million contract awarded to the Lockheed Missile and Space Company. It is in competition with the FMC ARSV (**5070.102**). Three of these vehicles were handed over to the United States Army in the winter of 1973 / 74, as was a ballistic hull for test purposes; Lockheed retained one vehicle for test purposes.

The Lockheed development makes use of experience gained with their Twister 8 × 8 high mobility vehicle. Their ARSV entry is a 6 × 6 vehicle and has independently sprung walking beam suspension, roll-articulated front and rear bodies, and low pressure types. The vehicle is fully amphibious, being propelled in the water by waterjets. For US defence budget allocation see **5070.102**.

CHARACTERISTICS:
Crew: 3 (commander/gunner, observer, driver)
Weight: 7.7 tons
Size: Length 4.914 m. Width 2.438 m. Height 2.489 m
Road speed/range: 104 km/h/725 km
Armament: 20 mm M139 cannon and 7.62 mm M60D machine gun
Ammunition: 500 rounds of 20 mm and 2,000 rounds of 7.62 mm
Turret rotation: 360°, powered traverse
Engine: Detroit Diesel (turbocharged) Model 6V53T developing 280 hp at 2,800 rpm
Transmission: 5 speed automatic transmission
Agility: Max step 0.91 m. Gradient 60%. Ground clearance 0.41 m
Water crossing ability: Inherent amphibian, propelled in the water by water jets.
MANUFACTURER:
Lockheed Missiles and Space Company, Ground Vehicle Systems, Sunnyvale, California 94088, USA.

5071.102
LVTP 7
LANDING VEHICLE TRACKED PERSONNEL

DESCRIPTION:
The LVTP 7 is the US Marine Corps' latest amphibious assault vehicle. It was formerly known as LVTPX 12 and has replaced the LVTP 5, which has been in service since 1955. It is designed to transport 25 troops or 4.5t of stores onto beaches with slopes of up to 60%, and through surf of 3 m height. It is capable of continuing in the support role onto inland objectives. The hull is of welded aluminium plate, which reduces the combat weight to 22.6 t. The power from the diesel engine can either drive the tracks or be taken to the water jets, which can deliver a total thrust of 2t. The FMC Corporation were contracted to produce fifteen prototype LVTPX 12 vehicles by 1964, and these vehicles were very extensively tested at various tropic, arctic and temperate sites up to March 1969. The FMC Corporation were awarded a production contract in June 1970 for the production of 942 vehicles at a cost of $78.5 m. First deliveries began on schedule in August 1971, and the first 35 vehicles were assigned to the training base. Initial delivery to Marine field units began early in 1972 and the first Fleet Marine Force company to be equipped with the vehicle was activated on 31st March.

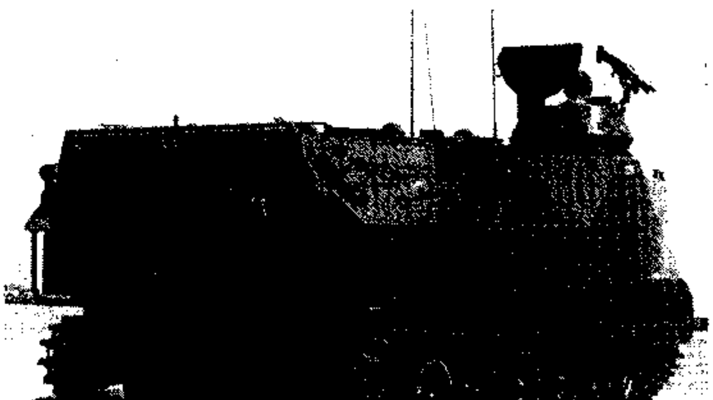


A production LVTP7 at sea. The impressive top speed in water of 13.5 km/h is well illustrated here

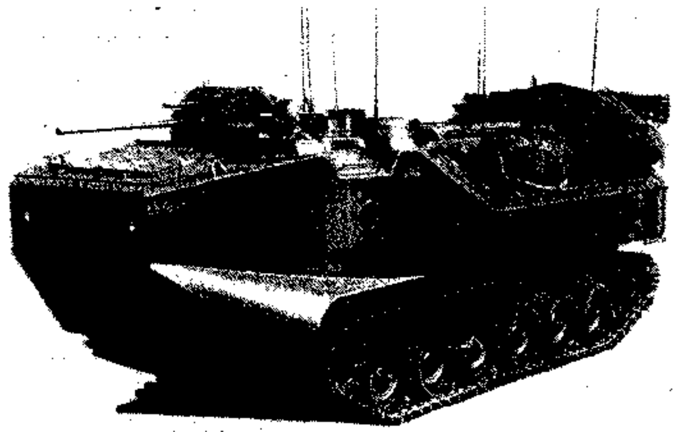
CHARACTERISTICS:
Crew: 3 plus 25 infantrymen
Weight: 23.66 t
Payload: 4.5t
Size: Height 3.26 m. Length 7.94 m. Width 3.27 m
Speed: Land 64 km/h. Water 13.5 km/h
Range: Land 480 km. Water 113 km
Armament: 12.7 mm M-85 MG: elevation +60°, depression −15°
Engine: General Motors diesel 8V53T of 6.9 litres, 406 bhp. The engine is in the bow section
Transmission: FMC HS 400 giving 4 forward, 2 reverse ratios. Power assisted, manually controlled
Agility on land: Ground pressure 0.58 kg/cm². Maximum step 0.9 m. Maximum trench 2.4 m. Maximum gradient 60%. Power to weight ratio 18 bhp/t
Exit: By tail gate, hinged against a water-tight seal.
Special Equipment:
1. An internal heater can keep crew compartment up to 26°C above the outside temperature.
2. A stretcher kit will provie for up to six stretcher cases.
3. Navigation lights are provided for coastal waters.
4. An arctic cupola provides protection for the driver in driving snow conditions.

VARIANTS:
1. LVTR 7 – Recovery vehicle (formerly LVTRX 2). Designed to recover similar vehicles from the open sea, surf or from swamps. Testing of two prototypes was completed in early 1970 and procurement was approved in April 1970.
2. LVTC 7 – Command/Communications Vehicle (formerly LVTCX 2). A mobile command post. Prototype testing was completed in early 1970 and procurement was approved in September 1970.
3. LVTE 7 – Mine and obstacle clearing vehicle (formerly LVTEX 3). To clear beaches during an amphibious assault. A linear charge to clear minefields is fired by rocket A bulldozer blade is fitted. Prototype testing was completed in April 1971. Procurement was approved but was subsequently cancelled.

STATUS:
LVTP-7s have now replaced all LVTP-5's in the United States Marine Corps. Production of the LVTP-7 is scheduled to continue until September 1974. The LVTP-7 has also been ordered by Italy and Spain.
MANUFACTURER:
FMC Corporation, San Jose, California 95103, USA.



Prototype LVTP-7 vehicle (USMC photograph)



Prototype LVTC-7 vehicle

THE UNION OF SOVIET SOCIALIST REPUBLICS

5112.102
T-70 MAIN BATTLE TANK
DESCRIPTION:

The T-70 is the new Soviet MBT which has started to replace the T-62 (**5047.102**) and which was previously known as the T-64 or M-1970.

It is believed that the T-70 entered production in 1970/71. Few details are available at the present time. Some reports suggest that it is armed with the same 115 mm gun as is fitted to the T-62, but others have suggested that it has a 122 mm gun. The chassis is new and is a departure from established Soviet practice: the suspension consists of six evenly spaced road wheels and four track support rollers – very similar, in fact, to that used on the Ganef missile carrying vehicle (**2934.131**) and the new tracked armoured minelayer, although both of these vehicles have seven road wheels. The glacis plate of the T-70 is well shaped and similar to that of the British Chieftain; the driver is in the centre – again similar to the Chieftain. The turret is similar to that of the T-62. The infra-red light for the commander is on the right turret hatch and the infra-red light for the gunner is on the left of the main armament – i.e. the reverse of the arrangement on the T-62. This indicates that the armament may well be different from that fitted to the T-62.

STATUS:

In service with the Soviet Army.

5047.102
T-62 MAIN BATTLE TANK
DESCRIPTION:

The T-62 is a logical development of the T-54/T-55 tanks which entered production in 1961/62. It has a wider and longer hull than those of the earlier tanks and has a new turret mounted slightly more to the rear. The main improvement over the earlier T-54/T-55 is that the T-62 has been fitted with the new 115 mm U-5TS (**2972.103**) smooth bore gun which fires a APFSDS (Armour-Piercing Fin Stabilised Discarding Sabot) round. The T-62s main armament is, like the earlier T-54/T-55, limited in gun depression.

Standard equipment on the T-62 includes the vulnerable external fuel tanks, NBC system, infra-red driving and fighting equipment and the capability to lay its own smoke screen. A more recent model of the T-62 is the T-62A; this is fitted with a 12.7 mm DShK anti-aircraft machine gun.

CHARACTERISTICS:

Crew: 4 (commander, gunner, loader, driver)
Weight: 37.5 tons
Size: Length (hull) 6.705 m. Width 3.352 m. Height 2.40 m
Road Speed: 55 km/hr
Road Range: 480 km
Main Armament: 115 mm smooth bore gun
Elevation/depression: +15°, −3°
Max anti-armour range: Not known, but unlikely to be in excess of 1,500 m owing to inaccuracy inherent in fin-stabilised rounds about that range
Method of Ranging: Stadiametric range finder in commander's sight. A laser rangefinder is believed to be under development
Rate of fire: 5 rounds per minute (maximum)
Ammunition: 40 rounds of HE, HEAT and APFSDS rounds carried
Turret traverse: 360°
Secondary Armament: 7.62 mm PKT co-axial machine gun. 12.7 DShK anti-aircraft machine gun
Engine: Model V-2-62, V-12 water cooled diesel, 700 hp at 2,200 rpm
Agility: Ground clearance 0.425 m. Ground pressure 0.8 kg/cm^2. Gradient 60%. Max step 0.8 m. Max trench 2.8 m
Power to weight ratio: 15.6 bhp/ton
Water crossing ability: 1.40 m without schnorkel, 3.96 m with schnorkel
Night vision equipment: A full range is fitted

T62A tanks on an exercise

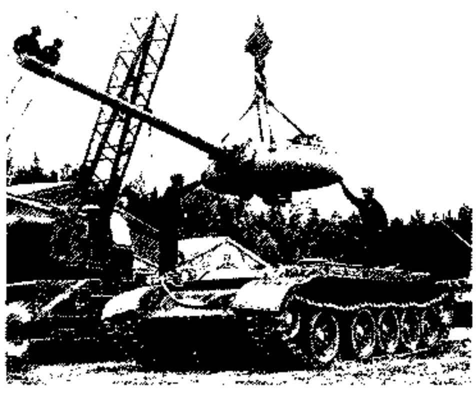
T62 tanks on a demonstration. The compact design of the turret, and the fume extractor on the 115 mm smooth bore gun can clearly be seen (Tass)

STATUS:

In production and service with Bulgaria, Czechoslovakia, East Germany, Egypt, Hungary, India, Poland, Romania, Soviet Union, Syria.

5049.102
T54/T55 MAIN BATTLE TANKS
DESCRIPTION:

The T55 is essentially a later mark of the T54, so these two tanks can be considered together. The T54 has been produced in greater quantity than any other tank in the world. It is believed some 30,000 of them were manufactured between 1948 and 1963, of which perhaps 5,000 to 6,000 were at one time stationed in East Germany. All the Warsaw Pact countries were equipped with these tanks, as was the United Arab Republic before the 1967 war, and Cuba in the early 1960s. Large numbers are still in service, although the regular Soviet Army has largely been re-equipped with T62s. At the time it was developed it was in the forefront of tank development, and its arrival into the Soviet Army inventory posed a challenge and a threat to the NATO powers. The design achieves the considerable feat of incorporating a 100 mm high velocity gun into a 35t low silhouette, long range and high mobility chassis. The armour protection is poor by Chieftain, Centurion and M60 standards, being about 85 mm of armour on the front plate of the hull, and 100 mm of armour on the front of the turret. This is to some extent compensated by the good ballistics shape of the turret, and the low silhouette. The turret as a result is cramped which makes for a



Tank repairs in the field (Tass)

A T54B leads two T54As over a water obstacle on exercise

slow rate of fire. The gun control equipment is crude by western standards, and throughout the tank the finish of the workmanship is rough. This certainly results in cheaper production costs, estimated at 40% to 50% of the cost of equivalent western tanks. The mobility of this tank is good, and its long range endurance is quite exceptional.

CHARACTERISTICS (Apply to T54 and T55 except where stated).

Crew: 4 (commander, gunner, loader, driver) N.B. The loader's position is on the right of the gun

Weight: 36.5 tonnes

Size: Length 9.02 m (gun forward), 6.57 m (hull) Width 3.27 m. Height 2.40 m (w/o AA MG)

Road speed: 48 km/hr

Range: 630 km road and 440 km cross country (including external tanks)

Main armament:
T-54 100 mm gun model D-10T
T-54A 100 mm gun model D-10TG
T-54B 100 mm gun model D-10T2S
T55 100 mm gun model D-10T2S
(see **2966.103**)

Elevation/depression: +17°, −4° (depression is very small by western standards)

Max anti-armour range: 1,000 m using AP or HEAT rounds

Method of ranging: Gunner has sight TSchZ-22 and a TTSch-16 as a secondary sight, commander has TPK-1 panoramic telescope

Rate of fire: 3 to 5 (maximum) rounds a minute

Ammunition: T-54 a total of 34 rounds and T-55 a total of 43 rounds (AP, APC, HVAP, HE and HEAT)

Turret traverse: 360° by power traverse

Secondary armament: 7.62 mm SGMT machine gun co-axial with main armament, 12.7 mm DShK anti-aircraft machine gun on roof of vehicle and a 7.62 mm SGMT machine gun mounted in bow and operated by the driver (not on T-55)

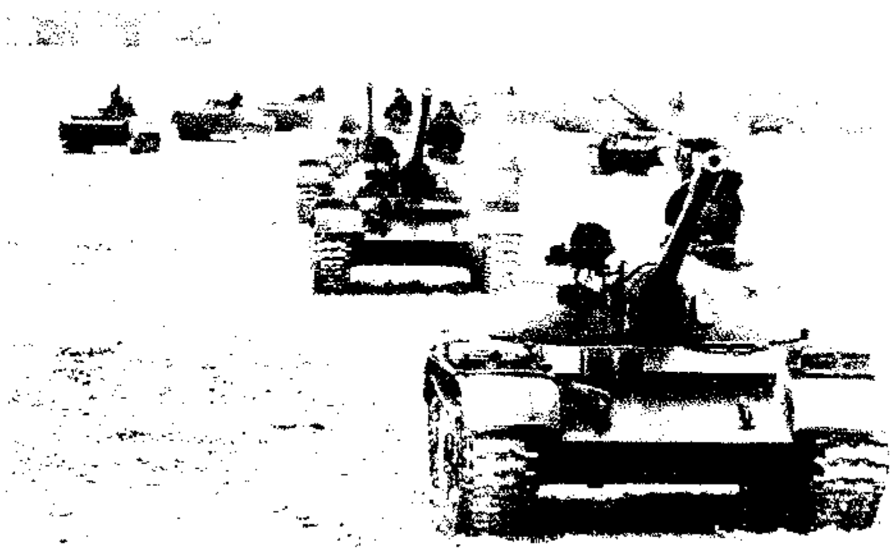
Engine: T-54 has V-2-54, V-12 water-cooled diesel, 520 hp at 2,000 rev/min. T-55 has V-2-55, V-12 water-cooled diesel; 580 hp at 2,000 rev/min

Transmission: Conventional manual gearbox with multi-plate clutch. Five forward, one reverse, gears

Agility: Ground pressure 0.80 kg/sq.cm. Max trench 2.74 m. Max gradient 60%. Ground clearance 0.43 m. Power-to-weight ratio 14.5 bhp/ton (T-54) and 16 bhp/ton (T-55)

Water crossing ability: Wades unprepared to 1.50 m. Schnorkelling equipment enables depths up to 5.4 m to be crossed at speed of 2 km/h. The equipment takes about 15 minutes to prepare, but can be blown off with an explosive charge immediately on leaving the water

Night vision equipment: Has been introduced



T55 tanks on exercise with M-1967 APCs in the background (Tass)

T54 tanks on winter exercises (Tass)

progressively in successive marks of T 54. Driver has infra-red viewer with range of 60 m; commander has infra-red/white searchlight; gunner has infra-red searchlight and infra-red driving lamps.

NBC Protection: Interior of tank can be pressurised, with incoming air pressure passing through a filter to the crew.

VARIANTS:

Summarising the main points of difference in marks, using the NATO designations.

T54. No muzzle bore evacuator. Bulge aft of the turret. 144 road wheel pattern.

T54A. Introduced in 1956. Muzzle bore evacuator fitted. Full hemispherical shape to turret. New road wheels. Gun stabilised in elevation.

T54B. Introduced in 1959. Improved gun sight and optical rangefinder noticeable by increased size of gun sight fairing forward of the commander's cupola.

The IR searchlight mountings, which were sometimes taken to distinguish different marks of T54, are now thought to be transferable to all T54 marks.

T55. No MG fitting on loader's hatch. Improved fittings for 'Snorkel' tower for deep wading. IR searchlight can be linked to gun tube.

Variants based on the T54/55 chassis include:

SU57: Anti aircraft tank.

T54 MTU: Bridge layer, capable of laying a 12 m bridge of capacity 50 t.

Mine roller: For clearing minefields.

Engineer tank in various forms as bulldozer, crane and tractor.

Repair/Recovery tank.

STATUS:

The T-54/T-55 is no longer in production. In addition to being built in the Soviet Union it has also been built in Czechoslovakia, Poland and China (under the designation T-59 **5042.102**). T 54/T 55 tanks are used by Albania, Algeria, Afghanistan, Bulgaria, China, Cuba, Cyprus, Czechoslovakia, East Germany, Finland, Egypt, Hungary, India, Iraq, Israel, Libya, Mongolia, Morocco, North Korea, North Vietnam, North Yemen, Pakistan, Peru, Poland, Romania, South Yemen, Soviet Union, Sudan, Syria, Yugoslavia.

5048.102

T-10 HEAVY TANK

DESCRIPTION

The T-10 replaced the JS-111 (**2288.102**) in the Russian Army in the 1950's. It is no longer in large scale use with the Army, although large numbers of them are held in reserve; it does however, remain in service with many members of the WPF as well as some Middle East countries. The original T-10 was armed with a 122 mm gun, a 12.7 mm M1938/46 DShK MG and a similar anti-aircraft MG. The later model was the T-10M, the improvements of which over the earlier T-10 included the replacement of the 12.7 mm MGs by 14.5 mm KPV MGs, the fitting of infra-red driving and fighting equipment and the fitting of a stowage box on the turret rear (not all models). Some T-10Ms have been fitted with a schnorkel and have a stabiliser for the main gun.

Although the T-10 is classed in the West as a heavy tank it should be remembered that it is in fact lighter than the British Chieftain and only slightly heavier than the American M60A1 however, the T-10 does lack mobility. The 122 mm gun fires separate loading ammunition, which accounts for its low maximum rate of fire of three rounds a minute. The T-10 was found to be a difficult tank to destroy by the Israelis in the 1967 campaign, its armour (maximum is 210 mm) was difficult to penetrate, but the auxiliary fuel tanks at the rear were highly vulnerable.

CHARACTERISTICS:

Crew: 4 (commander, gunner, loader, driver)

Weight: 49 tonnes

Size: Length 10.29 m (including gun), 7.40 (hull). Width 3.44 m. Height 2.26 m (w/o A/A MG)

Road speed/range: 35 km/350 km

Main armament: 122 mm gun

Elevation/depression: +17°, −3°

Rate of fire: 3 rounds a minute

Ammunition: 30 rounds of HEAT, HE and APHE. HEAT projectile weighs 14.1 kg and has a M/V of 900 m/s; HE projectile weighs 25.5 kg and has a M/V of 800 m/s, APHE projectile weighs 35 kg and has a M/V of 905 m/s. APHE has an effective range of 1,200 m

Turret traverse: 360° by power traverse

Secondary armament: 14.5 mm KPV co-axial MG and 14.5 mm KPV anti-aircraft MG (on T-10M)

Engine: Model V-2-IS, 12 cylinder water cooled diesel 690 hp at 2,000 rpm

Transmission: Manual gearbox with 5 forward and 1 reverse gears

Agility: Ground pressure 0.71 kg/sq cm. Step 0.9 m. Max trench 3 m. Max gradient 60%. Ground clearance 0.456 m. Power-to-weight ratio 13.6 bhp/ton

T-10 heavy tank

Water crossing ability: Wades to a depth of 1.2 m, some T-10Ms can be fitted with a schnorkel

Night vision equipment: Driver has IR viewer, commander has IR searchlight with range of 500 m, gunner's IR light has range of 1,000 m

NBC Protection: A NBC system is fitted

STATUS:

In service with Bulgaria, Czechoslovakia, East Germany, Egypt, Hungary, North Vietnam, Poland, Romania, Soviet Union and Syria.

2288.102

JS III HEAVY TANK

DESCRIPTION:

Developed from the earlier JS (Joseph Stalin) I tank, the JS III entered service in 1945. Now superseded by the T-10 (**5048.102**) and later tanks in all major formations, the JS III still exists as a tank in some of the Warsaw Pact states, its chassis exists in rather more places because of its use as a missile carrier.

CHARACTERISTICS:

Crew: 4

Weight: 4.6 t

Size: Length 9.6 m (gun forward) 6.8 m (chassis only. Width 3 m. Height 2.44 m

Main Armament: 122 mm gun 25 rounds carried

Secondary Armament: 7.62 mm coaxial MG 12.7 AA MG

Engine: V-12 diesel 520 hp

STATUS:

Although obsolete in Russia the JS III remains in service with Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Romania and Syria.

5113.102

M-1970 LIGHT TANK

DESCRIPTION:

This new Soviet light tank was shown for the first time in November, 1973, although it has been in service for at least two years. It is fully amphibious being propelled in the water by waterjets. A turret similar to that fitted to the BMP 76PB (**5054.102**) is mounted in the centre of the vehicle. A Sagger ATGW is mounted over the 76 mm gun and a 7.62 mm MG is probably fitted. A crew of three is carried and there is a personnel compartment for six men behind the turret. At the time of writing the exact role of the M 1970 is uncertain, but it is known that it has entered service with Soviet airborne units.

STATUS:

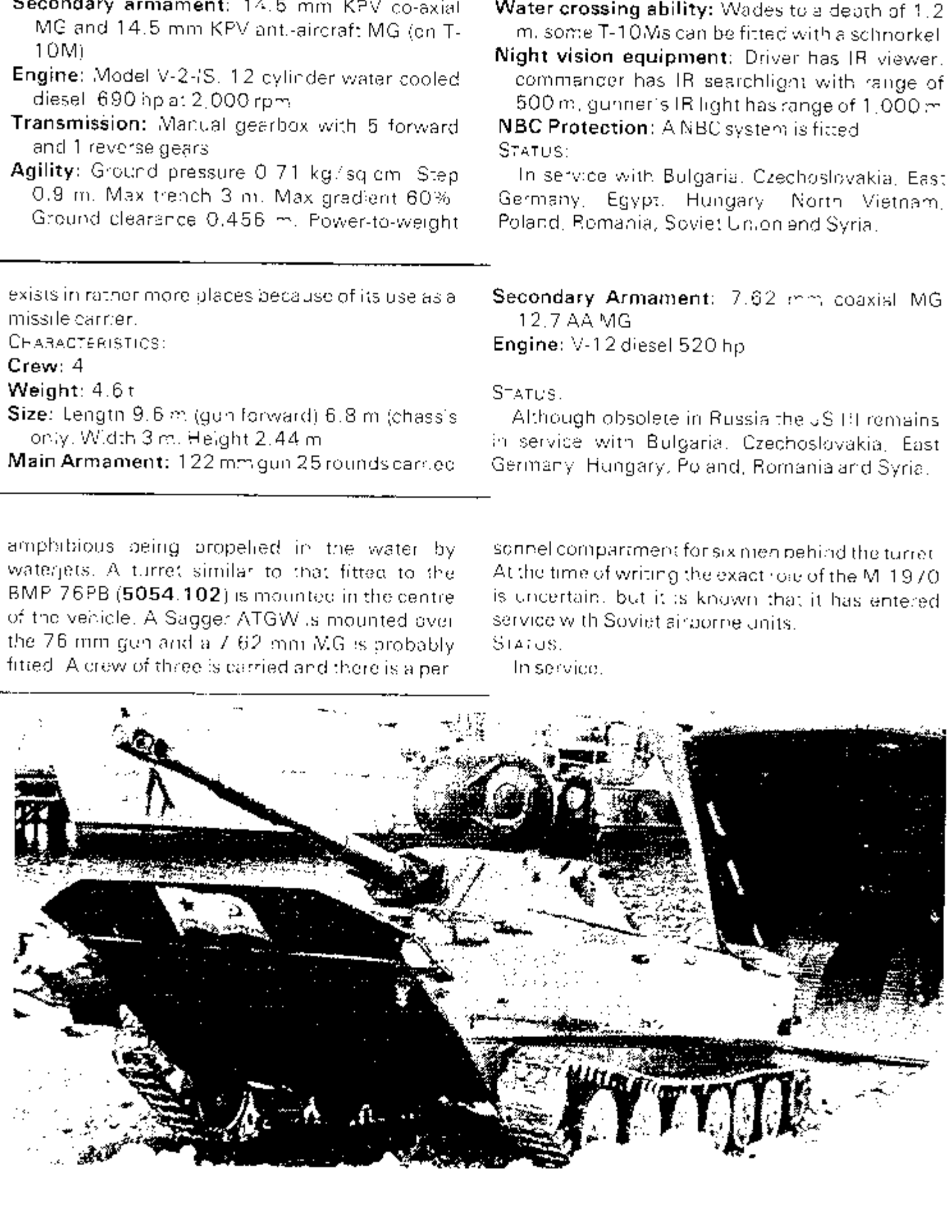
In service.

5038.102

PT76 LIGHT AMPHIBIOUS TANK

DESCRIPTION:

This light tank is used in considerable numbers as the main reconnaissance vehicle of the Soviet Army and other Warsaw Pact Armies. It was first publicly seen around 1950. It is one of a family of light track vehicles designed at the same time, which includes the ASU-85 assault gun, the Frog Rocket launcher, and the BTR 50 armoured personnel carrier. Its design has been determined by the amphibious requirement, which results in it being unnecessarily large for its weight class, and reduces its armour protection below that of other light tanks. The water jet propulsion system gives



PT76 light tank with D-56M gun (Tass)

it the capability to operate in a fast flowing river and in the open sea. The fact that the commander is also the gunner and radio operator reduces his effectiveness as an observer. It is a reliable, highly mobile vehicle, ideal as a reconnaissance platform, but with limitations as a fighting vehicle.

Apart from numerous minor variations, there are four production models of the PT-76, distinguished by differences in the main armament

Model 1. D-56T gun with no bore evacuator and a long multi-baffle brake.

Model 2. D-56TM gun with bore evacuator and double baffle brake.

PT-76B. As *Model 2* but with gun stabilisation.

Model 3. Clean barrel gun.

For details of Chinese developments of the PT-76 see entry **5103.102**.

CHARACTERISTICS:

Crew: 3 (commander, gunner, driver)

Weight: 14 t

Size: Height 2.20 m. Length (hull) 6.91 m. Width 3.18 m

Road speed / range: 44 km/h / 250 km

Main armament: 76 mm low velocity gun

Method of ranging: Visual

Max effective range: 1,000 m

Rate of fire: 6-8 rounds / min

Ammunition: 40 rounds of mixed HVAP, HE and HEAT. The HVAP and HEAT rounds should achieve penetration of APCs and other light armoured vehicles

Turret rotation: 360° in 20 secs by manual and electrical traverse

Secondary armament: 7.62 mm coaxial MG

Engine: V-6 in line diesel, 240 bhp

Transmission: Mechanical gearbox with multi-plate clutch

Agility: Ground pressure 0.49 kg/sq cm. Max step 1.06 m. Max trench 2.74 m. Max gradient 28°. Ground clearance 0.35 m. Power-to-weight ratio 17.3 bhp/tonne

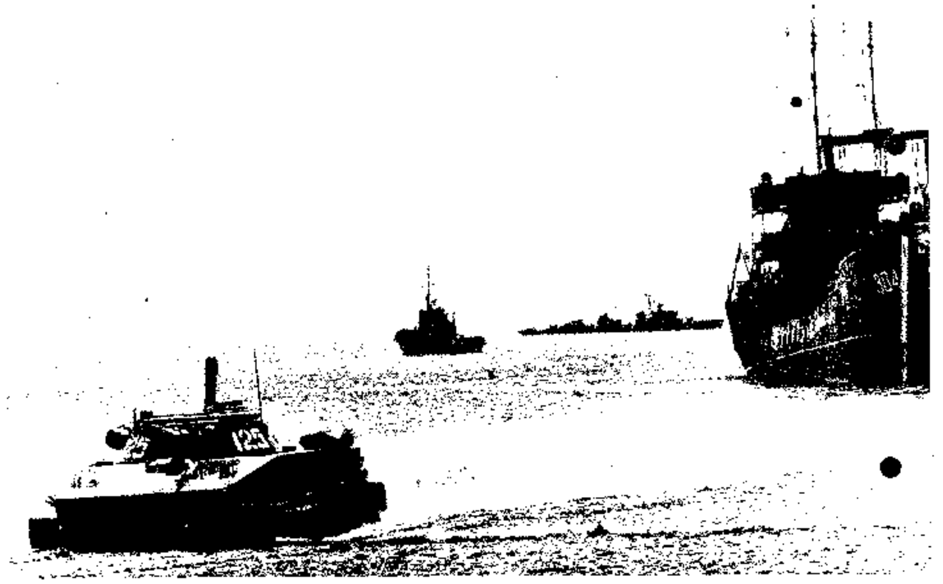
Water crossing ability: An amphibian, with water jet propulsion. Speed in water 11 kph. Designed for easy exit and entry to water.

Night vision equipment: Apparently nil, which puts it behind other Soviet AFVs in this respect

NBC Protection: None

STATUS:

The PT-76 is used by Afghanistan, Bulgaria, China, Cuba, Czechoslovakia, East Germany, Egypt, Finland, Hungary, India, Indonesia, Iraq, Laos, North Korea, North Vietnam, Pakistan, Poland, Soviet Union, Syria and Yugoslavia.



PT 76 tanks swimming ashore from vessels of the Soviet Baltic fleet

PT 76s with D-56T gun (Tass)

5050.102 ASU-57 ASSAULT GUN

DESCRIPTION:

The Soviet Army has a tradition of assault guns of limited traverse mounted on armoured chassis. The two current equipments are the light weight ASU-57, and the heavier ASU-85. ASU-57 is now a fairly old equipment having been in service certainly since 1957. It carries a 57 mm high velocity gun on a 5 tonne chassis. The armour protection is slight, there is no roof to the crew compartment, and the mobility is not up to that of more modern Soviet vehicles.

Two types of gun barrel are known to exist: one (Type A) has a multi-slot muzzle brake while the other (Type B) has a double baffle muzzle brake. Type B barrels appear to be more common than the others. There are also known to be two vehicle types, one being slightly smaller than the other and significantly lighter as a result of using light alloys in its construction

CHARACTERISTICS (standard version):

Crew: 3. Driver plus two (with room for two more)

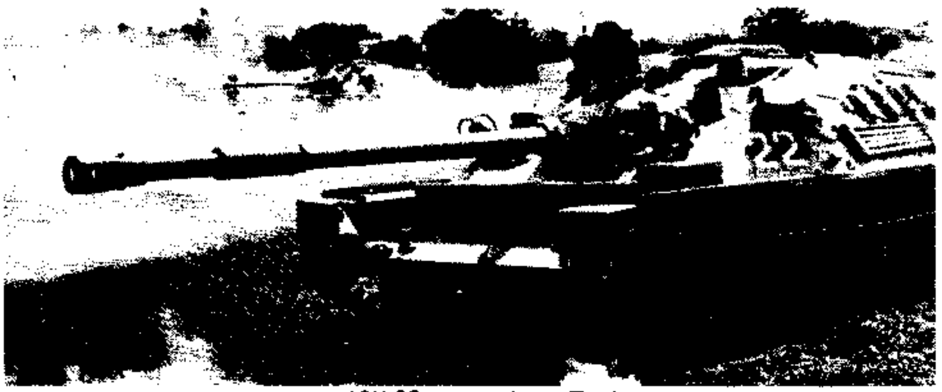
Weight: 5.4 tons

ASU 57 assault gun on an air-mobility exercise (Tass)

Size: Height 1.65 m. Length 3.73 m. Width 2.21 m
Main armament: 57 mm high velocity anti-tank gun
Engine: Diesel of 100 bhp
STATUS:
In use in Warsaw Pact countries and in Yugoslavia.

ASU-57s at speed (Novosti)

5051.102
ASU-85 ASSAULT GUN



ASU-85s on exercises (Tass)

DESCRIPTION:
The ASU-85 has been in service with the airborne units of the WPF since 1962 and is based on components of the PT-76 light tank (**5038.102**). Its main armament is an 85 mm gun which has a double baffle muzzle brake and a bore evacuator. The ASU-85 is airportable but has thin armour, the glacis plate being only 40 mm thick.
CHARACTERISTICS:
Crew: 4 (commander, gunner, loader and driver)
Size: Length 8.54 m (including gun), 6.10 m (hull). Width 2.80 m. Height 2.10 m
Road speed/range: 44 km/hr/250 km
Main armament: 85 mm gun
Elevation/depression: +15°, −4°
Traverse: Total 12°
Rate of fire: 3 to 4 rounds a minute
Ammunition: 40 rounds of HE, APHE and HVAP carried. HVAP rounds will penetrate 130 mm of armour at 1,100 m. HE projectile 9.5 kg and M/V 792 m/s. APHE projectile 9.3 kg, M/V 792 m/s and HVAP projectile weighs 5 kg and has M/V of 1,030 m/s
Secondary armament: One 7.62 mm PKT coaxial MG
Engine: V-6, 6 cylinder diesel, 240 hp at 1,800 rpm
Agility: Ground pressure 0.48 kg/sq cm. Max step 1.1 m. Max trench 2.8 m. Max gradient 70%. Ground clearance 0.4 m
Water crossing ability: Can ford to a depth of 1.1 m; no amphibious capability
Night vision equipment: IR commander's spotlight, IR searchlight over main gun, IR driving lights. More recent models have passive night vision equipment
STATUS:
In service with East Germany, Poland and the Soviet Union.

ASU-85 Assault Gun (Novosti)

5035.102
ARMOURED PERSONNEL CARRIER
BTR 50 P

DESCRIPTION:
BTR 50 P forms one of the family of light armoured vehicles of which the light tank PT-76 (**5038.102**) is the most numerous. It was introduced into the Soviet Army in 1955. It can carry a total of 15 men, making it one of the most capacious APCs in service. It has a performance similar to PT 76, and is likewise amphibious with hydrojet propulsion. It is in service with the reconnaissance units of the Soviet Army in support of PT-76. It is also in service with other Warsaw Pact armies, and in the United Arab Republic. The original version had an open top. This was modified by the addition of large roof doors to make BTR 50 PK in 1960. A command and radio version known as BTR 50 PU appeared in 1962. In all versions the crew mount and dismount through the roof openings.
CHARACTERISTICS:
Crew: 15 (3 plus 12 infantrymen)
Weight: 14 tons
Size: Height 2.0 m. Length 6.90 m. Width 3.18 m
Road speed/range: 43 km/h/250 km
Armament: Up to four MGs can be carried on roof mountings, of calibre 14.5 mm, 12.7 mm or 7.62 mm as desired
Engine: 6 cylinder, water-cooled diesel of 240 bhp

BTR-50PK armoured personnel carriers (Tass)

Transmission: Conventional manual gearbox with 5 forward, one reverse, gears, and dry plate clutch
Agility: Ground pressure 0.63 kg/sq cm. Max step 0.19 m. Max trench 2.8 m. Max gradient 30° (1 in 1.75). Ground clearance 0.35 m. Power-to-weight ratio 17 bhp/tonne
Water crossing ability: Amphibian propelled by

twin hydro-jets at 10 km/h

Night fighting equipment: Latest vehicles are fitted with IR headlamps and driver's IR viewer

NBC Protection: Basic BTR 50P has no NBC system, but systems are fitted to BTR-50PK and BTR-50PU

Variants: A Czechoslovak version of BTR 50 P known as OT 62 (Topas) has twin cupolas at the front, the right hand one mounting a turret with a 7.62 mm MG and 82 mm rocket launcher (**5109.102**)

STATUS:

In service with Albania, Bulgaria, China, Czechoslovakia, East Germany, Egypt, Finland, Hungary, India, Iran, North Vietnam, Poland, Romania, Somalia, Soviet Union, Syria, Yugoslavia.

A group of BTR-50PU command and radio vehicles provide an umpire headquarters on an exercise (Tass)

5054.102
ARMOURED PERSONNEL CARRIER
BMP-76 PB

DESCRIPTION:

This vehicle, which first appeared in a public display in 1967, hence its former NATO designation M1967 until the Russian designation was known, is in the forefront of the world's Armoured Personnel Carriers. The only other APC which matches its combination of mobility, fire power and protection is the German Marder (**5013.102**), which is bigger, heavier, and certainly considerably more expensive. It is the first Soviet APC that has been developed from the start as such, for it is not an adaptation of any other vehicle. It does, however, use some of the components of the PT 76 family (**5038.102**). It is likely to replace both BTR 50 (**5035.102**) and BTR 60 (**5034.102**) as the standard APC of the Soviet Army.

BMP-76 PB is an extremely interesting vehicle. It represents a radical change in the Soviet Army's concept of mechanised infantry operations. BTR 50 and BTR 60 are little more than 'armoured taxis' designed to carry a large body of infantry with some slight armoured protection into the vicinity of the battlefield, and there to leave them to proceed to the objective on foot. BMP-76 PB, like the German Marder, is designed to accompany the tanks into the assault and right onto and beyond the objective. It is the sort of vehicle the US Army is specifying for the Mechanised Infantry Combat Vehicle (MICV) (**5505.102**). But unlike the US vehicle, BMP-76 PB is already in service.

Although BMP-76 PB is an amphibian, it does not employ the hydrojets used in PT 76, but obtains its propulsion in water from the tracks. The engine is right front, with the driver on the left looking down a long sloping front plate which has a rather strange ridged surface, probably designed as a strengthening device. The drive is taken to the front sprocket. Directly behind the driver, and certainly with a very restricted view forward and rear when closed down, is the commander. Behind him, in the centre of the vehicle, is the one-man turret containing a 76 mm gun. It is believed that this gun fires a fin-stabilised HEAT round to a range of about 1,000 m. However, clearly the rate of fire is slow if the gunner is also the loader. Behind the turret sits a section of 8 infantrymen, sitting back to back on a wooden bench down the middle of the vehicle. They must be extremely cramped, and would have difficulty in using their weapons, as proposed, through the weapon ports which exist in the side of the compartment. Exit for the infantry section is through two rear doors, which are believed to have fuel tanks incorporated into them.

The combination of effective anti-armour fire power, high mobility and adequate protection which BMP-76 PB represents, makes it a formidable addition to the armoury of the Soviet Army.

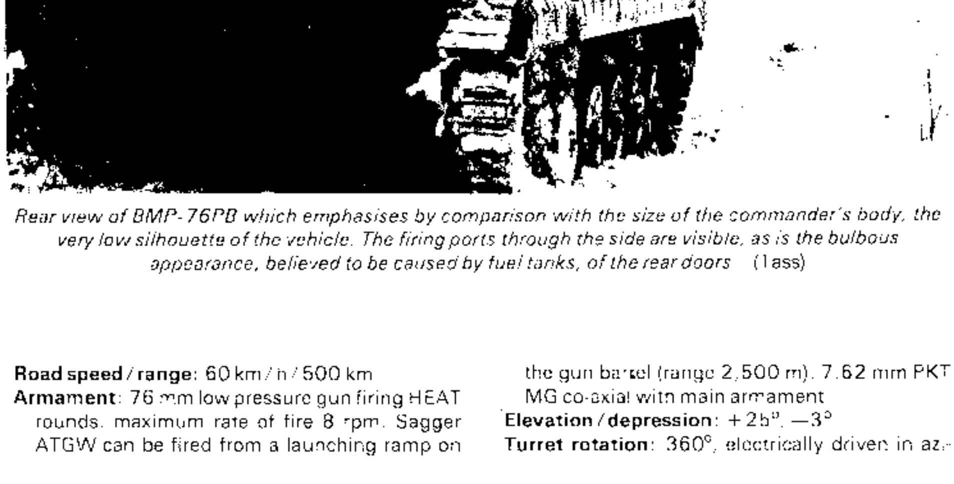
CHARACTERISTICS:

Crew: 3 plus 8 infantrymen

Weight: 12 tonnes

Size: Length 6.3 m Width 3.05 m. Height 1.83 m (including turret)

Front view of BMP-76PB showing the positions of gunner, commander and driver, the ridges on the front plate, and the 76 mm gun (Tass)



Rear view of BMP-76PB which emphasises by comparison with the size of the commander's body, the very low silhouette of the vehicle. The firing ports through the side are visible, as is the bulbous appearance, believed to be caused by fuel tanks, of the rear doors (Tass)

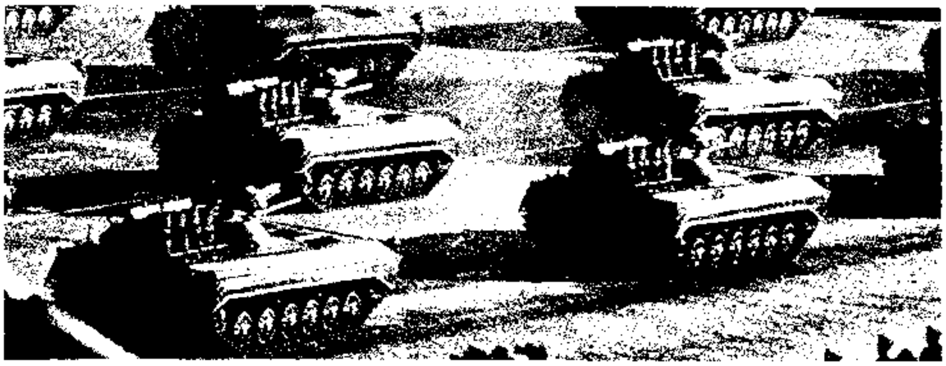
Road speed/range: 60 km/h/500 km

Armament: 76 mm low pressure gun firing HEAT rounds, maximum rate of fire 8 rpm. Sagger ATGW can be fired from a launching ramp on the gun barrel (range 2,500 m). 7.62 mm PKT MG co-axial with main armament

Elevation/depression: +25°, −3°

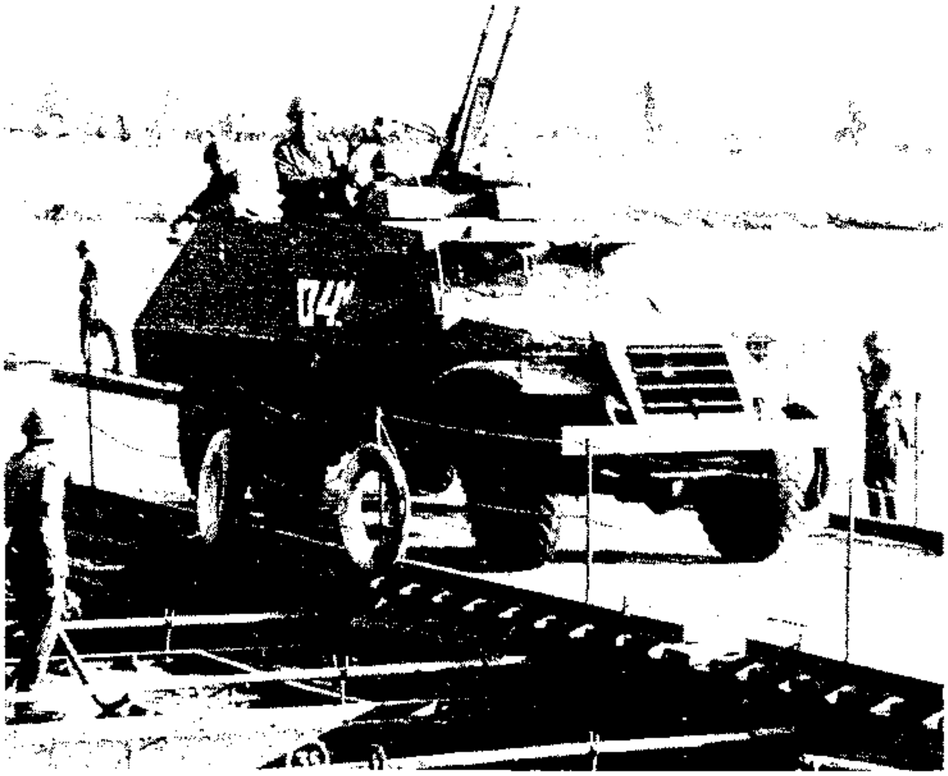
Turret rotation: 360°, electrically driven in az-

muth. Hand elevation
Engine: V 6, 6 cylinder diesel 280 hp
Agility: Max step 1.1 m. Max trench 2 m. Gradient 60%. Ground clearance 0.4 m
Water crossing ability: Amphibious, propelled in the water by its tracks at 6 km/hr
Night vision aids: IR searchlight fitted to commanders cupola. IR sight for gunner and an IR viewer for both commander and driver
NBC protection: The vehicle has a NBC system
STATUS:
In service with members of the WPF including Poland and the Soviet Union. Late in 1973 some were delivered to Egypt.



BMP-76PBs on parade. The Sagger missiles mounted above the main gun can be seen. The cramped space available to the 8 infantrymen is evident (Tass)

5082.102
ARMOURED PERSONNEL CARRIER
BTR-152
DESCRIPTION:
This is an early wheeled APC that in its original version dates from the immediate post-war years. It has, however, gone through several marks, the last of which appears to date from the early 1960s, and the vehicle is still in service in many countries. Original models were based on the ZIL 151 chassis but the ZIL-157 was used for later models (BTR-152V).
Ignoring minor variants there are three versions of the vehicle – a basic APC armed with a 7.62 mm or 12.7 mm MG, a command vehicle, normally unarmed, with a higher roof (BTR-152U) and an AA vehicle fitted with twin 14.5 mm AA guns.
CHARACTERISTICS:
Weight: 8.6 tons
Engine: Petrol. 110 bhp at 3,000 rev/min
Road speed/range: 75 km/h/600 km
Length: 6.7 m
Width: 2.35 m
Height: 2.0 m (as APC)
Crew: 2 plus 15 men (as APC)
STATUS:
Operational in Warsaw Pact countries and in almost every other country that has ever acquired military equipment from Russia.



BTR-152V APC with twin 14.5 mm AA guns (Novosti)

5034.102
ARMOURED PERSONNEL CARRIER
BTR-60
DESCRIPTION:
This 8-wheeled vehicle was first on public view at the 1961 Moscow parade, as an open top armoured personnel carrier with a crew of 14 men (driver plus 13 infantrymen), and this version is known as BTR-60P. In 1964, a hard top version (BTR 60 PK) appeared, and this was followed in 1965 by a version (BTR-60 PB) with two front cupolas for driver and co-driver, and a small MG turret for the commander. All versions are still in service with Soviet Army, though the original open-top version is now obsolescent. They are the standard equipment of the Motorised Infantry Battalions and are also seen in the Reconnaissance Battalions. They are also in service with the East German and Romanian Armies. The vehicle is an amphibian, with hydro-jet propulsion in the water, and has a good cross-country performance in conditions that favour wheels. It is believed however that the suspension is inadequate for hard driving over rough ground and this is a tactical limitation. Clearly the need for the crew to mount and dismount through the top hatches is also a tactical disadvantage. It is likely that the BTR-60 range will be gradually replaced by BMP-76PB (**5054.102**) during the 1970s
CHARACTERISTICS (apply to BTR-60 PB, unless stated):
Crew: 12 (driver, commander plus 10 infantrymen) (14 for BTR 60 P and 60 PK)

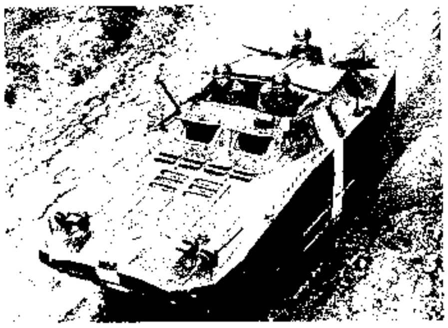
BTR-60P eight wheeled personnel carrier, in the open topped version

Weight: 10 tons
Size: Height (to top of turret) 2.29 m. Length 7.20 m. Width 2.80 m
Road speed/range: 80 km/h/500 km
Armament: 14.5 mm heavy MG and 7.62 mm MG in turret mounting. Sometimes has a rocket/flare launcher on right hand track guard and an anti tank rocket launcher fitted over the left hand track guard (BTR 60P and 60 PK have one 7.62 mm MG)
Elevation/depression: +30°, −10°
Turret rotation: 360°, manually traversed

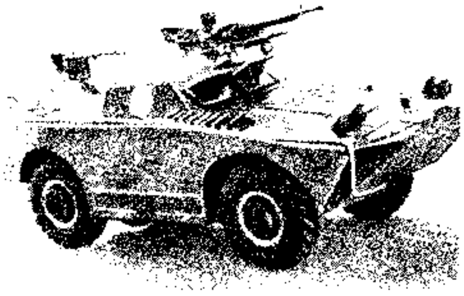
Engines: Two 6-cylinder GAZ-40P water cooled petrol engines located at the rear of the vehicle. 90 bhp at 3,400 rpm from each engine. 180 bhp
Water crossing ability: Swims, propulsion by single hydrojet, steering in water by wheels and (possibly) small rudders. Speed in water 10 km/h
Night vision devices: Driver's IR receiver for use with filtered headlamps
NBC Protection: Nil, except for that afforded by the armour
STATUS:
In service with Bulgaria, Cuba, East Germany, Egypt, Iran, Libya, Mongolia, Poland, Romania, Soviet Union, Syria and Yugoslavia.

BTR 60PK (hard top) version (Tass)

5037.102
RECONNAISSANCE CAR
BRDM-1/BTR40P
DESCRIPTION:
The history of BRDM-1 goes back to BTR-40 of 1945-48 vintage, which was almost a direct copy of the famous US Army White Scout car. This later was given an armoured top to become BTR-40K in the early 1950s. A major re-design of this vehicle, giving it swimming capability with hydrojet propulsion, and a greatly improved cross-country performance by means of four additional wheels that could be lowered between the front and back wheels, produced BRDM-1 or BTR-40P. These were manufactured in large quantities between 1960 and 1966, and formed the mainstay of the Soviet reconnaissance forces during these years. They have also been supplied to other Warsaw Pact armies, to the United Arab Republic, Cuba, and elsewhere. They are now being replaced by BRDM-2 in the Soviet Army.
CHARACTERISTICS:
Crew: 5 (commander, driver, plus 3)
Weight: 5 6 tons
Size: Height 1.9 m. Length 5.7 m. Width 2.25 m
Road speed/range: 80 km/h/500 km



BRDM-1 on the move



BRDM-1 shown here with a 12.5 mm MG mounted on roof

Armament: One 7.62 mm MG on front mounting for commander. Sometimes another MG on a rear mounting
Engine: 6-cylinder petrol engine, 3.48 litres. 90 bhp at 3,400 rpm. Engine and transmission are at the front of the vehicle
Drive: Normally 4 × 4, but an additional four wheels can be dropped to give 8 wheel drive across country
Power-to-weight ratio: 13.8 bhp/ton
Water crossing capability: Swims with hydrojet propulsion
Variants: The following variants of the basic vehicle are known
- Radio and command vehicle
- NBC monitoring vehicle
- Anti-tank guided weapon vehicles for Snapper, Swatter or Sagger missiles.

5036.102
RECONNAISSANCE CAR
BRDM-2/BTR40PB
DESCRIPTION:
The BRDM-2, or BTR-40PB as it is sometimes known, was first seen in 1966 and since then has replaced some of the earlier BRDM-1 vehicles in members of the WPF. The BRDM-2 is bigger than the earlier vehicle and has two engines mounted at the rear; it retains the rectractable auxiliary wheels. The turret fitted is the same as that mounted on the BTR-60PB (**5034.102**) and the Czech OT 64 Model 3 (**5074.102**), and is unusual in that it has no top hatch opening.
CHARACTERISTICS:
Crew: 4 (commander, gunner, driver and co-driver)
Weight: 7 tonnes
Size: Length 5.5 m. Width 2 18 m. Height 2 15 m
Road speed/range: 100 km/h/750 km
Armament: 14.5 mm KPVI and 7.62 mm PKT MG turret mounted
Elevation/depression: +30°, −10°
Turret rotation: 360° (hand)
Engines: Two M-21 4 cylinder petrol engines. 70 hp at 4,000 rpm (each)
Agility: Max step 0.47 m. Max trench 1.25 m. Gradient 60%. Ground clearance 0.315 m
Water crossing ability: Swims, with propulsion by twin hydrojets. Water speed 10 km/hr
Night vision aids: IR spotlight and IR driving lights
NBC Protection: NBC system is fitted

A group of BRDM-2 Armoured Cars showing the side by-side positioning of the commander and the driver, and the two man turret mounting a 14.5 mm MG and a 7.62 mm MG. The retractable auxiliary wheels can also be seen on the second vehicle from the left (Tass)

VARIANTS:
BTR-40PB (Sagger) This is a BTR-40PB with the turret removed and a launching system for six Sagger ATGW (**2950.111**) fitted. It was used in the Middle East campaign of 1973.
BTR-40PB (SAM) – This is a BTR-40PB with the turret removed and replaced by a launching system for 4 or 8 SA-7 (Grail) anti-aircraft missiles (see entry **2941.131**)
The Hungarians have a similar vehicle called the FUG M-1966 (**2189.102**).
STATUS:
The BTR-40PB is used by members of the WPF including East Germany, Poland and the Soviet Union. It is also used by Egypt and Syria.
